Revision History

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.0	First release of specification.	January 31, 2006
2.1	Second release	January 23, 2007
2.1a	UEFI 2.1 incorporating Errata through 4-27-07	April 27, 2007
2.1b	51 Long physical blocks updates	December 11, 2007
2.1b	156 SendForm API Errata	December 11, 2007
2.1b	158 Errata to the UEFI 2.1 configuration sections	December 11, 2007
2.1b	159 Adjust some of the #define names in the Simple Text Input Ex protocol	December 11, 2007
2.1b	160 Clean up references to PCIR	December 11, 2007
2.1b	162 UEFI PIWG Device Path Errata	December 11, 2007
2.1b	164 Update to USB2_HC_PROTOCOL Table	December 11, 2007
2.1b	165 Fix EFI_GRAPHICS_OUTPUT_PIXEL	December 11, 2007
2.1b	168 Remove LOAD_OPTION_GRAPHICS	December 11, 2007
2.1b	170 (Addition of) Driver Family Override Protocol	December 11, 2007
2.1b	172 Typo for ResetSystem()	December 11, 2007
2.1b	173 Minor changes to the description of two of the fields in the Common Platform Error Record, in Appendix N	December 11, 2007
2.1b	174 Error record addition for dma remapping units	December 11, 2007
2.1b	175 Update to SendForm API	December 11, 2007
2.1b	177 remove ending paragraph (editing text) in section 9.6	December 11, 2007
2.1b	181 Correct MNP GUID collision	December 11, 2007
2.1b	182 Clarify EFI_MTFTP4_TOKEN	December 11, 2007

Unified Extensible Firmware Interface Specification

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.1b	184 SNIA/DDF Wording Update	December 11, 2007
2.1b	185 Change EFI term to UEFI for consistency	December 11, 2007
2.1b	186 change PCIR struct to match PCI FW Spec 3.0	December 11, 2007
2.1b	187 Clarify input protocols.	December 11, 2007
2.1b	190 Extensive errata form UCST including OP codes changes ro resolve conflicts.	December 11, 2007
2.1b	197 EFI Loaded Image Device Path Protocol	December 11, 2007
2.1b	205 Change LoadImage() parameter name from FilePath to DevicePath; ends confusion with EFI_LOADED_IMAGE_PROTOCOL	December 11, 2007
2.1c	52 New GUID for Driver Diagnostics and Driver Configuration Protocols with new GUID	June 5, 2008
2.1c	54 ACPI Table Protocol GUID Update	June 5, 2008
2.1c	55 Clarification on UpdateCapsule	June 5, 2008
2.1c	56 Clarification on ResetSystem	June 5, 2008
2.1c	57 Clarify text for Extended SCSI Pass Thru Protocol.GetNextTargetLun()	June 5, 2008
2.1c	58 Language update for EfiReservedMemory type usage	June 5, 2008
2.1c	59 Add return code to Diagnostics Protocol	June 5, 2008
2.1c	60 iSCSI Device Path Update	June 5, 2008
2.1c	189 Graphics Output Protocol clarification	June 5, 2008
2.1c	193 Loaded Image device paths for EFI Drivers loaded from PCI Option ROMs	June 5, 2008
2.1c	203 Platform Error Record - x64 register state errata	June 5, 2008
2.1c	206 Clarify return values for extended scsi passthru protocol	June 5, 2008
2.1c	207 Updated Wording for the File Path	June 5, 2008
2.1c	208 Driver Protocol Names and GUIDs	June 5, 2008
2.1c	209 ESP number/location clarifications	June 5, 2008
2.1c	213 UEFI HII Errata	June 5, 2008
2.1c	214 Device_IO + typos	June 5, 2008
2.1c	216 UEFI 2.1 text corrections	June 5, 2008
2.1c	217 EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL.Query() Update	June 5, 2008
2.1c	218 SATA update to section 9.3.5.6	June 5, 2008
2.1c	219 IA-32 and x64 stack need to be 16-byte aligned	June 5, 2008
2.1c	220 Replace references to RFC 3066 to RFC 4646	June 5, 2008
2.1c	221 Image Block Structure name typos in 27.3.7.2	June 5, 2008

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.1c	244 Replace references to EFI_FIRMWARE_VOLUME_INFO_PPI with EFI_PEI_FIRMWARE_VOLUME_INFO_PPI	June 5, 2008
2.1c	245 Remove extraneous text in Chapter 29	June 5, 2008
2.1c	246 New return code	June 5, 2008
2.1c	248 Correction to text in Chapter 8.2 of UEFI 2.1b	June 5, 2008
2.1c	249 Latest update to UCST Errata list	June 5, 2008
2.1c	266 PKCS11.5 structure does not correctly specify the portion of the cited RFC that pertains to the certificate struct/algorithm	June 5, 2008
2.1c	278 Change references to EFI_SIMPLE_INPUT_PROTOCOL into EFI_SIMPLE_TEXT_INPUT_PROTOCOL	June 5, 2008
2.1c	280 Some minor errata to keyboard related topics	June 5, 2008
2.1c	281 Runtime memory allocation	June 5, 2008
2.1c	283 Minor update to clarify a typedef/return code in HII	June 5, 2008
2.1c	Re-format Revision History from bulleted lists to one row per Mantis ticket/ Engineering Change Request	June 5, 2008
2.2	157 Floating-Point ABI Changes For X86, X64 & Itanium	July 25, 2008
2.2	169 EFI Driver Health Protocol	July 25, 2008
2.2	198 GUID Partition Entry Attributes Clarification and Definition	July 25, 2008
2.2	199 FTP API	July 25, 2008
2.2	200 VLAN	July 25, 2008
2.2	201EAP	July 25, 2008
2.2	202 EAP Management	July 25, 2008
2.2	210 UEFI HII Animation addition	July 25, 2008
2.2	211UEFI Setup Question / Form Access Update	July 25, 2008
2.2	212 UEFI HII Standards Mapping	July 25, 2008
2.2	215 new Start() RemainingDevicePath Syntax	July 25, 2008
2.2	237 UEFI User Identification Proposal (from USST)	July 25, 2008
2.2	242 UEFI ATA Pass-Through Protocol	July 25, 2008
2.2	279 Firmware/OS Trusted Key Exchange and Image Validation	July 25, 2008
2.2	282 Updated Requirements Section For ATA Pass Through (M242)	July 25, 2008
2.2	288 Additional wording fixes for GPT Entry Attribute Bit 1	July 25, 2008
2.2	291 HII Errata / Update	July 25, 2008
2.2	294 LocateDevicePath with multi-instance device path	July 25, 2008
2.2	299 PIWG Firmware File/Firmware Volume Typo Errata	July 25, 2008
2.2	300 MTFTP errata	July 25, 2008
2.2	301 Errata to the Authentication Protocol	July 25, 2008
2.2	303 Add ability to have a capsule that initiates a reset & doesn't return to the caller	July 25, 2008
2.2	304 Errata to UpdateCapsule()	July 25, 2008
2.2	306 Some errata to the animation support	July 25, 2008

Unified Extensible Firmware Interface Specification

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.2	309 IPv6 Address display format clarification	July 25, 2008
2.2	310 EFI UDPv6 Protocol	July 25, 2008
2.2	311EFI DHCPv6 Protocol	July 25, 2008
2.2	312 EFI IPv6 Protocol	July 25, 2008
2.2	313 EFI IPv6 Configuration Protocol	July 25, 2008
2.2	314 EFI MTFTP6 Protocol	July 25, 2008
2.2	315 EFI TCP6 Protocol	July 25, 2008
2.2	319 UEFI IPSec protocol	July 25, 2008
2.2	320 Clarification for WIN_CERTIFICATE types & relationship with signature database types	July 25, 2008
2.2	321Enable PCIe 2.0 and beyond support in the UEFI error records	July 25, 2008
2.2	322 Chapter 2 updates for IP6 net stack	July 25, 2008
2.2	323 VLAN modification because of IPV6	July 25, 2008
2.2	324 ATA Pass-Thru ECR Update	July 25, 2008
2.2	325 Minor correction 28.3.8.3.20	July 25, 2008
2.2	327 Clarify the support in DHCP4 protocol for "Inform" (DHCPINFORM) messages.	Sept. 25, 2008
2.2	330 EFI_IFR_REF: Change cross reference to a question	Sept. 25, 2008
2.2	331 Definition for EFI_BROWSER_ACTION and the related #defines were not present--Insert.	Sept. 25, 2008
2.2	332 Correct SendForm description Type, PackageGuid and FormsetGuid parameters	Sept. 25, 2008
2.2	333 Correct the incorrect ';' at the end of EFI_GUID #defines	Sept. 25, 2008
2.2	335 User Authentication errata	Sept. 25, 2008
2.2	337 Replace the EFI_CRYPT_HANDLE reference (in the IPSec API)with a self-contained, independent definition.	Sept. 25, 2008
2.2	339 Update missing TPL restrictions	Sept. 25, 2008
2.2	340 UEFI 2.2 Editorial / Formatting Issues	Sept. 25, 2008
2.2	343 Correct missing parameter for User() function in EFI_USER_CREDENTIAL_PROTOCOL	Sept. 25, 2008
2.2	344 Correct missing status codes returned section for Form() in EFI_USER_CREDENTIAL_PROTOCOL.	Sept. 25, 2008
2.2	346 Nest, Sections 10.11 & 10.12 Under 10.10	Sept. 25, 2008
2.2	347 Replace first paragraph of the "Description" section for the ExitBootServices()	Sept. 25, 2008
2.2	334 Standardized "Unicode" References	Jan. 11, 2009
2.2	348 EFI_IFR_RESET_BUTTON is incorrectly listed as a question	Jan. 11, 2009
2.2	350 EFI_HII_STRING_PROTOCOL Typos	Jan. 11, 2009
2.2	351 Fix an unaligned field in a device path	Jan. 11, 2009
2.2	357 Clarify EFI_IFR_DISABLE_IF behavior with regard to dynamic values	Jan. 11, 2009
2.2	394 Omission in EFI_USB2_HC_PROTOCOL	Jan. 11, 2009

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.2	397 PCI CopyMem() misspelling	Jan. 11, 2009
2.2	398 Update to M348 to fix small typo	Jan. 11, 2009
2.2 errata	358 Missing signature for UEFI 2.2.	Feb. 12, 2009
2.2 errata	359 TPL Table	Feb. 12, 2009
2.2 errata	361 UEFI 2.2 Typos & Formatting Issues	Feb. 12, 2009
2.2 errata	362 UEFI 2.2 Typos (Next)	Feb. 12, 2009
2.2 errata	364 UEFI 2.2 Typos & Formatting Issues (ch. 9)	Feb. 12, 2009
2.2 errata	366 UEFI 2.x: Erroneous references to EFI_BOOT_SERVICES_TABLE, EFI_RUNTIME_SERVICES_TABLE	Feb. 12, 2009
2.2 errata	368 EFI_FONT_DISPLAY_INFO.FontInfo description incorrect	Feb. 12, 2009
2.2 errata	370 EFI_SYSTEM_TABLE Errata (UEFI 2.1/UEFI 2.2)	Feb. 12, 2009
2.2 errata	371 UEFI 2.1 & UEFI 2.2 Typos (ch. 10)	Feb. 12, 2009
2.2 errata	372 UEFI 2.2 remove "Draft for Review"	Feb. 12, 2009
2.2 errata	373 UEFI 2.2, chs. 9.5 & 9.6.2 & 9.6.3 (Device Path) Errata	Feb. 12, 2009
2.2 errata	374 UEFI 2.1 & UEFI 2.2 Errata (10.7-10.10)	Feb. 12, 2009
2.2 errata	375 Extra periods errata in UEFI 2.2	Feb. 12, 2009
2.2 errata	377 Missing BLT buffer figure.	Feb. 12, 2009
2.2 errata	378 UEFI 2.1 & UEFI 2.2 HII Callback Clarifications	Feb. 12, 2009
2.2 errata	379 UEFI 2.1/UEFI 2.2 HII-Related Errata	Feb. 12, 2009
2.2 errata	384 Fix HII package description omission.	Feb. 12, 2009
2.2 errata	387 UEFI 2.1/UEFI 2.2 Errata (ch. 12)	Feb. 12, 2009
2.2 errata	389 UEFI 2.2 HII-Related Formatting Issues	Feb. 12, 2009
2.2 errata	390 UEFI 2.2 Miscellaneous HII-related errata	Feb. 12, 2009
2.2 errata	391 Polarity of INCONSISTENT_IF and NO_SUBMIT_IF IFR opcodes wrong	Feb. 12, 2009
2.2 errata	392 MBR errata in UEFI 2.2	Feb. 12, 2009
2.2 errata	393 UEFI 2.1/2.2 Boot Manager Behavior Clarification	Feb. 12, 2009
2.2 errata	400 FreePool() description error	Feb. 12, 2009
2.2 errata	404 Remove constraint form EFI_TIME.Year comment	Feb. 12, 2009
2.2 errata	429 EFI_HASH_SERVICE_BINDING_PROTOCOL GUID define misses _GUID	Feb. 12, 2009
2.3	326 Add Firmware Management Protocol	Feb. 12, 2009
2.3	376 Add ARM processor binding to UEFI	Jan. 12, 2009
2.3	388 Add HII callback types (FORM_OPEN, FORM_CLOSE) when a form is opened or closed.	Feb. 12, 2009
2.3	394 Omission in EFI_USB2_HC_PROTOCOL	Feb. 12, 2009
2.3	395 New "Non-removable Media Boot Behavior" section	Feb. 12, 2009
2.3	406 Missing EFI System Table Revision In UEFI 2.3 Draft	Feb. 12, 2009
2.3	408 ARM Binding corrections	Feb. 12, 2009
2.3	431 UEFI 2.3 Feb Draft: Section 30.4	Feb. 12, 2009

Unified Extensible Firmware Interface Specification

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.3	432 UEFI 2.3 Feb Draft: Appendix M.	Feb. 12, 2009
2.3	434 UEFI 2.3 Feb Draft: 28.3.8.3.58	Feb. 12, 2009
2.3	435 Partition Signature clarification	Feb. 12, 2009
2.3	436 UEFI 2.3 split Figure 88 into 3 figures	Feb. 12, 2009
2.3	410 UNDI buffer usage	Feb 18, 2009
2.3	413 Correct the definition of UEFI_CONFIG_LANG	Feb 18, 2009
2.3	418 Change Appendix O from "UEFI ACPI Table" to "UEFI ACPI Data	Feb 18, 2009
2.3	437 Errata to 2.3 draft material from UEFI Spec 2_3_Draft_Jan29	Feb 18, 2009
2.3	438 UEFI 2.3 Feb 13 Draft: Chapter 28 Formatting Issues	Feb 18, 2009
2.3	439 Incorrect definitions of UEFI_CONFIG_LANG and UEFI_CONFIG_LANG_2 in UEFI 2.3 Feb18 draft	Feb 25, 2009
2.3	440 Change the defined type of EFI_STATUs from INTN to UINTN	May 7, 2009
2.3	442 Section 28.3.8.3.64, EFI_IFR_SET, Prototype, lines 3-8, indent by 2 spaces	May 7, 2009
2.3	443 Section 28.3.8.3.38, EFI_IFR_MAP, Prototype, line 4, outdent 2 spaces.	May 7, 2009
2.3	444 Form Set Syntax: Section 28.2.5.1.1, section should be subheading, not heading level 5; Section 28.2.5.1, Syntax, line 3, text after := is not aligned with other text on line 2, 4	May 7, 2009
2.3	445 Table 194: EFI_IFR_FORM_MAP_OP, 2nd column should be 0x5d (not 05xd)	May 7, 2009
2.3	446 Section 28.2.5.2 Forms, Syntax, change 3rd line to: form := EFI_IFR_FORM form-tag-list EFI_IFR_FORM_MAP form-tag-list	May 7, 2009
2.3	447Section 28.2.5.11.2 Moving Forms, Update line that starts with EFI_IFR_FORM to: EFI_IFR_FORM or EFI_IFR_FORM_MAP (and all references in EFI_IFR_REF)	May 7, 2009
2.3	448 Section 28.2.5.4 Questions, Syntax, Update question-option-tag; Add EFI_IFR_READ and EFI_IFR_WRITE in the question syntax.	May 7, 2009
2.3	449 Add missing EFI_IFR_GET, EFI_IFR_SET and EFI_IFR_MAP to the syntax. Section 28.2.5.7.	May 7, 2009
2.3	450 Missing opcode headers and formatting, section 28.3.8.3.x.	May 7, 2009
2.3	452 Support to dynamically detect media errata - SNP	May 7, 2009
2.3	453 Errata to support dynamic media detection - UNDI	May 7, 2009
2.3	454 Dynamic support of media detection - network stack	May 7, 2009
2.3	456 How to handle PXE boot w/o NII Section 21.3	May 7, 2009
2.3	457 Change KeyData.PackedValue to 0x40000200, page 63.	May 7, 2009
2.3	460 Chapter 2.6 language update	May 7, 2009
2.3	461IP4 Mode Data definition update	May 7, 2009
2.3	462 ExitBootServices timers deactivation	May 7, 2009
2.3	463 Update EFI_IP6_PROTOCOL.Neighbors() API	May 7, 2009
2.3 A	477 Text adjustment to ConfigAccess/ConfigRouting	Sept 15, 2009

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.3 A	478 Update to ALTCFG references	Sept 15, 2009
2.3 A	490 Correction 28.2.5.6, Table 185. Information for Types of Storage	Sept 15, 2009
2.3 A	505 TCP4/MTFTP4 status codes	Sept 15, 2009
2.3 A	506 TCP6/MTFTP6 Status Code Definition	Sept 15, 2009
2.3 A	513 add support for gateways in ipv4 & ipv6 device path nodes	Sept 15, 2009
2.3 A	516 User Identity Protocol bugs	Sept 15, 2009
2.3 A	517 IP stack related protocol update	Sept 15, 2009
2.3 A	518 typos	Sept 15, 2009
2.3 A	522 Bugs in EFI_CERT_BLOCK_RSA_2048_SHA256, iSCSI device path, CHAP device path	Sept 15, 2009
2.3 B	215 previously added to Device Driver (wrong), now BusDriver (correct)	Dec. 15, 2009
2.3 B	301 Errata to the Authentication Protocol	Dec. 15, 2009
2.3 B	431 UEFI 2.3 Feb Draft: Section 30.4	Feb. 24, 2010
2.3 B	454 Dynamic support of media detection - network stack	Dec. 15, 2009
2.3 B	460 Section 2.6 language change	Dec. 15, 2009
2.3 B	476 Text adjustment to ConfigAccess & ConfigRouting	Dec. 15, 2009
2.3 B	479 TPM guideline added to section 2.6.2	Dec. 15, 2009
2.3 B	507 Clarify ACPI Protocol's position on checksums	Dec. 15, 2009
2.3 B	514 HII Configuration String Syntax Clarification	Feb. 24, 2010
2.3 B	515 Authenticated Variables Clarification	Feb. 24, 2010
2.3 B	518 Typos in the UEFI2.3 specification	Feb. 24, 2010
2.3 B	519 Add console table (chapt 11) for EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL	Dec. 15, 2009
2.3 B	531 Clarify HII Variable Storage	Dec. 15, 2009
2.3 B	532 "Legacy BIOS Bootable" GPT attribute	Dec. 15, 2009
2.3 B	533 GPT editorial cleanup	Dec. 15, 2009
2.3 B	534 Size of Partition Entry restriction	Dec. 15, 2009
2.3 B	536 IPsec errata	Dec. 15, 2009
2.3 B	537 Add missing ACPI ADR Device Path Representation	Dec. 15, 2009
2.3 B	539 CHAP node fix for iSCSI	Dec. 15, 2009
2.3 B	540 Register name usage	Dec. 15, 2009
2.3 B	542 Device Path Description Changes	Dec. 15, 2009
2.3 B	545 Action parameter of the EFI_HII_CONFIG_ACCESS_PROTOCOL.CallBack()	Dec. 15, 2009
2.3 B	546 typo in GOP definiton	Dec. 15, 2009
2.3 B	547 Clean-Up In HII Sections	Dec. 15, 2009
2.3 B	549 Binary prefix change	Dec. 15, 2009
2.3 B	556 additional IPsec errata/issues	Dec. 15, 2009

Unified Extensible Firmware Interface Specification

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.3 B	557 Corrected Image Execution Information omission & ambiguity	Dec. 15, 2009
2.3 B	558 Clarify VLAN config publication requirements	Dec. 15, 2009
2.3 B	559 Extraneous "default" tag in EFI_IFR_SECURITY grammar	Dec. 15, 2009
2.3 B	560 Correct erroneous example in ExtractConfig()	Dec. 15, 2009
2.3 B	566 Minor update to HII->NewString function description	Dec. 15, 2009
2.3 B	567 Various miscellaneous typos/updates	Feb. 24, 2010
2.3 B	568 ATA_STATUS_BLOCK name errata	Dec. 15, 2009
2.3 B	572 EFI_IFR_SECURITY should be EFI_IFR_SECURITY_OP in Table 194	Dec. 15, 2009
2.3 B	573 EFI_DESCRIPTION_STRING and EFI_DESCRIPTION_BUNDLE adjustments	Feb. 24, 2010
2.3 B	574 Add an "OPTIONAL" tag to a parameter in NewPackageList	Dec. 15, 2009
2.3 B	576 Clarifications in the Routing Protocol	Dec. 15, 2009
2.3 B	577 clarifications on the user identity protocol	Dec. 15, 2009
2.3 B	578 ATA Passthrough updates / questions	Dec. 15, 2009
2.3 B	580 ACPI_SUPPORT_PROTOCOL clarifications related to FADT and the DSDT/FACS	Dec. 15, 2009
2.3 B	583 How do we know an EFI_HANDLE is Valid/Invalid	Feb. 24, 2010
2.3 B	575 Machine hand-off/MP state modification	Feb. 24, 2010
2.3 B	584 EFI_PXE_BASE_CODE_DHCPV6_PACKET missing for pxe bc protocol	Feb. 24, 2010
2.3 B	585 Errata to EFI_IFR_SET op-code	Feb. 24, 2010
2.3 B	586 clarification of PXE2.1 specification for IPV4 interoperability issues	Feb. 24, 2010
2.3 B	587 UEFI User Identity - Naming consistency	Feb. 24, 2010
2.3 B	588 UEFI User Identity - Return codes	Feb. 24, 2010
2.3 B	589 Device path representation of IPv4/v6 text	Feb. 24, 2010
2.3 B	590 Media detect clean-up	Feb. 24, 2010
2.3 B	598 ARP is only an IPV4 concept.	Feb. 24, 2010
2.3 B	600 Update to ConfigAccess/ConfigRouting	Feb. 24, 2010
2.3 B	601 UNDI update as part of media detect changes	Feb. 24, 2010
2.3 B	605 Clarify user identity Find API	Feb. 24, 2010
2.3 B	608 more media detect clean-up	Feb. 24, 2010
2.3 C	508 Update networking references, incl ipv6	July 14, 2010
2.3 C	583 How do we know an EFI_HANDLE is Valid/Invalid	July 14, 2010
2.3 C	609 StartImage return code update	July 14, 2010
2.3 C	610 RSA data structure clarification	July 14, 2010
2.3 C	611 Language correction requested for InstallProtocolInterface() and InstallConfigurationTable(), Ref# 583	July 14, 2010

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.3 C	613 PAUSE Key	July 14, 2010
2.3 C	620 Clarification of need for Path MTU support for IPV4 and IPV6	July 14, 2010
2.3 C	621 Typos in an EFI_HII_CONFIG_ACCESS_PROTOCOL.Callback() member	July 14, 2010
2.3 C	622 Identify() function errata	July 14, 2010
2.3 C	625 Minor typo in surrogate character description section	July 14, 2010
2.3 C	632 Clarify Block IO ReadBlocks and WriteBlocks functions handling of media state change events	July 14, 2010
2.3 C	633 Explicitly Specify ACPI Table Signature Format	July 14, 2010
2.3 C	635 Missing GUID label for Config Access protocol	July 14, 2010
2.3 C	636 Mistaken Reference to "Date" inside of Boolean question description	July 14, 2010
2.3 C	637 Clarification for Date/Time Question usage in IFR expressions.	July 14, 2010
2.3 C	639 Callback() does not describe FORM_OPEN/FORM_CLOSE behavior	July 14, 2010
2.3 C	640 String Reference Cleanup	July 14, 2010
2.3 D	538 IPV6 PXE	Oct. 28, 2010
2.3 D	638 Add facility for dynamic IFR dynamic cross-references	Oct. 28, 2010
2.3 D	650 networking support errata	Oct. 28, 2010
2.3 D	651 update to IPSec for tunnel mode support	Oct. 28, 2010
2.3 D	652 Clarification to the TimeZone value usage	Oct. 28, 2010
2.3 D	653 Errata to the Appendix N (Common Platform Error Record)	Oct. 28, 2010
2.3 D	659 Clarify section length definition in the error record	Oct. 28, 2010
2.3 D	662 ARM ABI errata	Oct. 28, 2010
2.3 D	663 Update ARM Platform binding to allow OS loader to assume unaligned access support is enabled	Nov. 10, 2010
2.3 D	664 Appendix update for IPV6 network boot	Oct. 28, 2010
2.3 D	667 Clarification to the UEFI Configuration Table definition	Oct. 28, 2010
2.3.1	484 Key Management Service Protocol	Oct. 28, 2010
2.3.1	612 UEFI system Partition FAT32 data Region Alignment	Oct. 29, 2010
2.3.1	616 Security Protocol command to support encrypted HDD	Oct. 29, 2010
2.3.1	634 Forms Browser Default Behavior	Oct. 29, 2010
2.3.1	645 Non-blocking interface for BLOCK oriented devices (BLOCK_IO_EX transition to BLOCK_IO_2)	Oct. 29, 2010
2.3.1	661 USB 3.0 Updates	Oct. 29, 2010
2.3.1	484 Key Management Service (KMS) Protocol	Oct. 29, 2010
2.3.1	616 Security Protocol Command to support encrypted HDD	Jan. 17, 2011
2.3.1	634 Forms Browser Default Behavior	Jan. 17, 2011
2.3.1	671 Errata: USB device path example is incorrect	Jan. 17, 2011

Unified Extensible Firmware Interface Specification

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.3.1	674 Section 3.2: Missing variable type for SetupMode variable	Jan. 17, 2011
2.3.1	677 Section 27.2.5 & 27.6.1: Typo in X509 Signature Type	Jan. 17, 2011
2.3.1	678 Section 27.6.2: Imagehash reference needs to be removed	Jan. 17, 2011
2.3.1	679 UEFI Authenticated Variable & Signature Database Updates	Jan. 17, 2011
2.3.1	680 Netboot6 handle clarification	Jan. 17, 2011
2.3.1	681 Typo: Pg. 56	Jan. 17, 2011
2.3.1	687 Update System Table with this new #define for 2.3.1	Jan. 17, 2011
2.3.1	668 LUN implementations are not consistent	Feb. 3, 2011
2.3.1	682 [UCST] Modal Form	Feb. 3, 2011
2.3.1	686 HII - Clarify Forms Browser 'standard' user interfections.	Feb. 3, 2011
2.3.1	685 HII - New op-code to enable event initiated refresh of browser context data	Feb. 3, 2011
2.3.1	695 Add Port Ownership probing	Feb. 3, 2011
2.3.1	696 Update System Table with this new #define for EFI_SYSTEM_TABLE_REVISION	Feb. 3, 2011
2.3.1	702 Clarifications on Variable Storage for Questions	Feb. 3, 2011
2.3.1	704 Unload() definition is wrong	Feb. 3, 2011
2.3.1	705 REPC signature definition still confusing	Feb. 3, 2011
2.3.1	707 Errata revision in the EFI_IFR_VERSION format	Feb. 3, 2011
	708 Errata (non-blocking BLOCK IO)	April 5, 2011
2.3.1	709 New Callback() Action Requests Related To Individual Forms.	Feb. 3, 2011
2.3.1	478 (REVISIT) Update to ALTCFG references	March 11, 2011
2.3.1	711 SetVariable Update	March 11, 2011
2.3.1	713 Remove the errata revision from the EFI_IFR_VERSION format.	March 11, 2011
2.3.1	715 CPER Record and section field clarification	March 11, 2011
2.3.1	716 EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTarget() IN OUT parameter Target input value shall be 0xFFs	March 11, 2011
2.3.1	720 User Identification (UID) Errata – Credential Provider Enroll Clarification	March 11, 2011
2.3.1	721 User Identification (UID) Errata – SetInfo Clarification	March 11, 2011
2.3.1	722 User Identification (UID) Errata – Credential Provider Enroll Clarification	April 5, 2011
2.3.1	723 User Identification (UID) Errata – EFI User Manager Notify & Enroll Clarification	April 5, 2011
2.3.1	724 SetVariable Update 2	March 11, 2011
2.3.1	726 Errata/clean-up of EFI_DHCP4_TRANSMIT_RECEIVE_TOKEN definition	March 11, 2011
2.3.1	727 Errata on return code for User Info Identity policy record	March 11, 2011
2.3.1	728 Netboot 6 errata - DUID-UUID	March 11, 2011
2.3.1	729 Errata: clarification of Microsoft references in appendix Q	March 11, 2011

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.3.1	732 Amendment to Mantis 711: section 7.2.1.6	March 11, 2011
2.3.1	733 Errata: 27.6.1 signatureheadersize definition	March 11, 2011
2.3.1	734 SecureBoot variable	April 5, 2011
2.3.1	735 Clarification on Tape Header Format	March 11, 2011
2.3.1	736 Insert SMM Communication ACPI Table and related data structures to the UEFI Specification	April 5, 2011
2.3.1	740 Errata: signatureheadersize inconsistency corrections	April 6, 2011
2.3.1	741 Errata: corrected text for section 7.2.1.4 step 7	March 11, 2011
2.3.1	744 Processor context information structure definition not clear	March 11, 2011
2.3.1	748 Clarify Standard GUID Text Representation	March 11, 2011
2.3.1	749 Fix Table 10 (Global Variables) With Correct Attributes	March 11, 2011
2.3.1	750 Fix section 27.2.5 "related definitions" re: RSA public key exponent	March 11, 2011
2.3.1	751 Fix USB HC2 erroneous references to IsSlowDevice	March 11, 2011
2.3.1	754 USB timeout parameter mismatch.	April 5, 2011
2.3.1	755 Errata in Legacy MBR table and Legacy MBR GUID	April 5, 2011
2.3.1	759 UEFI Errata - wincerts for rest of hash algorithms	April 5, 2011
2.3.1	760 Suggested changes to 2.3.1 final draft spec	April 5, 2011
2.3.1	761 Table 195. Information for Types of Storage	April 5, 2011
2.3.1	762 DevicePath in the Image Execution Information Table.	April 5, 2011
2.3.1	765 ECR to limit the hash and encryption algorithms used with PKCS certificates	April 5, 2011
2.3.1 A	212 (revisit) final sentence section 28.2.15 missing final words.	April 21, 2011
2.3.1 A	767 The ReadBlocks function for BlockIO and BlockIO2 need synchronization	August 17, 2011
2.3.1 A	770 Remove references to UEFI 2.1 spec	August 17, 2011
2.3.1 A	772 Definition of EFI_IMAGE_SECURITY_DATABAE_GUID incorrect	August 17, 2011
2.3.1 A	773 Clarify the value for opcode EFI_IFR_REFRESH_ID_OP	August 17, 2011
2.3.1 A	774 Define EFI_BLOCK_IO_PROTOCOL_REVISION3	August 17, 2011
2.3.1 A	776 Clarify computation of EFI_VARIABLE_AUTHENTICATION_2 hash value	August 17, 2011
2.3.1 A	777 Specified signature sizes incorrect in Section 27.6.1	August 17, 2011
2.3.1 A	778 EFI_HII_CONFIG_ACCESS_PROTOCOL.CallBack() Errata	August 17, 2011
2.3.1 A	780 Errata in return code descriptions	August 17, 2011
2.3.1 A	785 Allowing more general use of UEFI 2.3.1 Variable time-based authentication	August 17, 2011
2.3.1 A	786 PCI I/O Dual Address Cycle attribute clarification	August 17, 2011
2.3.1 A	788 SasEx entry in Table 86-Device Node Table contains optional Reserved entry that does not exist in device path	August 17, 2011
2.3.1 A	789 Clarify HII opcode definition	August 17, 2011
2.3.1 A	790 Add warning to ReadKeyStrokeEx for partial key press	August 17, 2011
2.3.1 A	793 Inconsistent wording about RemainingDevicePath	August 17, 2011

Unified Extensible Firmware Interface Specification

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.3.1 A	794 Incomplete text describing clearing of Platform Key	August 17, 2011
2.3.1 A	795 Typo in ReadKeyStrokeEx()	August 17, 2011
2.3.1 A	796 Clarify IFR Opcode Summary and Description #1	August 17, 2011
2.3.1 A	797 Clarify IFR Opcode Summary and Description #2	August 17, 2011
2.3.1 A	800 Clarify IFR Opcode Summary and Description #3	August 17, 2011
2.3.1 A	801 Clarify IFR Opcode Summary and Description #4	August 17, 2011
2.3.1 A	803 Fix AcpiExp device node text description.	August 17, 2011
2.3.1 A	804 Clarify constraints and alternatives when enrolling PK, KeK, db or dbx keys	August 17, 2011
2.3.1 A	805 Correct Wrong Palette Information in 28.3.7.2.3 example	August 17, 2011
2.3.1 A	806 Text update to Driver Health Description - clarify role of user interaction	August 17, 2011
2.3.1 A	819 ECR715 was not fully implemented	August 17, 2011
2.3.1 A	820 Driver Health Needs to have Mantis 0000169 implemented	August 17, 2011
2.3.1 A	Minor corrections in toes to tickets 772, 785, 794, 804, also formatting correction for _WIN_CERTIFICATE_UEFI_GUID typedef's parameters	September 7, 2011
2.3.1 B	771 SHA1 and MD5 references	April 10, 2012
2.3.1 B	807 Give specific TPL rules to Stall() boot services	April 10, 2012
2.3.1 B	808 Errata – Boot File URL	April 10, 2012
2.3.1 B	809 Errata – Messaging Device Path Clarification	April 10, 2012
2.3.1 B	812 Errata – DUID-UUID usage	April 10, 2012
2.3.1 B	819 Mantis 715 was not fully implemented	April 10, 2012
2.3.1 B	825 DMTF SM CLP errata	April 10, 2012
2.3.1 B	826 Comments against Mantis 790	April 10, 2012
2.3.1 B	828 Network Driver Options	April 10, 2012
2.3.1 B	836 Structure comment for EFI_IFR_TYPE_VALUE references unknown value type.	April 10, 2012
2.3.1 B	842 Text to explain how the UEFI revision is referred	April 10, 2012
2.3.1 B	845 EFI_SCSI_PASS_THRU_PROTOCOL replacement	April 10, 2012
2.3.1 B	847 When enrolling a PK, the platform shall not require a reboot to leave SetupMode	April 10, 2012
2.3.1 B	848 Clarification of semantics of SecureBoot variable	April 10, 2012
2.3.1 B	849 IFR EFI_IFR_MODAL_TAG_OP is also valid under EFI_IFR_FORM_MAP_OP	April 10, 2012
2.3.1 B	850 Clarification of responsibility for array allocation in EFI_HASH_PROTOCOL	April 10, 2012
2.3.1 B	851 For EFI_IFR_REFRESH opcode, clarify RefreshInterval = 0 means no auto-refresh.	April 10, 2012
2.3.1 B	852 Various EFI_IFR_REFRESH_ID errata.	April 10, 2012
2.3.1 B	853 The EFI_HASH_PROTOCOL.Hash() description needs clarification on padding responsibilities	April 10, 2012

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.3.1 B	855 Clarification of UEFI driver signing/ code definitions	April 10, 2012
2.3.1 B	857 Absolute pointer typo	April 10, 2012
2.3.1 B	858 Superfluous and incorrect image hash description	April 10, 2012
2.3.1 B	861 Globally Defined Variables Errata	April 10, 2012
2.3.1 B	862 User identity typo	April 10, 2012
2.3.1 B	863 Attributes of the Globally Defined Variables	April 10, 2012
2.3.1 B	864 Typo in Question-Level Validation section	April 10, 2012
2.3.1 B	865 Modify Protective MBR BootIndicator definition	April 10, 2012
2.3.1 B	866 PK, KEK, db, dbx relations clarification	April 10, 2012
2.3.1 B	867 Clarify requirement for use of EFI_HASH_SERVICE_BINDING_PROTOCOL	April 10, 2012
2.3.1 B	869 Reference to FIPS 180 in Chapter 27.3 is obsolete and incorrect	April 10, 2012
2.3.1 B	870 Clarify FrameBufferSize definition under EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE struct	April 10, 2012
2.3.1 B	871 Typo in InstallMultipleProtocolInterfaces	April 10, 2012
2.3.1 B	872 Change to SIMPLE_TEXT_INPUT_EX_PROTOCOL.RegisterKeyNotify/ UnregisterKeyNotify	April 10, 2012
2.3.1 B	873 Section 9.3.7 incorrectly assumes that all uses of BBS device paths are non-UEFI	April 10, 2012
2.3.1 B	876 To clarify EDID_OVERRIDE attribute definitions and expected operations	April 10, 2012
2.3.1 B	877 Table checksum update by the ACPI_TABLE_PROTOCOL.InstallAcpiTable	April 10, 2012
2.3.1 B	878 Updated HII "Selected Form" Behaviors to Reflect New Callback Results	April 10, 2012
2.3.1 B	879 Reference to unsupported specification in SCSI Chapter (14.1)	April 10, 2012
2.3.1 B	880 netboot6 clarification/errata	April 10, 2012
2.3.1 B	881 netboot6 - multicast versus unicast	April 10, 2012
2.3.1 B	884 EFI_BOOT_KEY_DATA relies on implementation-defined behavior	April 10, 2012
2.3.1 B	885 Errata in the GPT Table structure comment	April 10, 2012
2.3.1 B	887 union is declared twice in same section	April 10, 2012
2.3.1 B	888 typo in EFI_USB_HC Protocol	April 10, 2012
2.3.1 B	890 Drive Configuration Protocol Phantom.	April 10, 2012
2.3.1 B	891 Component Name Protocol References	April 10, 2012

2.3.1 C	882 Indications Variable - OS/FW feature & capability communication	June 13, 2012
2.3.1 C	907 iSCSI Device Path error	June 13, 2012

Unified Extensible Firmware Interface Specification

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.3.1 C	909 Update to return codes for AllocatePool / AllocatePages	June 13, 2012
2.3.1 C	912 UEFI 2.3.1 Type	June 13, 2012
2.3.1 C	913 Enum definition does not match what our current compilers implement.	June 13, 2012
2.3.1 C	914 Error Descriptor Reset Flag clarification	June 13, 2012
2.3.1 C	915 For x64, Change Floating Point Default Configuration to Double-Extended Precision	June 13, 2012
2.3.1 C	917 UNDI drive does not need to be initialized as runtime driver	June 13, 2012
2.3.1 C	921 Length of IPv6 Device Path is incorrect	June 13, 2012
2.3.1 C	882 Indications Variable - OS/FW feature & capability communication	June 13, 2012
2.3.1 D	924 New Error Code to handle reporting of IPV4 duplicate address detection	April 3, 2013
2.3.1 D	926 UEFI Image Verification clarification	April 3, 2013
2.3.1 D	928 Best Matching Language algorithm	April 3, 2013
2.3.1 D	930 Clarify usage of EFI Variable Varstores in HII	April 3, 2013
2.3.1 D	934 Missing Figures and typos	April 3, 2013
2.3.1 D	935 Clarify chaining requirements with regards to the Platform Key	April 3, 2013
2.3.1 D	938 InstallMultipleProtocolInterface() is missing Status Code Returned values	April 3, 2013
2.3.1 D	941 Add OEM Status Code ranges to EFI Status Code Ranges Table	April 3, 2013
2.3.1 D	942 ExportConfig() description does not make sense	April 3, 2013
2.3.1 D	943 Errata - Proposed updates to required interfaces in chapter 2.6	April 3, 2013
2.3.1 D	944 Errata - Replace RFC reference	April 3, 2013
2.3.1 D	949 PCI IO.GetBarAttributes needs adjustment - - Address Space Granularity field	April 3, 2013
2.3.1 D	950 Indeterminate behavior for attribute modifications may cause security issues	April 3, 2013
2.3.1 D	952 Clarification of requirements to update timestamp associated with authenticated variable	April 3, 2013
2.3.1 D	953 Need text definitions for Device Path Media Type Subtype 6/7	April 3, 2013
2.3.1 D	954 LoadImage Errata	April 3, 2013
2.3.1 D	955 Clearing The Platform Key Errata	April 3, 2013
2.3.1 D	959 InstallAcpiTable() does not say what to do when an attempt is made to install a duplicate table	April 3, 2013
2.3.1 D	960 Typo in netboot6 description	April 3, 2013
2.3.1 D	962 Remove 2.3 table revision number	April 3, 2013
2.3.1 D	965 File IO Async extension	April 3, 2013
2.3.1 D	970 Typo section 28.3.8.3.41 EFI_IFR_MODAL_TAG	April 3, 2013
2.3.1 D	971 typo	April 3, 2013
2.3.1 D	972 ISCSI DHCP6 boot	April 3, 2013
2.3.1 D	973 UNDI Mem_Map() Clarification	April 3, 2013
2.3.1 D	974 UNDI Incorrect CPB function names ECR	April 3, 2013

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.3.1 D	975 UNDI errata to add missing memory type definitions	April 3, 2013
2.3.1 D	976 BrowserCallback text update to description	April 3, 2013
2.3.1 D	977 missing statement	April 3, 2013
2.3.1 D	978 Error Retun Indicates Capsule requires Boot Services	April 3, 2013
2.3.1 D	980 Errata on SNP Media detect	April 3, 2013
2.3.1 D	987 EFI_BLOCK_IO2_PROTOCOL has a copy paste bug describing the Token Parameter	April 3, 2013
2.3.1 D	988 EFI_BLOCK_IO2_PROTOCOL blocks child from stopping while doing non-blocking I/O	April 3, 2013
2.3.1 D	989 Clarify hot-remove responsibility of a Bus Driver	April 3, 2013
2.3.1 D	990 EFI_ATA_PASS_THRU need one clarification if it supports ATAPI device	April 3, 2013
2.3.1 D	994 Spec typos	April 3, 2013
2.3.1 D	995 CSA link change	April 3, 2013
2.3.1 D	996 UEFI 2.0 version number still in the 2.3.1C spec	April 3, 2013
2.3.1 D	1000 Clarification to the IFR_REF4 opcode	April 3, 2013
2.3.1 D	1003 Missing "(" in section 11.7	April 3, 2013
2.3.1 D	1011 Typo regarding Debug Port in UEFI Spec	April 3, 2013
2.3.1 D	1012 Touchup to text of GPT	April 3, 2013
2.3.1 D	1013 HII Errata	April 3, 2013
2.3.1 D	1018 HII Font Errata	April 3, 2013
2.3.1 D	1019 Alignment Requirements Clarification	April 3, 2013
2.3.1 D	1020 Clarify HII variable store definitions.	April 3, 2013
2.3.1 D	1021 ATA_PASS_THRU on ATAPI device handle.	April 3, 2013
2.4	905 Need more granularity in EFI_RESET_TYPE to support platform specific resets	April 25, 2013
2.4	920 Add a variable for indicating out of band key modification	April 25, 2013
2.4	946 Forbid creation of non-spec variables in EFI_GLOBAL_VARIABLE namespace	April 25, 2013
2.4	956 Require network drivers to return EFI_NO_MEDIA	April 25, 2013
2.4	963 Add new device path node NVM Express devices	April 25, 2013
2.4	964 Disk IO 2 Protocol to support Async IO	April 25, 2013
2.4	966 Spec typos	April 25, 2013
2.4	968 HII Forms op-code for displaying a warning message	April 25, 2013
2.4	991 Greater than 256 NICs support on UNDI	April 25, 2013
2.4	992 Adapter Information Protocol (AIP)	April 25, 2013
2.4	993 (original ticket--superseded by 1026)	
2.4	997 Driver Health Protocol error codes	April 25, 2013
2.4	1002 Timestamp Protocol	April 25, 2013
2.4	1007 Create a new Security Technologies section to avoid blurring with Secure Boot	April 25, 2013

Unified Extensible Firmware Interface Specification

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.4	1008 New Random Number Generator / Entropy Protocol	April 25, 2013
2.4	1009 Enable hashes of certificates to be used for revocation, and timestamp support	April 25, 2013
2.4	1015 Interruptible driver diagnostics	April 25, 2013
2.4	1016 AIP Instance - Image Update	April 25, 2013
2.4	1017 AIP Instance - FCOE SAN MAC Address	April 25, 2013
2.4	1022 adapter information protocol for NIC iSCSI and FCoE boot capabilities and current Boot Mode.	April 25, 2013
2.4	1023 Definition of Capsule format to deliver update image to firmware management protocol	April 25, 2013
2.4	1024 Clarification to the NVMe Device Path text descriptions	April 25, 2013
2.4	1026 (supersedes 993) Update to the AArch64 proposed Binding Change	April 25, 2013
2.4	1029 Method for delivery of Capsule on disk; Method for reporting Capsule processing status	April 25, 2013
2.4	1031 NVMe subtype conflict errata	April 25, 2013
2.4	1032 HiiConfigRouting->ExtractConfig Status Codes Errata	May 16, 2013
2.4	1033 HiiConfigAccess->ExtractConfig Status Codes Errata	May 16, 2013
2.4	1036 Comments on April 25 Draft	May 16, 2013
2.4	1037 Add 2.4 to the system table version	May 16, 2013
2.4	1044 Corrections to Mantis 1015, Interruptible driver diagnostics	May 16, 2013
2.4	1045 PCI OpROM Device List changes to section 14.2	June 28, 2013
2.4	1047 Comment on Feb 25th draft - fix alignment issue	May 16, 2013
2.4	1048 Comment against UEFI 2.4 - NVMe related	May 16, 2013
2.4	1049 2.4 Draft April 25 has missing text for ECR 1008	May 16, 2013
2.4	1050 2.4 Draft April 25 has missing text for ECR 1009	May 16, 2013
2.4	1052 UEFI 2.4 Draft April 25th - corrections to ARM sections	May 16, 2013
2.4 A	1035 PCI Option ROM Errata (five figures)	Nov. 6, 2013
2.4 A	1053 Reduce Name space of Capsule Result variable to increase performance	Nov. 6, 2013
2.4 A	1054 Deprecate 6 Hash Algorithms with inconsistent usage	Nov. 6, 2013
2.4 A	1055 Disk IO 2 errata	Nov. 6, 2013
2.4 A	1056 text modification to definition of EFI_FIRMWARE_IMAGE_DESCRIPTOR_VERSION 2	Nov. 6, 2013
2.4 A	1058 Correct mistake in the system table revision	Nov. 6, 2013
2.4 A	1059 Clarification of a return status code of HASH protocol	Nov. 6, 2013
2.4 A	1060 Slight Clarification to FMP Authentication Requirements	Nov. 6, 2013
2.4 A	1061 UEFI 2.4 section 2.6.2 and 2.6.3 don't use protocol hyperlinks consistently	Nov. 6, 2013
2.4 A	1062 EFI_CERT_X509_GUID does not specify the certificate encoding	Nov. 6, 2013
2.4 A	1063 Correction to GPT expression for SizeofPartitionEntry	Nov. 6, 2013
2.4 A	1064 AIP Errata	Nov. 6, 2013

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.4 A	1066 Errata - ISCSI IPV6 Root Path Clarification	Nov. 6, 2013
2.4 A	1073 Add requirement for EFI_USB_IO_PROTOCOL	Nov. 6, 2013
2.4 A	1074 Add clarifications on DMA requirements for PCI_IO	Nov. 6, 2013
2.4 A	1075 Clarifications to Table 88. Device Node Table (Device Node to Text Conversion)	Nov. 6, 2013
2.4 A	1076 typo in UEFI v2.3.1d and v2.4	Nov. 6, 2013
2.4 A	1077 Fix wording in EVT_SIGNAL_EXIT_BOOT_SERVICES	Nov. 6, 2013
2.4 A	1078 Adjust some text for handling EFI_BROWSER_ACTION_CHANGING	Nov. 6, 2013
2.4 A	1079 UEFI 2.4: Remove repetitive "the" (typo)	Nov. 6, 2013
2.4 A	1081 Update Install Table protocol to deal with duplicate tables	Nov. 6, 2013
2.4 A	1082 Mistake in 2.3.5.1 / 2.3.6.2 Handoff State	Nov. 6, 2013
2.4 A	1085 Issues with Interactive password	Nov.14, 2013
2.4 A	1088 Add revision #define to EFI_FILE_PROTOCOL	Nov. 6, 2013
2.4 A	1089 Short-term CPER Memory Section errata	Nov. 14, 2013
2.4B	1014 HII Config Access Protocol Errata	April 3, 2014
2.4 B	1092 Clarification to PCI Option ROM Driver Loading Description	March 27, 2014
2.4 B	1101 Errata – ReinstallProtocolInterface	March 27, 2014
2.4 B	1111 Errors in DisconnectController() return code descriptions	March 27, 2014
2.4 B	1115 Clarification on the usage of XMM/FPU instructions from within a UEFI Runtime Service on an x64 processor	March 27, 2014
2.4 B	1118 Network Performance Enhancements Concerning Volatile Variables	March 27, 2014
2.4 B	1120 Make time stamp handling consistent around all of the networking API's	March 27, 2014
2.4 B	1122 Correct misleading language in the UEFI 2.4a specification about the EFI_ADAPTER_INFORMATION_PROTOCOL.EFI_ADAPTER_INFO_GET_SUPPORTED_TYPES function	March 27, 2014
2.4 B	1124 Adding text description for NVMe device node	March 27, 2014
2.4 B	1127 USB Errata - unnecessary restriction on UEFI interrupt transfer types	March 27, 2014
2.4 B	1128 URI device path node redux--supersedes (defunct) 1119	April 4, 2014
2.4 B	1137 Typographic errors in the 2.4 Errata B draft	April 16, 2014
2.4 B	1146 Typos and broken links	April 17, 2014
2.4 B	1085 Error--added in missing text approved for 2.4A	April 17, 2014
2.4 C	1042 Add Browser Action Request "reconnect"	July 11, 2014
2.4 C	1043 Ability to refresh the entire form [new content]	July 11, 2014
2.4 C	1066 Errata--reference to missing table (90) removed	July 11, 2014
2.4 C	1139 UEFI Errata on the storage security command protocol	July 11, 2014
2.4 C	1140UEFI Errata - image execution info table	July 11, 2014
2.4 C	1141 UEFI errata - ia32/x64 vector register management	July 11, 2014
2.4 C	1147 EFI_USB2_HC_PROTOCOL.AsyncInterruptTransfer() Errata	July 11, 2014
2.4 C	1150 Missing Line Break Character (HII Errata)	July 11, 2014

Unified Extensible Firmware Interface Specification

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.4 C	1162 Typo in ReinstallProtocolInterface() EFI 1.10 Extension section	July 11, 2014
2.4 C	1165 Option rom layout errata	July 11, 2014
2.4 C	1168 MTFTP Errata	July 11, 2014
2.4 C	1169 Errata - volatile networking variable cleanup	July 11, 2014
2.4 C	1170 Errata pxe bc api clarification	July 11, 2014
2.4 C	1172 EfiACPIMemoryNVS definition missing S4	July 11, 2014
2.4 C	1173 EFI_IFR_NUMERIC Errata	July 11, 2014
2.4 C	1174 errata - Error in EFI_IFR_PASSWORD logic flowchart	January, 2015
2.4 C	1182 Errata - UEFI URI Device path issue	January, 2015
2.4 C	1184 errata - snp mode clarification	January, 2015
2.4 C	1185 errata - tcp api	January, 2015
2.4 C	1186 AArch64 binding clarifications and errata	January, 2015
2.4 C	1192 Cleanup GUID formatting issues	January, 2015
2.4 C	1194 Add EFI_IFR_FLAG_RECONNECT_REQUIRED	January, 2015
2.4 C	1198 EFI_ATA_PASS_THRU_PROTOCOL clarification	January, 2015
2.4 C	1200 Universal Flash Storage (UFS) Device Path	January, 2015
2.4 C	1205 Errata for Hii Set item	January, 2015
2.4 C	1209 Errata - UEFI networking API chapter 2.6 requirements	January, 2015
2.4 C	1211 EFI_LOAD_OPTION Definition	January, 2015
2.4 C	1244 sections of the spec misarranged	January, 2015
2.4 C	1257 Correct the typedef definitions for EFI_BOOT_SERVICES/ EFI_RUNTIME_SERVICES	January, 2015
2.4 C	1287 Errata: EFI Driver Supported EFI Version not matching the spec revision	January, 2015
2.4 C	1308 Fix typo's found in the final/published UEFI 2.4 Errata B spec	January, 2015
2.5	1071 New EFI_HASH2_PROTOCOL	February, 2015
2.5	1090 ESRT: EFI System Resource Table and component firmware updates	February, 2015
2.5	1091 Clarification of handle to host FMP	February, 2015
2.5	1103 Longer term New CPER Memory Section	February, 2015
2.5	1109 Smart Card Reader	February, 2015
2.5	1121 IPV6 support from UNDI	February, 2015
2.5	1147--REDACT	February, 2015
2.5	1163 Inline Cryptographic Interface Protocol proposal	February, 2015
2.5	1166 hash 2 protocol errata	February, 2015
2.5	1158 errata - boot manager clarification	February, 2015
2.5	1159 Proposal for System Prep Applications	February, 2015
2.5	1167 Persistent Memory Type support	February, 2015
2.5	1174 errata - Error in EFI_IFR_PASSWORD logic flowchart	February, 2015

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.5	1183 New Protocol with 2 Function for PKCS7 Signature Verification Services	February, 2015
2.5	1186 AArch64 binding clarifications and errata	February, 2015
2.5	1191 Add new SMBIOS3_TABLE_GUID in EFI_CONFIGURATION_TABLE	February, 2015
2.5	1199 Add NVM Express Pass Thru Protocol	February, 2015
2.5	1201 Exposing Memory Redundancy to OSPM	February, 2015
2.5	1204 new UEFI USB Function I/O Protocol addition to the UEFI spec	February, 2015
2.5	1212 UEFI.Next feature - HTTP API	February, 2015
2.5	1213 UEFI.Next feature - HTTP helper API	February, 2015
2.5	1214 UEFI.Next feature - HTTP Boot	February, 2015
2.5	1215 UEFI.Next feature - DNS version 4	February, 2015
2.5	1216 UEFI.next feature - DNS version 6	February, 2015
2.5	1217 UEFI.Next feature - WIFI support	February, 2015
2.5	1218 UEFI.Next feature - EAP2 Protocol	February, 2015
2.5	1219 UEFI.Next Feature - UEFI TLS API	February, 2015
2.5	1220 UEFI.Next feature - Bluetooth	February, 2015
2.5	1221 UEFI.Next feature - REST Protocol	February, 2015
2.5	1222 UEFI.Next feature - BMC/Service Processor Device Path	February, 2015
2.5	1223 UEFI.Next networking features - chapter 2.6 requirements	February, 2015
2.5	1224 UEFI.Next - Adding support for No executable data areas	February, 2015
2.5	1227 UEFI.Next feature - Platform recovery	February, 2015
2.5	1234 UEFI.Next feature - Smart card edge protocol	February, 2015
2.5	1244 sections of the spec mis-arranged	February, 2015
2.5	1251 EFI_REGULAR_EXPRESSION_PROTOCOL and EFI_IFR_MATCH2 HII op-code	February, 2015
2.5	1254 SD Device Path	February, 2015
2.5	1255 UFS Device Path Node Length	February, 2015
2.5	1257 Correct the typedef definitions for EFI_BOOT_SERVICES/EFI_RUNTIME_SERVICES--Reiterate	February, 2015
2.5	1263 Customized Deployment of Secure Boot	February, 2015
2.5	1266 UEFI.Next Feature - IP_CONFIG2 Protocol	February, 2015
2.5	1268 RAM Disk UEFI Device Path Node	February, 2015
2.5	1269 Configuration Routing Protocol and Configuration String Updates	February, 2015
2.5	1287 Errata: EFI Driver Supported EFI Version not matching the spec revision	February, 2015
2.5	1288 The Macro definition conflict in EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetAttribute() in UEFI 2.4 B	February, 2015
2.5	1303 Update the UEFI version to reflect new revision	February, 2015
2.5	1304 Add IMAGE_UPDATABLE_VALID_WITH_VENDOR_CODE to FMP Check image	February, 2015

Unified Extensible Firmware Interface Specification

Revision	Revision History (numbers = Mantis ticket numbers)	Date
2.5	1308 Fix typo's found in the final/published UEFI 2.4 Errata B spec	February, 2015
2.5	1309 Disallow EFI_VARIABLE_AUTHENTICATION from Secure Boot Policy Variables	April, 2015
2.5	1339 Errata in section 7.2.3.2 Hardware Error Record Variables	April, 2015
2.5	1341 DNS4 - friendly amendment to be reviewed by USWG	April, 2015

Introduction

This *Unified Extensible Firmware Interface* (hereafter known as UEFI) *Specification* describes an interface between the operating system (OS) and the platform firmware. UEFI was preceded by the *Extensible Firmware Interface Specification 1.10* (EFI). As a result, some code and certain protocol names retain the EFI designation. Unless otherwise noted, EFI designations in this specification may be assumed to be part of UEFI.

The interface is in the form of data tables that contain platform-related information, and boot and runtime service calls that are available to the OS loader and the OS. Together, these provide a standard environment for booting an OS. This specification is designed as a pure interface specification. As such, the specification defines the set of interfaces and structures that platform firmware must implement. Similarly, the specification defines the set of interfaces and structures that the OS may use in booting. How either the firmware developer chooses to implement the required elements or the OS developer chooses to make use of those interfaces and structures is an implementation decision left for the developer.

The intent of this specification is to define a way for the OS and platform firmware to communicate only information necessary to support the OS boot process. This is accomplished through a formal and complete abstract specification of the software-visible interface presented to the OS by the platform and firmware.

Using this formal definition, a shrink-wrap OS intended to run on platforms compatible with supported processor specifications will be able to boot on a variety of system designs without further platform or OS customization. The definition will also allow for platform innovation to introduce new features and functionality that enhance platform capability without requiring new code to be written in the OS boot sequence.

Furthermore, an abstract specification opens a route to replace legacy devices and firmware code over time. New device types and associated code can provide equivalent functionality through the same defined abstract interface, again without impact on the OS boot support code.

The specification is applicable to a full range of hardware platforms from mobile systems to servers. The specification provides a core set of services along with a selection of protocol interfaces. The selection of protocol interfaces can evolve over time to be optimized for various platform market segments. At the same time, the specification allows maximum extensibility and customization abilities for OEMs to allow differentiation. In this, the purpose of UEFI is to define an evolutionary path from the traditional “PC-AT”-style boot world into a legacy-API free environment.

1.1 UEFI Driver Model Extensions

Access to boot devices is provided through a set of protocol interfaces. One purpose of the UEFI *Driver Model* is to provide a replacement for “PC-AT”-style option ROMs. It is important to point out that drivers written to the UEFI *Driver Model* are designed to access boot devices in the preboot environment. They are not designed to replace the high-performance, OS-specific drivers.

The *UEFI Driver Model* is designed to support the execution of modular pieces of code, also known as drivers, that run in the preboot environment. These drivers may manage or control hardware buses and devices on the platform, or they may provide some software-derived, platform-specific service.

The *UEFI Driver Model* also contains information required by UEFI driver writers to design and implement any combination of bus drivers and device drivers that a platform might need to boot a UEFI-compliant OS.

The *UEFI Driver Model* is designed to be generic and can be adapted to any type of bus or device. The *UEFI Specification* describes how to write PCI bus drivers, PCI device drivers, USB bus drivers, USB device drivers, and SCSI drivers. Additional details are provided that allow UEFI drivers to be stored in PCI option ROMs, while maintaining compatibility with legacy option ROM images.

One of the design goals in the *UEFI Specification* is keeping the driver images as small as possible. However, if a driver is required to support multiple processor architectures, a driver object file would also be required to be shipped for each supported processor architecture. To address this space issue, this specification also defines the *EFI Byte Code Virtual Machine*. A UEFI driver can be compiled into a single EFI Byte Code object file. UEFI Specification-complaint firmware must contain an EFI Byte Code interpreter. This allows a single EFI Byte Code object file that supports multiple processor architectures to be shipped. Another space saving technique is the use of compression. This specification defines compression and decompression algorithms that may be used to reduce the size of UEFI Drivers, and thus reduce the overhead when UEFI Drivers are stored in ROM devices.

The information contained in the *UEFI Specification* can be used by OSVs, IHVs, OEMs, and firmware vendors to design and implement firmware conforming to this specification, drivers that produce standard protocol interfaces, and operating system loaders that can be used to boot UEFI-compliant operating systems.

1.2 Overview

The UEFI Specification is organized as listed in [Table 1](#).

Table 1. Organization of the UEFI Specification

Section/Appendix	Description
1. Introduction	Introduces the UEFI Specification and topics related to using the specification.
2. Overview	Describes the major components of UEFI, including the boot manager, firmware core, calling conventions, protocols, and requirements.
3. Boot Manager	Describes the boot manager, which is used to load drivers and applications written to this specification.
4. EFI System Table	Describes the EFI System Table that is passed to every compliant driver and application.
5. GUID Partition Table (GPT) Format	Defines a new partitioning scheme that must be supported by firmware conforming to this specification.

Section/Appendix	Description
6. Services — Boot Services	Contains the definitions of the fundamental services that are present in a UEFI-compliant system before an OS is booted.
7. Services — Runtime Services	Contains definitions for the fundamental services that are present in a compliant system before and after an OS is booted.
8. Protocols — EFI Loaded Image	Defines the EFI Loaded Image Protocol that describes a UEFI Image that has been loaded into memory.
9 Protocols — Device Path Protocol	Defines the device path protocol and provides the information needed to construct and manage device paths in the UEFI environment.
10. Protocols — UEFI Driver Model	Describes a generic driver model for UEFI. This includes the set of services and protocols that apply to every bus and device type, including the Driver Binding Protocol, the Platform Driver Override Protocol, the Bus Specific Driver Override Protocol, the Driver Diagnostics Protocol, the Driver Configuration Protocol, and the Component Name Protocol.
11. Protocols — Console Support	Defines the Console I/O protocols, which handle input and output of text-based information intended for the system user while executing in the boot services environment. These protocols include the Simple Input Protocol, the Simple Text Output Protocol, the Graphics Output Protocol, the Simple Pointer Protocol, and the Serial I/O Protocol.
12. Protocols—Media Access	Defines the Load File protocol, file system format and media formats for handling removable media.
13. Protocols — PCI Bus Support	Defines PCI Bus Drivers, PCI Device Drivers, and PCI Option ROM layouts. The protocols described include the PCI Root Bridge I/O Protocol and the PCI I/O Protocol.
14. Protocols — SCSI Driver Models and Bus Support	Defines the SCSI I/O Protocol and the Extended SCSI Pass Thru Protocol that is used to abstract access to a SCSI channel that is produced by a SCSI host controller.
15. Protocols —iSCSI Boot	The iSCSI protocol defines a transport for SCSI data over TCP/IP.
16. Protocols — USB Support	Defines USB Bus Drivers and USB Device Drivers. The protocols described include the USB2 Host Controller Protocol and the USB I/O Protocol.
17. Protocols — Debugger Support	An optional set of protocols that provide the services required to implement a source-level debugger for the UEFI environment. The EFI Debug Port Protocol provides services to communicate with a remote debug host. The Debug Support Protocol provides services to hook processor exceptions, save the processor context, and restore the processor context. These protocols can be used in the implementation of a debug agent on the target system that interacts with the remote debug host.

Unified Extensible Firmware Interface Specification

Section/Appendix	Description
18. Protocols — Compression Algorithm Specification	Describes in detail the compression/decompression algorithm, as well as the EFI Decompress Protocol. The EFI Decompress Protocol provides a standard decompression interface for use at boot time. The EFI Decompress Protocol is used by a PCI Bus Driver to decompress UEFI drivers stored in PCI Option ROMs.
19. Protocols — ACPI Protocols	Defines a protocol that may be used to install or remove an ACPI table from a platform.
20. EFI Byte Code Virtual Machine	Defines the EFI Byte Code virtual processor and its instruction set. It also defines how EBC object files are loaded into memory, and the mechanism for transitioning from native code to EBC code and back to native code. The information in this document is sufficient to implement an EFI Byte Code interpreter, an EFI Byte Code compiler, and an EFI Byte Code linker.
21. Network Protocols—SNP, PXE, and BIS	Defines the protocols that provide access to network devices while executing in the UEFI boot services environment. These protocols include the Simple Network Protocol, the PXE Base Code Protocol, and the Boot Integrity services (BIS) Protocol.
22. Network Protocols—Managed Network	Defines the EFI Managed Network Protocol, which provides raw (unformatted) asynchronous network packet I/O services and Managed Network Service Binding Protocol, which is used to locate communication devices that are supported by an MNP driver.
23. Network Protocols—VLAN and EAP	Defines a protocol is to provide a manageability interface for VLAN configurations.
24. Network Protocols—TCP, IP, IPsec, FTP and Configuration	Defines the EFI TCPv4 (Transmission Control Protocol version 4) Protocol and the EFI IPv4 (Internet Protocol version 4) Protocol interface.
25. Network Protocols—ARP and DHCP	Defines the EFI Address Resolution Protocol (ARP) Protocol interface and the EFI DHCPv4 Protocol.
26. Network Protocols—UDPv4 and MTFTPv4	Defines the EFI UDPv4 (User Datagram Protocol version 4) Protocol that interfaces over the EFI IPv4 Protocol and defines the EFI MTFTPv4 Protocol interface that is built on the EFI UDPv4 Protocol.
27. Secure Boot and Driver Signing	Describes Secure Boot and a means of generating a digital signature for UEFI.
28. Human Interface Infrastructure Overview	Defines the core code and services that are required for an implementation of the Human Interface Infrastructure (HII), including basic mechanisms for managing user input and code definitions for related protocols.
29. HII Protocols	Provides code definitions for the HII-related protocols, functions, and type definitions, including management of font, strings, images and databases.
30. HII Configuration Processing and Browser Protocol	Describes the data and APIs used to manage the system's configuration: the actual data that describes the knobs and settings.

Section/Appendix	Description
31. User Identification	Describes services which describe the current user of the platform.
32. Firmware Management Protocol	Provides an abstraction for devices to provide firmware management support.
33. Secure Technologies	Describes the protocols for utilizing security technologies including cryptographic hashing and key management.
34. Protocols - Timestamp Protocol	Provides a platform independent interface for retrieving a high resolution timestamp counter.
A. GUID and Time Formats	Explains the GUID (Guaranteed Unique Identifier) format.
B. Console	Describes the requirements for a basic text-based console required by EFI-conformant systems to provide communication capabilities.
C. Device Path Examples	Examples of use of the data structures that define various hardware devices to the boot services.
D. Status Codes	Lists success, error, and warning codes returned by UEFI interfaces.
E. Universal Network Driver Interfaces	Defines the 32/64-bit hardware and software Universal Network Driver Interfaces (UNDIs).
F. Using the Simple Pointer Protocol	Provides the suggested usage of the Simple Pointer Protocol.
G. Using the EFI Extended SCSI Pass Thru Protocol	Provides an example of how the SCSI Pass Thru Protocol can be used.
H. Compression Source Code	The C source code to an implementation of the Compression Algorithm.
I. Decompression Source Code	The C source code to an implementation of the EFI Decompression Algorithm.
J. EFI Byte Code Virtual Machine Opcode Lists	A summary of the opcodes in the instruction set of the EFI Byte Code Virtual Machine.
K. Alphabetic Function List	Lists all UEFI interface functions alphabetically.
L. EFI 1.10 Protocol Changes and Deprecation Lists	Lists the Protocol, GUID, and revision identifier name changes and the deprecated protocols compared to the <i>EFI Specification 1.10</i> .
M. Formats—Language Codes and Language Code Arrays	Lists the formats for language codes and language code arrays.
N. Common Platform Error Record	Describes the common platform error record format for representing platform hardware errors.
O. UEFI ACPI Table	Defines the UEFI ACPI table format.
P. Hardware Error Record Persistence Usage	Defines Hardware Error Record Persistence usage.
Q. References	Lists all necessary or useful specifications, web sites, and other documentation that is referenced in this UEFI specification.
R. Glossary	Briefly describes terms defined or referenced by this specification.
Index	Provides an index to the key terms and concepts in the specification.

1.3 Goals

The “PC-AT” boot environment presents significant challenges to innovation within the industry. Each new platform capability or hardware innovation requires firmware developers to craft increasingly complex solutions, and often requires OS developers to make changes to their boot code before customers can benefit from the innovation. This can be a time-consuming process requiring a significant investment of resources.

The primary goal of the UEFI specification is to define an alternative boot environment that can alleviate some of these considerations. In this goal, the specification is similar to other existing boot specifications. The main properties of this specification can be summarized by these attributes:

- ***Coherent, scalable platform environment.*** The specification defines a complete solution for the firmware to describe all platform features and surface platform capabilities to the OS during the boot process. The definitions are rich enough to cover a range of contemporary processor designs.
- ***Abstraction of the OS from the firmware.*** The specification defines interfaces to platform capabilities. Through the use of abstract interfaces, the specification allows the OS loader to be constructed with far less knowledge of the platform and firmware that underlie those interfaces. The interfaces represent a well-defined and stable boundary between the underlying platform and firmware implementation and the OS loader. Such a boundary allows the underlying firmware and the OS loader to change provided both limit their interactions to the defined interfaces.
- ***Reasonable device abstraction free of legacy interfaces.*** “PC-AT” BIOS interfaces require the OS loader to have specific knowledge of the workings of certain hardware devices. This specification provides OS loader developers with something different: abstract interfaces that make it possible to build code that works on a range of underlying hardware devices without having explicit knowledge of the specifics for each device in the range.
- ***Abstraction of Option ROMs from the firmware.*** This specification defines interfaces to platform capabilities including standard bus types such as PCI, USB, and SCSI. The list of supported bus types may grow over time, so a mechanism to extend to future bus types is included. These defined interfaces, and the ability to extend to future bus types, are components of the UEFI *Driver Model*. One purpose of the UEFI *Driver Model* is to solve a wide range of issues that are present in existing “PC-AT” option ROMs. Like OS loaders, drivers use the abstract interfaces so device drivers and bus drivers can be constructed with far less knowledge of the platform and firmware that underlie those interfaces.
- ***Architecturally shareable system partition.*** Initiatives to expand platform capabilities and add new devices often require software support. In many cases, when these platform innovations are activated before the OS takes control of the platform, they must be supported by code that is specific to the platform rather than to the customer’s choice of OS. The traditional approach to this problem has been to embed code in the platform during manufacturing (for example, in flash memory devices). Demand for such persistent storage is increasing at a rapid rate. This specification defines persistent store on large mass storage media types for use by platform support code extensions to supplement the traditional approach. The definition of how this works is made clear in the specification to ensure that firmware developers, OEMs, operating system vendors, and perhaps even third parties can share the space safely while adding to platform capability.

Defining a boot environment that delivers these attributes could be accomplished in many ways. Indeed, several alternatives, perhaps viable from an academic point of view, already existed at the time this specification was written. These alternatives, however, typically presented high barriers to entry given the current infrastructure capabilities surrounding supported processor platforms. This specification is intended to deliver the attributes listed above, while also recognizing the unique needs of an industry that has considerable investment in compatibility and a large installed base of systems that cannot be abandoned summarily. These needs drive the requirements for the additional attributes embodied in this specification:

- ***Evolutionary, not revolutionary.*** The interfaces and structures in the specification are designed to reduce the burden of an initial implementation as much as possible. While care has been taken to ensure that appropriate abstractions are maintained in the interfaces themselves, the design also ensures that reuse of BIOS code to implement the interfaces is possible with a minimum of additional coding effort. In other words, on PC-AT platforms the specification can be implemented initially as a thin interface layer over an underlying implementation based on existing code. At the same time, introduction of the abstract interfaces provides for migration away from legacy code in the future. Once the abstraction is established as the means for the firmware and OS loader to interact during boot, developers are free to replace legacy code underneath the abstract interfaces at leisure. A similar migration for hardware legacy is also possible. Since the abstractions hide the specifics of devices, it is possible to remove underlying hardware, and replace it with new hardware that provides improved functionality, reduced cost, or both. Clearly this requires that new platform firmware be written to support the device and present it to the OS loader via the abstract interfaces. However, without the interface abstraction, removal of the legacy device might not be possible at all.
- ***Compatibility by design.*** The design of the system partition structures also preserves all the structures that are currently used in the “PC-AT” boot environment. Thus, it is a simple matter to construct a single system that is capable of booting a legacy OS or an EFI-aware OS from the same disk.
- ***Simplifies addition of OS-neutral platform value-add.*** The specification defines an open, extensible interface that lends itself to the creation of platform “drivers.” These may be analogous to OS drivers, providing support for new device types during the boot process, or they may be used to implement enhanced platform capabilities, such as fault tolerance or security. Furthermore, this ability to extend platform capability is designed into the specification from the outset. This is intended to help developers avoid many of the frustrations inherent in trying to squeeze new code into the traditional BIOS environment. As a result of the inclusion of interfaces to add new protocols, OEMs or firmware developers have an infrastructure to add capability to the platform in a modular way. Such drivers may potentially be implemented using high-level coding languages because of the calling conventions and environment defined in the specification. This in turn may help to reduce the difficulty and cost of innovation. The option of a system partition provides an alternative to nonvolatile memory storage for such extensions.
- ***Built on existing investment.*** Where possible, the specification avoids redefining interfaces and structures in areas where existing industry specifications provide adequate coverage. For example, the ACPI specification provides the OS with all the information necessary to discover and configure platform resources. Again, this philosophical choice for the design of the specification is intended to keep barriers to its adoption as low as possible.

1.4 Target Audience

This document is intended for the following readers:

- IHVs and OEMs who will be implementing UEFI drivers.
- OEMs who will be creating supported processor platforms intended to boot shrink-wrap operating systems.
- BIOS developers, either those who create general-purpose BIOS and other firmware products or those who modify these products for use in supported processor-based products.
- Operating system developers who will be adapting their shrink-wrap operating system products to run on supported processor-based platforms.

1.5 UEFI Design Overview

The design of UEFI is based on the following fundamental elements:

- ***Reuse of existing table-based interfaces.*** In order to preserve investment in existing infrastructure support code, both in the OS and firmware, a number of existing specifications that are commonly implemented on platforms compatible with supported processor specifications must be implemented on platforms wishing to comply with the UEFI specification. (For additional information, see [Appendix Q](#).)
- ***System partition.*** The System partition defines a partition and file system that are designed to allow safe sharing between multiple vendors, and for different purposes. The ability to include a separate, sharable system partition presents an opportunity to increase platform value-add without significantly growing the need for nonvolatile platform memory.
- ***Boot services.*** Boot services provide interfaces for devices and system functionality that can be used during boot time. Device access is abstracted through “handles” and “protocols.” This facilitates reuse of investment in existing BIOS code by keeping underlying implementation requirements out of the specification without burdening the consumer accessing the device.
- ***Runtime services.*** A minimal set of runtime services is presented to ensure appropriate abstraction of base platform hardware resources that may be needed by the OS during its normal operations.

[Figure 1](#) shows the principal components of UEFI and their relationship to platform hardware and OS software.

Figure 1. UEFI Conceptual Overview

[Figure 1](#) illustrates the interactions of the various components of an UEFI specification-compliant system that are used to accomplish platform and OS boot.

The platform firmware is able to retrieve the OS loader image from the System Partition. The specification provides for a variety of mass storage device types including disk, CD-ROM, and DVD as well as remote boot via a network. Through the extensible protocol interfaces, it is possible to add other boot media types, although these may require OS loader modifications if they require use of protocols other than those defined in this document.

Once started, the OS loader continues to boot the complete operating system. To do so, it may use the EFI boot services and interfaces defined by this or other required specifications to survey, comprehend, and initialize the various platform components and the OS software that manages them. EFI runtime services are also available to the OS loader during the boot phase.

1.6 UEFI Driver Model

This section describes the goals of a driver model for firmware conforming to this specification. The goal is for this driver model to provide a mechanism for implementing bus drivers and device drivers for all types of buses and devices. At the time of writing, supported bus types include PCI, USB, and so on.

As hardware architectures continue to evolve, the number and types of buses present in platforms are increasing. This trend is especially true in high-end servers. However, a more diverse set of bus types is being designed into desktop and mobile systems and even some embedded systems. This increasing complexity means that a simple method for describing and managing all the buses and devices in a platform is required in the preboot environment. The *UEFI Driver Model* provides this simple method in the form of protocols services and boot services.

1.6.1 UEFI Driver Model Goals

The UEFI *Driver Model* has the following goals:

- **Compatible** – Drivers conforming to this specification must maintain compatibility with the *EFI 1.10 Specification* and the *UEFI Specification*. This means that the UEFI *Driver Model* takes advantage of the extensibility mechanisms in the *UEFI 2.0 Specification* to add the required functionality.
- **Simple** – Drivers that conform to this specification must be simple to implement and simple to maintain. The UEFI *Driver Model* must allow a driver writer to concentrate on the specific device for which the driver is being developed. A driver should not be concerned with platform policy or platform management issues. These considerations should be left to the system firmware.
- **Scalable** – The UEFI *Driver Model* must be able to adapt to all types of platforms. These platforms include embedded systems, mobile, and desktop systems, as well as workstations and servers.
- **Flexible** – The UEFI *Driver Model* must support the ability to enumerate all the devices, or to enumerate only those devices required to boot the required OS. The minimum device enumeration provides support for more rapid boot capability, and the full device enumeration provides the ability to perform OS installations, system maintenance, or system diagnostics on any boot device present in the system.
- **Extensible** – The UEFI *Driver Model* must be able to extend to future bus types as they are defined.
- **Portable** – Drivers written to the UEFI *Driver Model* must be portable between platforms and between supported processor architectures.
- **Interoperable** – Drivers must coexist with other drivers and system firmware and must do so without generating resource conflicts.
- **Describe complex bus hierarchies** – The UEFI *Driver Model* must be able to describe a variety of bus topologies from very simple single bus platforms to very complex platforms containing many buses of various types.
- **Small driver footprint** – The size of executables produced by the UEFI *Driver Model* must be minimized to reduce the overall platform cost. While flexibility and extensibility are goals, the additional overhead required to support these must be kept to a minimum to prevent the size of firmware components from becoming unmanageable.
- **Address legacy option rom issues** – The UEFI *Driver Model* must directly address and solve the constraints and limitations of legacy option ROMs. Specifically, it must be possible to build add-in cards that support both UEFI drivers and legacy option ROMs, where such cards can execute in both legacy BIOS systems and UEFI-conforming platforms, without modifications to the code carried on the card. The solution must provide an evolutionary path to migrate from legacy option ROMs driver to UEFI drivers.

1.6.2 Legacy Option ROM Issues

This idea of supporting a driver model came from feedback on the *UEFI Specification* that provided a clear, market-driven requirement for an alternative to the legacy option ROM (sometimes also

referred to as an expansion ROM). The perception is that the advent of the *UEFI Specification* represents a chance to escape the limitations implicit in the construction and operation of legacy option ROM images by replacing them with an alternative mechanism that works within the framework of the *UEFI Specification*.

1.7 Migration Requirements

Migration requirements cover the transition period from initial implementation of this specification to a future time when all platforms and operating systems implement to this specification. During this period, two major compatibility considerations are important:

- The ability to continue booting legacy operating systems;
- The ability to implement UEFI on existing platforms by reusing as much existing firmware code to keep development resource and time requirements to a minimum.

1.7.1 Legacy Operating System Support

The UEFI specification represents the preferred means for a shrink-wrap OS and firmware to communicate during the boot process. However, choosing to make a platform that complies with this specification in no way precludes a platform from also supporting existing legacy OS binaries that have no knowledge of the UEFI specification.

The UEFI specification does not restrict a platform designer who chooses to support both the UEFI specification and a more traditional “PC-AT” boot infrastructure. If such a legacy infrastructure is to be implemented, it should be developed in accordance with existing industry practice that is defined outside the scope of this specification. The choice of legacy operating systems that are supported on any given platform is left to the manufacturer of that platform.

1.7.2 Supporting the UEFI Specification on a Legacy Platform

The UEFI specification has been carefully designed to allow for existing systems to be extended to support it with a minimum of development effort. In particular, the abstract structures and services defined in the UEFI specification can all be supported on legacy platforms.

For example, to accomplish such support on an existing and supported 32-bit-based platform that uses traditional BIOS to support operating system boot, an additional layer of firmware code would need to be provided. This extra code would be required to translate existing interfaces for services and devices into support for the abstractions defined in this specification.

1.8 Conventions Used in this Document

This document uses typographic and illustrative conventions described below.

1.8.1 Data Structure Descriptions

Supported processors are “little endian” machines. This distinction means that the low-order byte of a multibyte data item in memory is at the lowest address, while the high-order byte is at the highest address. Some supported 64-bit processors may be configured for both “little endian” and “big

endian” operation. All implementations designed to conform to this specification use “little endian” operation.

In some memory layout descriptions, certain fields are marked *reserved*. Software must initialize such fields to zero and ignore them when read. On an update operation, software must preserve any reserved field.

1.8.2 Protocol Descriptions

A protocol description generally has the following format:

Protocol Name:	The formal name of the protocol interface.
Summary:	A brief description of the protocol interface.
GUID:	The 128-bit Globally Unique Identifier (GUID) for the protocol interface.
Protocol Interface Structure:	A “C-style” data structure definition containing the procedures and data fields produced by this protocol interface.
Parameters:	A brief description of each field in the protocol interface structure.
Description:	A description of the functionality provided by the interface, including any limitations and caveats of which the caller should be aware.
Related Definitions:	The type declarations and constants that are used in the protocol interface structure or any of its procedures.

1.8.3 Procedure Descriptions

A procedure description generally has the following format:

ProcedureName():	The formal name of the procedure.
Summary:	A brief description of the procedure.
Prototype:	A “C-style” procedure header defining the calling sequence.
Parameters:	A brief description of each field in the procedure prototype.
Description:	A description of the functionality provided by the interface, including any limitations and caveats of which the caller should be aware.
Related Definitions:	The type declarations and constants that are used only by this procedure.
Status Codes Returned:	A description of any codes returned by the interface. The procedure is required to implement any status codes listed in this

table. Additional error codes may be returned, but they will not be tested by standard compliance tests, and any software that uses the procedure cannot depend on any of the extended error codes that an implementation may provide.

1.8.4 Instruction Descriptions

An instruction description for EBC instructions generally has the following format:

InstructionName	The formal name of the instruction.
Syntax:	A brief description of the instruction.
Description:	A description of the functionality provided by the instruction accompanied by a table that details the instruction encoding.
Operation:	Details the operations performed on operands.
Behaviors and Restrictions:	An item-by-item description of the behavior of each operand involved in the instruction and any restrictions that apply to the operands or the instruction.

1.8.5 Pseudo-Code Conventions

Pseudo code is presented to describe algorithms in a more concise form. None of the algorithms in this document are intended to be compiled directly. The code is presented at a level corresponding to the surrounding text.

In describing variables, a *list* is an unordered collection of homogeneous objects. A *queue* is an ordered list of homogeneous objects. Unless otherwise noted, the ordering is assumed to be FIFO.

Pseudo code is presented in a C-like format, using C conventions where appropriate. The coding style, particularly the indentation style, is used for readability and does not necessarily comply with an implementation of the *UEFI Specification*.

1.8.6 Typographic Conventions

This document uses the typographic and illustrative conventions described below:

Plain text	The normal text typeface is used for the vast majority of the descriptive text in a specification.
<u>Plain text (blue)</u>	Any <u>plain text</u> that is underlined and in blue indicates an active link to the cross-reference. Click on the word to follow the hyperlink.
Bold	In text, a Bold typeface identifies a processor register name. In other instances, a Bold typeface can be used as a running head within a paragraph.
<i>Italic</i>	In text, an <i>Italic</i> typeface can be used as emphasis to introduce a new term or to indicate a manual or specification name.

BOLD Monospace Computer code, example code segments, and all prototype code segments use a **BOLD Monospace** typeface with a dark red color. These code listings normally appear in one or more separate paragraphs, though words or segments can also be embedded in a normal text paragraph.

Bold Monospace Words in a **Bold Monospace** typeface that is underlined and in blue indicate an active hyperlink to the code definition for that function or type definition. Click on the word to follow the hyperlink.

Note: *Due to management and file size considerations, only the first occurrence of the reference on each page is an active link. Subsequent references on the same page will not be actively linked to the definition and will use the standard, nonunderlined **BOLD Monospace** typeface. Find the first instance of the name (in the underlined **BOLD Monospace** typeface) on the page and click on the word to jump to the function or type definition.*

Italic Monospace In code or in text, words in *Italic Monospace* indicate placeholder names for variable information that must be supplied (i.e., arguments).

1.8.7 Number formats

A binary number is represented in this standard by any sequence of digits consisting of only the Western-Arab numerals 0 and 1 immediately followed by a lower-case b (e.g., 0101b).

Underscores or spaces may be included between characters in binary number representations to increase readability or delineate field boundaries (e.g., 0 0101 1010b or 0_0101_1010b).

1.8.7.1 Hexadecimal

A hexadecimal number is represented in this standard by 0x preceding any sequence of digits consisting of only the Western-Arab numerals 0 through 9 and/or the upper-case English letters A through F (e.g., 0xFA23).

Underscores or spaces may be included between characters in hexadecimal number representations to increase readability or delineate field boundaries (e.g., 0xB FD8C FA23 or 0xB_FD8C_FA23).

1.8.7.2 Decimal

A decimal number is represented in this standard by any sequence of digits consisting of only the Arabic numerals 0 through 9 not immediately followed by a lower-case b or lower-case h (e.g., 25).

This standard uses the following conventions for representing decimal numbers:

- the decimal separator (i.e., separating the integer and fractional portions of the number) is a period;
- the thousands separator (i.e., separating groups of three digits in a portion of the number) is a comma;
- the thousands separator is used in the integer portion and is not used in the fraction portion of a number.

1.8.8 Binary prefixes

This standard uses the prefixes defined in the International System of Units (SI) for values that are powers of ten. See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “SI Binary Prefixes”.

Table 2. SI prefixes

10^3	1,000	kilo	K
10^6	1,000,000	mega	M
10^9	1,000,000,000	giga	G

This standard uses the binary prefixes defined in ISO/IEC 80000-13 *Quantities and units -- Part 13: Information science and technology* and IEEE 1514 *Standard for Prefixes for Binary Multiples* for values that are powers of two.

Table 3. Binary prefixes

Factor	Factor	Name	Symbol
2^{10}	1,024	kibi	Ki
2^{20}	1,048,576	mebi	Mi
2^{30}	1,073,741,824	gibi	Gi

For example, 4 KB means 4,000 bytes and 4 KiB means 4,096 bytes.

2 Overview

UEFI allows the extension of platform firmware by loading UEFI driver and UEFI application images. When UEFI drivers and UEFI applications are loaded they have access to all UEFI-defined runtime and boot services. See [Figure 2](#).

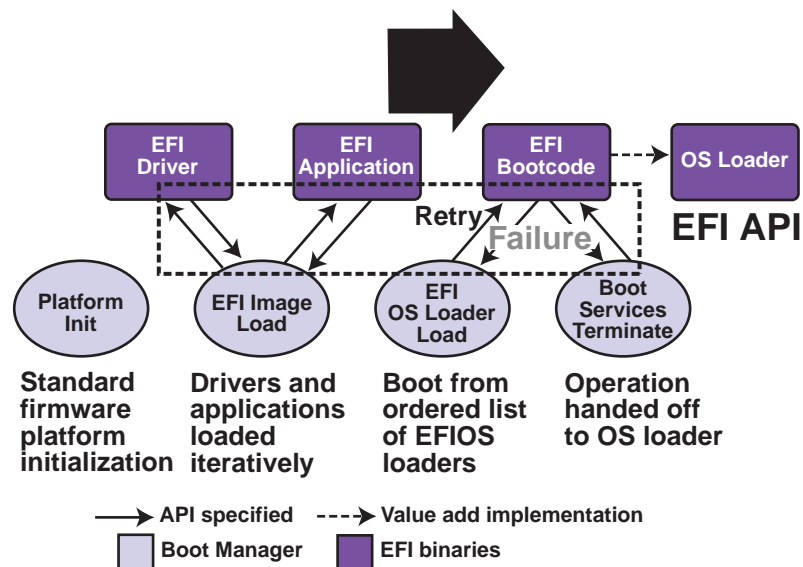

Figure 2. Booting Sequence

UEFI allows the consolidation of boot menus from the OS loader and platform firmware into a single platform firmware menu. These platform firmware menus will allow the selection of any UEFI OS loader from any partition on any boot medium that is supported by UEFI boot services. An UEFI OS loader can support multiple options that can appear on the user interface. It is also possible to include legacy boot options, such as booting from the A: or C: drive in the platform firmware boot menu.

UEFI supports booting from media that contain an UEFI OS loader or an UEFI-defined System Partition. An UEFI-defined System Partition is required by UEFI to boot from a block device. UEFI does not require any change to the first sector of a partition, so it is possible to build media that will boot on both legacy architectures and UEFI platforms.

2.1 Boot Manager

UEFI contains a boot manager that allows the loading of applications written to this specification (including OS 1st stage loader) or UEFI drivers from any file on an UEFI-defined file system or through the use of an UEFI-defined image loading service. UEFI defines NVRAM variables that are

used to point to the file to be loaded. These variables also contain application-specific data that are passed directly to the UEFI application. The variables also contain a human readable string that can be displayed in a menu to the user.

The variables defined by UEFI allow the system firmware to contain a boot menu that can point to all of the operating systems, and even multiple versions of the same operating systems. The design goal of UEFI was to have one set of boot menus that could live in platform firmware. UEFI specifies only the NVRAM variables used in selecting boot options. UEFI leaves the implementation of the menu system as value added implementation space.

UEFI greatly extends the boot flexibility of a system over the current state of the art in the PC-AT-class system. The PC-AT-class systems today are restricted to boot from the first floppy, hard drive, CD-ROM, USB keys, or network card attached to the system. Booting from a common hard drive can cause many interoperability problems between operating systems, and different versions of operating systems from the same vendor.

2.1.1 UEFI Images

UEFI Images are a class of files defined by UEFI that contain executable code. The most distinguishing feature of UEFI Images is that the first set of bytes in the UEFI Image file contains an image header that defines the encoding of the executable image.

UEFI uses a subset of the PE32+ image format with a modified header signature. The modification to the signature value in the PE32+ image is done to distinguish UEFI images from normal PE32 executables. The “+” addition to PE32 provides the 64-bit relocation fix-up extensions to standard PE32 format.

For images with the UEFI image signature, the *Subsystem* values in the PE image header are defined below. The major differences between image types are the memory type that the firmware will load the image into, and the action taken when the image’s entry point exits or returns. A UEFI application image is always unloaded when control is returned from the image’s entry point. A UEFI driver image is only unloaded if control is passed back with a UEFI error code.

```
// PE32+ Subsystem type for EFI images
#define EFI_IMAGE_SUBSYSTEM_EFI_APPLICATION      10
#define EFI_IMAGE_SUBSYSTEM_EFI_BOOT_SERVICE_DRIVER 11
#define EFI_IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER   12

// PE32+ Machine type for EFI images
#define EFI_IMAGE_MACHINE_IA32                   0x014c
#define EFI_IMAGE_MACHINE_IA64                   0x0200
#define EFI_IMAGE_MACHINE_EBC                     0x0EBC
#define EFI_IMAGE_MACHINE_x64                     0x8664
#define EFI_IMAGE_MACHINE_ARMTHUMB_MIXED         0x01C2
#define EFI_IMAGE_MACHINE_AARCH64                0xAA64
```

Note: *This image type is chosen to enable UEFI images to contain Thumb and Thumb2 instructions while defining the EFI interfaces themselves to be in ARM mode.*

Table 4. UEFI Image Memory Types

Subsystem Type	Code Memory Type	Data Memory Type
EFI_IMAGE_SUBSYSTEM_EFI_APPLICATION	EfiLoaderCode	EfiLoaderData
EFI_IMAGE_SUBSYSTEM_EFI_BOOT_SERVICE_DRIVER	EfiBootServicesCode	EfiBootServicesData
EFI_IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER	EfiRuntimeServicesCode	EfiRuntimeServicesData

The *Machine* value that is found in the PE image file header is used to indicate the machine code type of the image. The machine code types for images with the UEFI image signature are defined below. A given platform must implement the image type native to that platform and the image type for EFI Byte Code (EBC). Support for other machine code types is optional to the platform.

A UEFI image is loaded into memory through the [EFI_BOOT_SERVICES.LoadImage\(\)](#) Boot Service. This service loads an image with a PE32+ format into memory. This PE32+ loader is required to load all sections of the PE32+ image into memory. Once the image is loaded into memory, and the appropriate fix-ups have been performed, control is transferred to a loaded image at the *AddressOfEntryPoint* reference according to the normal indirect calling conventions of applications based on supported 32-bit or supported 64-bit processors. All other linkage to and from an UEFI image is done programmatically.

2.1.2 UEFI Applications

Applications written to this specification are loaded by the Boot Manager or by other UEFI applications. To load a UEFI application the firmware allocates enough memory to hold the image, copies the sections within the UEFI application image to the allocated memory, and applies the relocation fix-ups needed. Once done, the allocated memory is set to be the proper type for code and data for the image. Control is then transferred to the UEFI application's entry point. When the application returns from its entry point, or when it calls the Boot Service [EFI_BOOT_SERVICES.Exit\(\)](#), the UEFI application is unloaded from memory and control is returned to the UEFI component that loaded the UEFI application.

When the Boot Manager loads a UEFI application, the image handle may be used to locate the “load options” for the UEFI application. The load options are stored in nonvolatile storage and are associated with the UEFI application being loaded and executed by the Boot Manager.

2.1.3 UEFI OS Loaders

A UEFI OS loader is a special type of UEFI application that normally takes over control of the system from firmware conforming to this specification. When loaded, the UEFI OS loader behaves like any other UEFI application in that it must only use memory it has allocated from the firmware and can only use UEFI services and protocols to access the devices that the firmware exposes. If the UEFI OS loader includes any boot service style driver functions, it must use the proper UEFI interfaces to obtain access to the bus specific-resources. That is, I/O and memory-mapped device registers must be accessed through the proper bus specific I/O calls like those that a UEFI driver would perform.

If the UEFI OS loader experiences a problem and cannot load its operating system correctly, it can release all allocated resources and return control back to the firmware via the Boot Service [Exit\(\)](#)

call. The `Exit()` call allows both an error code and `ExitData` to be returned. The `ExitData` contains both a string and OS loader-specific data to be returned.

If the UEFI OS loader successfully loads its operating system, it can take control of the system by using the Boot Service `EFI_BOOT_SERVICES.ExitBootServices()`. After successfully calling `ExitBootServices()`, all boot services in the system are terminated, including memory management, and the UEFI OS loader is responsible for the continued operation of the system.

2.1.4 UEFI Drivers

UEFI drivers are loaded by the Boot Manager, firmware conforming to this specification, or by other UEFI applications. To load a UEFI driver the firmware allocates enough memory to hold the image, copies the sections within the UEFI driver image to the allocated memory and applies the relocation fix-ups needed. Once done, the allocated memory is set to be the proper type for code and data for the image. Control is then transferred to the UEFI driver's entry point. When the UEFI driver returns from its entry point, or when it calls the Boot Service `EFI_BOOT_SERVICES.Exit()`, the UEFI driver is optionally unloaded from memory and control is returned to the component that loaded the UEFI driver. A UEFI driver is not unloaded from memory if it returns a status code of `EFI_SUCCESS`. If the UEFI driver's return code is an error status code, then the driver is unloaded from memory.

There are two types of UEFI drivers: boot service drivers and runtime drivers. The only difference between these two driver types is that UEFI runtime drivers are available after a UEFI OS loader has taken control of the platform with the Boot Service `EFI_BOOT_SERVICES.ExitBootServices()`.

UEFI boot service drivers are terminated when `ExitBootServices()` is called, and all the memory resources consumed by the UEFI boot service drivers are released for use in the operating system environment.

A runtime driver of type `EFI_IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER` gets fixed up with virtual mappings when the OS calls `SetVirtualAddressMap()`.

2.2 Firmware Core

This section provides an overview of the services defined by UEFI. These include boot services and runtime services.

2.2.1 UEFI Services

The purpose of the UEFI interfaces is to define a common boot environment abstraction for use by loaded UEFI images, which include UEFI drivers, UEFI applications, and UEFI OS loaders. The calls are defined with a full 64-bit interface, so that there is headroom for future growth. The goal of this set of abstracted platform calls is to allow the platform and OS to evolve and innovate independently of one another. Also, a standard set of primitive runtime services may be used by operating systems.

Platform interfaces defined in this section allow the use of standard Plug and Play Option ROMs as the underlying implementation methodology for the boot services. The interfaces have been

designed in such a way as to map back into legacy interfaces. These interfaces have in no way been burdened with any restrictions inherent to legacy Option ROMs.

The UEFI platform interfaces are intended to provide an abstraction between the platform and the OS that is to boot on the platform. The UEFI specification also provides abstraction between diagnostics or utility programs and the platform; however, it does not attempt to implement a full diagnostic OS environment. It is envisioned that a small diagnostic OS-like environment can be easily built on top of an UEFI system. Such a diagnostic environment is not described by this specification.

Interfaces added by this specification are divided into the following categories and are detailed later in this document:

- Runtime services
- Boot services interfaces, with the following subcategories:
 - Global boot service interfaces
 - Device handle-based boot service interfaces
 - Device protocols
 - Protocol services

2.2.2 Runtime Services

This section describes UEFI runtime service functions. The primary purpose of the runtime services is to abstract minor parts of the hardware implementation of the platform from the OS. Runtime service functions are available during the boot process and also at runtime provided the OS switches into flat physical addressing mode to make the runtime call. However, if the OS loader or OS uses the Runtime Service [SetVirtualAddressMap\(\)](#) service, the OS will only be able to call runtime services in a virtual addressing mode. All runtime interfaces are non-blocking interfaces and can be called with interrupts disabled if desired. To ensure maximum compatibility with existing platforms it is recommended that all UEFI modules that comprise the Runtime Services be represented in the *MemoryMap* as a single **EFI_MEMORY_DESCRIPTOR** of Type **EfiRuntimeServicesCode**.

In all cases memory used by the runtime services must be reserved and not used by the OS. runtime services memory is always available to an UEFI function and will never be directly manipulated by the OS or its components. UEFI is responsible for defining the hardware resources used by runtime services, so the OS can synchronize with those resources when runtime service calls are made, or guarantee that the OS never uses those resources.

[Table 5](#) lists the Runtime Services functions.

Table 5. UEFI Runtime Services

Name	Description
GetTime()	Returns the current time, time context, and time keeping capabilities.
SetTime()	Sets the current time and time context.
GetWakeupTime()	Returns the current wakeup alarm settings.
SetWakeupTime()	Sets the current wakeup alarm settings.

Name	Description
<u>GetVariable ()</u>	Returns the value of a named variable.
<u>GetNextVariableName ()</u>	Enumerates variable names.
<u>SetVariable ()</u>	Sets, and if needed creates, a variable.
<u>SetVirtualAddressMap ()</u>	Switches all runtime functions from physical to virtual addressing.
<u>ConvertPointer ()</u>	Used to convert a pointer from physical to virtual addressing.
<u>GetNextHighMonotonicCount ()</u>	Subsumes the platform's monotonic counter functionality.
<u>ResetSystem ()</u>	Resets all processors and devices and reboots the system.
<u>UpdateCapsule ()</u>	Passes capsules to the firmware with both virtual and physical mapping.
<u>QueryCapsuleCapabilities ()</u>	Returns if the capsule can be supported via UpdateCapsule () .
<u>QueryVariableInfo ()</u>	Returns information about the EFI variable store.

2.3 Calling Conventions

Unless otherwise stated, all functions defined in the UEFI specification are called through pointers in common, architecturally defined, calling conventions found in C compilers. Pointers to the various global UEFI functions are found in the **EFI_RUNTIME_SERVICES** and **EFI_BOOT_SERVICES** tables that are located via the system table. Pointers to other functions defined in this specification are located dynamically through device handles. In all cases, all pointers to UEFI functions are cast with the word **EFIAPI**. This allows the compiler for each architecture to supply the proper compiler keywords to achieve the needed calling conventions. When passing pointer arguments to Boot Services, Runtime Services, and Protocol Interfaces, the caller has the following responsibilities:

- It is the caller's responsibility to pass pointer parameters that reference physical memory locations. If a pointer is passed that does not point to a physical memory location (i.e., a memory mapped I/O region), the results are unpredictable and the system may halt.
- It is the caller's responsibility to pass pointer parameters with correct alignment. If an unaligned pointer is passed to a function, the results are unpredictable and the system may halt.
- It is the caller's responsibility to not pass in a **NULL** parameter to a function unless it is explicitly allowed. If a **NULL** pointer is passed to a function, the results are unpredictable and the system may hang.
- Unless otherwise stated, a caller should not make any assumptions regarding the state of pointer parameters if the function returns with an error.
- A caller may not pass structures that are larger than native size by value and these structures must be passed by reference (via a pointer) by the caller. Passing a structure larger than native width (4 bytes on supported 32-bit processors; 8 bytes on supported 64-bit processor instructions) on the stack will produce undefined results.

Calling conventions for supported 32-bit and supported 64-bit applications are described in more detail below. Any function or protocol may return any valid return code.

All public interfaces of a UEFI module must follow the UEFI calling convention. Public interfaces include the image entry point, UEFI event handlers, and protocol member functions. The type EFI_API is used to indicate conformance to the calling conventions defined in this section. Non public interfaces, such as private functions and static library calls, are not required to follow the UEFI calling conventions and may be optimized by the compiler.

2.3.1 Data Types

[Table 6](#) lists the common data types that are used in the interface definitions, and [Table 7](#) lists their modifiers. Unless otherwise specified all data types are naturally aligned. Structures are aligned on boundaries equal to the largest internal datum of the structure and internal data are implicitly padded to achieve natural alignment.

The values of the pointers passed into or returned by the UEFI interfaces must provide natural alignment for the underlying types.

Table 6. Common UEFI Data Types

Mnemonic	Description
BOOLEAN	Logical Boolean. 1-byte value containing a 0 for FALSE or a 1 for TRUE . Other values are undefined.
INTN	Signed value of native width. (4 bytes on supported 32-bit processor instructions, 8 bytes on supported 64-bit processor instructions)
UINTN	Unsigned value of native width. (4 bytes on supported 32-bit processor instructions, 8 bytes on supported 64-bit processor instructions)
INT8	1-byte signed value.
UINT8	1-byte unsigned value.
INT16	2-byte signed value.
UINT16	2-byte unsigned value.
INT32	4-byte signed value.
UINT32	4-byte unsigned value.
INT64	8-byte signed value.
UINT64	8-byte unsigned value.
CHAR8	1-byte character. Unless otherwise specified, all 1-byte or ASCII characters and strings are stored in 8-bit ASCII encoding format, using the ISO-Latin-1 character set.
CHAR16	2-byte Character. Unless otherwise specified all characters and strings are stored in the UCS-2 encoding format as defined by Unicode 2.1 and ISO/IEC 10646 standards.
VOID	Undeclared type.
EFI_GUID	128-bit buffer containing a unique identifier value. Unless otherwise specified, aligned on a 64-bit boundary.
EFI_STATUS	Status code. Type UINTN.
EFI_HANDLE	A collection of related interfaces. Type VOID *.

Mnemonic	Description
EFI_EVENT	Handle to an event structure. Type VOID *.
EFI_LBA	Logical block address. Type UINT64.
EFI_TPL	Task priority level. Type UINTN.
EFI_MAC_ADDRESS	32-byte buffer containing a network Media Access Control address.
EFI_IPv4_ADDRESS	4-byte buffer. An IPv4 internet protocol address.
EFI_IPv6_ADDRESS	16-byte buffer. An IPv6 internet protocol address.
EFI_IP_ADDRESS	16-byte buffer aligned on a 4-byte boundary. An IPv4 or IPv6 internet protocol address.
<Enumerated Type>	Element of a standard ANSI C enum type declaration. Type INT32.or UINT32. ANSI C does not define the size of sign of an enum so they should never be used in structures. ANSI C integer promotion rules make INT32 or UINT32 interchangeable when passed as an argument to a function.
sizeof (VOID *)	4 bytes on supported 32-bit processor instructions. 8 bytes on supported 64-bit processor instructions.
Bitfields	Bitfields are ordered such that bit 0 is the least significant bit.

Table 7. Modifiers for Common UEFI Data Types

Mnemonic	Description
IN	Datum is passed to the function.
OUT	Datum is returned from the function.
OPTIONAL	Passing the datum to the function is optional, and a NULL may be passed if the value is not supplied.
CONST	Datum is read-only.
EFIAPI	Defines the calling convention for UEFI interfaces.

2.3.2 IA-32 Platforms

All functions are called with the C language calling convention. The general-purpose registers that are volatile across function calls are **eax**, **ecx**, and **edx**. All other general-purpose registers are nonvolatile and are preserved by the target function. In addition, unless otherwise specified by the function definition, all other registers are preserved.

Firmware boot services and runtime services run in the following processor execution mode prior to the OS calling ExitBootServices():

- Uniprocessor, as described in chapter 8.4 of:
 - *Intel 64 and IA-32 Architectures Software Developer's Manual*
 - Volume 3, System Programming Guide, Part 1
 - Order Number: 253668-033US, December 2009
 - See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading "Intel Processor Manuals.
- Protected mode

- Paging mode may be enabled. If paging mode is enabled, PAE (Physical Address Extensions) mode is recommended. If paging mode is enabled, any memory space defined by the UEFI memory map is identity mapped (virtual address equals physical address). The mappings to other regions are undefined and may vary from implementation to implementation.
- Selectors are set to be flat and are otherwise not used
- Interrupts are enabled—though no interrupt services are supported other than the UEFI boot services timer functions (All loaded device drivers are serviced synchronously by “polling.”)
- Direction flag in EFLAGS is clear
- Other general purpose flag registers are undefined
- 128 KiB, or more, of available stack space
- The stack must be 16-byte aligned. Stack may be marked as non-executable in identity mapped page tables.
- Floating-point control word must be initialized to 0x027F (all exceptions masked, double-precision, round-to-nearest)
- Multimedia-extensions control word (if supported) must be initialized to 0x1F80 (all exceptions masked, round-to-nearest, flush to zero for masked underflow).
- CR0.EM must be zero
- CR0.TS must be zero

An application written to this specification may alter the processor execution mode, but the UEFI image must ensure firmware boot services and runtime services are executed with the prescribed execution environment.

After an Operating System calls **ExitBootServices ()**, firmware boot services are no longer available and it is illegal to call any boot service. After **ExitBootServices**, firmware runtime services are still available and may be called with paging enabled and virtual address pointers if **SetVirtualAddressMap ()** has been called describing all virtual address ranges used by the firmware runtime service.

For an operating system to use any UEFI runtime services, it must:

- Preserve all memory in the memory map marked as runtime code and runtime data
- Call the runtime service functions, with the following conditions:
 - In protected mode
 - Paging may or may *not* be enabled, however if paging is enabled and **SetVirtualAddressMap ()** has not been called, any memory space defined by the UEFI memory map is identity mapped (virtual address equals physical address). The mappings to other regions are undefined and may vary from implementation to implementation. See description of [SetVirtualAddressMap \(\)](#) for details of memory map after this function has been called.
 - Direction flag in EFLAGS clear
 - 4 KiB, or more, of available stack space
 - The stack must be 16-byte aligned
 - Floating-point control word must be initialized to 0x027F (all exceptions masked, double-precision, round-to-nearest)

- Multimedia-extensions control word (if supported) must be initialized to 0x1F80 (all exceptions masked, round-to-nearest, flush to zero for masked underflow)
- CR0.EM must be zero
- CR0.TS must be zero
- Interrupts disabled or enabled at the discretion of the caller
- ACPI Tables loaded at boot time can be contained in memory of type **EfiACPIReclaimMemory** (recommended) or **EfiACPIMemoryNVS**. ACPI FACS must be contained in memory of type **EfiACPIMemoryNVS**.
- The system firmware must not request a virtual mapping for any memory descriptor of type **EfiACPIReclaimMemory** or **EfiACPIMemoryNVS**.
- EFI memory descriptors of type **EfiACPIReclaimMemory** and **EfiACPIMemoryNVS** must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- Any UEFI memory descriptor that requests a virtual mapping via the **EFI_MEMORY_DESCRIPTOR** having the **EFI_MEMORY_RUNTIME** bit set must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes, the ACPI Memory Op-region must inherit its cacheability attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.
- ACPI tables loaded at runtime must be contained in memory of type **EfiACPIMemoryNVS**. The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.
- In general, UEFI Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type **EfiRuntimeServicesData** (recommended and the system firmware must not request a virtual mapping), **EfiBootServicesData**, **EfiACPIReclaimMemory** or **EfiACPIMemoryNVS**. Tables loaded at runtime must be contained in memory of type **EfiRuntimeServicesData** (recommended) or **EfiACPIMemoryNVS**.

Note: *Previous EFI specifications allowed ACPI tables loaded at runtime to be in the **EfiReservedMemoryType** and there was no guidance provided for other EFI Configuration Tables. **EfiReservedMemoryType** is not intended to be used for the storage of any EFI Configuration Tables. Also, only OSes conforming to the UEFI Specification are guaranteed to handle SMBIOS table in memory of type **EfiBootServicesData**.*

2.3.2.1 Handoff State

When a 32-bit UEFI OS is loaded, the system firmware hands off control to the OS in flat 32-bit mode. All descriptors are set to their 4GiB limits so that all of memory is accessible from all segments.

Figure 3 shows the stack after `AddressOfEntryPoint` in the image's PE32+ header has been called on supported 32-bit systems. All UEFI image entry points take two parameters. These are the image handle of the UEFI image, and a pointer to the EFI System Table.

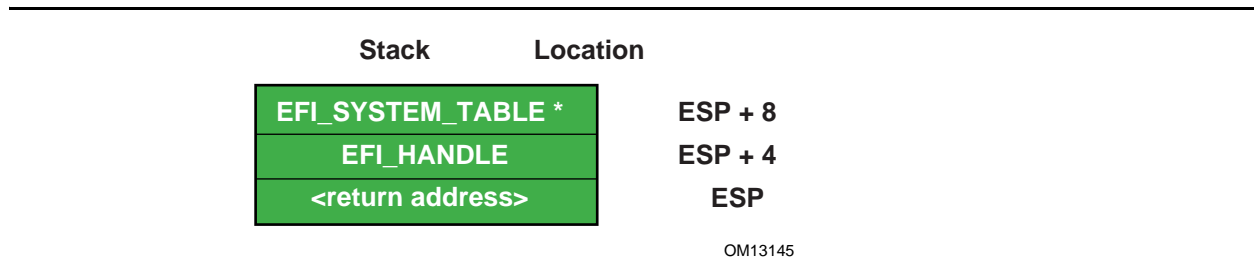

Figure 3. Stack after `AddressOfEntryPoint` Called, IA- 32

2.3.2.2 Calling Convention

All functions are called with the C language calling convention. The general-purpose registers that are volatile across function calls are `eax`, `ecx`, and `edx`. All other general-purpose registers are nonvolatile and are preserved by the target function.

In addition, unless otherwise specified by the function definition, all other CPU registers (including MMX and XMM) are preserved.

The floating point status register is not preserved by the target function. The floating point control register and MMX control register are saved by the target function.

If the return value is a float or a double, the value is returned in ST(0).

2.3.3 Intel[®] Itanium[®]-Based Platforms

UEFI executes as an extension to the SAL execution environment with the same rules as laid out by the SAL specification.

During boot services time the processor is in the following execution mode:

- Uniprocessor, as detailed in chapter 13.1.2 of:
 - *Intel Itanium Architecture Software Developer's Manual*
 - Volume 2: System Architecture
 - Revision 2.2
 - January 2006
 - See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “Intel Itanium Documentation”.
 - Document Number: 245318-005
- Physical mode
- 128 KiB, or more, of available stack space
- 16 KiB, or more, of available backing store space
 - FPSR.traps:Set to all 1's (all exceptions disabled)
 - FPSR.sf0:
 - .pc:Precision Control - 11b (extended precision)

- .rc:Rounding Control - 0 (round to nearest)
- .wre:Widest Range Exponent - 0 (IEEE mode)
- .ftz:Flush-To-Zero mode - 0 (off)
- FPSR.sf1:
 - .td:Traps Disable = 1 (traps disabled)
 - .pc:Precision Control - 11b (extended precision)
 - .rc:Rounding Control - 0 (round to nearest)
 - wreWidest Range Exponent - 1 (full register exponent range)
 - ftzFlush-To-Zero mode - 0 (off)
- FPSR.sf2,3:
 - .tdTraps Disable = 1 (traps disabled)
 - pc:Precision Control - 11b (extended precision)
 - .rc:Rounding Control - 0 (round to nearest)
 - .wre:Widest Range Exponent - 0 (IEEE mode)
 - .ftz:Flush-To-Zero mode - 0 (off)

An application written to this specification may alter the processor execution mode, but the UEFI image must ensure firmware boot services and runtime services are executed with the prescribed execution environment.

After an Operating System calls `ExitBootServices()`, firmware boot services are no longer available and it is illegal to call any boot service. After `ExitBootServices`, firmware runtime services are still available. When calling runtime services, paging may or may not be enabled, however if paging is enabled and `SetVirtualAddressMap()` has not been called, any memory space defined by the UEFI memory map is identity mapped (virtual address equals physical address). The mappings to other regions are undefined and may vary from implementation to implementation. See description of [SetVirtualAddressMap\(\)](#) for details of memory map after this function has been called. After `ExitBootServices()`, runtime service functions may be called with interrupts disabled or enabled at the discretion of the caller.

- ACPI Tables loaded at boot time can be contained in memory of type **EfiACPIReclaimMemory** (recommended) or **EfiACPIMemoryNVS**. ACPI FACS must be contained in memory of type **EfiACPIMemoryNVS**.
- The system firmware must not request a virtual mapping for any memory descriptor of type **EfiACPIReclaimMemory** or **EfiACPIMemoryNVS**.
- EFI memory descriptors of type **EfiACPIReclaimMemory** and **EfiACPIMemoryNVS** must be aligned on an 8 KiB boundary and must be a multiple of 8 KiB in size.
- Any UEFI memory descriptor that requests a virtual mapping via the **EFI_MEMORY_DESCRIPTOR** having the **EFI_MEMORY_RUNTIME** bit set must be aligned on an 8 KiB boundary and must be a multiple of 8 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes the ACPI Memory Op-region must inherit its cacheability attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.

- ACPI tables loaded at runtime must be contained in memory of type **EfiACPIMemoryNVS**. The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.
- In general, Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type **EfiRuntimeServicesData** (recommended and the system firmware must not request a virtual mapping), **EfiBootServicesData**, **EfiACPIReclaimMemory** or **EfiACPIMemoryNVS**. Tables loaded at runtime must be contained in memory of type **EfiRuntimeServicesData** (recommended) or **EfiACPIMemoryNVS**.

Note: Previous EFI specifications allowed ACPI tables loaded at runtime to be in the **EfiReservedMemoryType** and there was no guidance provided for other EFI Configuration Tables. **EfiReservedMemoryType** is not intended to be used by firmware. Also, only OSes conforming to the UEFI Specification are guaranteed to handle SMBIOS table in memory of type **EfiBootServicesData**.

Refer to the *IA-64 System Abstraction Layer Specification* (see [Appendix Q](#)) for details.

UEFI procedures are invoked using the P64 C calling conventions defined for Intel[®] Itanium[®]-based applications. Refer to the document *64 Bit Runtime Architecture and Software Conventions for IA-64* (see [Appendix Q](#)) for more information.

2.3.3.1 Handoff State

UEFI uses the standard P64 C calling conventions that are defined for Itanium-based operating systems. [Figure 4](#) shows the stack after **ImageEntryPoint** has been called on Itanium-based systems. The arguments are also stored in registers: **out0** contains **EFI_HANDLE** and **out1** contains the address of the **EFI_SYSTEM_TABLE**. The **gp** for the UEFI Image will have been loaded from the *label* pointed to by the *AddressOfEntryPoint* in the image's PE32+ header. All UEFI image entry points take two parameters. These are the image handle of the image, and a pointer to the System Table.

Figure 4. Stack after **AddressOfEntryPoint Called, Itanium-based Systems**

The SAL specification (see [Appendix Q](#)) defines the state of the system registers at boot handoff. The SAL specification also defines which system registers can only be used after UEFI boot services have been properly terminated.

2.3.3.2 Calling Convention

UEFI executes as an extension to the SAL execution environment with the same rules as laid out by the SAL specification. UEFI procedures are invoked using the P64 C calling conventions defined for Intel® Itanium®-based applications. Refer to the document 64 Bit Runtime Architecture and Software Conventions for IA-64 (see [Glossary](#) for more information).

For floating point, functions may only use the lower 32 floating point registers. Return values appear in f8-f15 registers. Single, double, and extended values are all returned using the appropriate format. Registers f6-f7 are local registers and are not preserved for the caller. All other floating point registers are preserved. Note that, when compiling UEFI programs, a special switch will likely need to be specified to guarantee that the compiler does not use f32-f127, which are not normally preserved in the regular calling convention for Itanium. A procedure using one of the preserved floating point registers must save and restore the caller's original contents without generating a NaT consumption fault.

Floating point arguments are passed in f8-f15 registers when possible. Parameters beyond the registers appear in memory, as explained in Section 8.5 of the Itanium Software Conventions and Runtime Architecture Guide. Within the called function, these are local registers and are not preserved for the caller. Registers f6-f7 are local registers and are not preserved for the caller. All other floating point registers are preserved. Note that, when compiling UEFI programs, a special switch will likely need to be specified to guarantee that the compiler does not use f32-f127, which are not normally preserved in the regular calling convention for Itanium. A procedure using one of the preserved floating point registers must save and restore the caller's original contents without generating a NaT consumption fault.

The floating point status register must be preserved across calls to a target function. Flags fields in SF1,2,3 are not preserved for the caller. Flags fields in SF0 upon return will reflect the value passed in, and with bits set to 1 corresponding to any IEEE exceptions detected on non-speculative floating-point operations executed as part of the callee.

Floating-point operations executed by the callee may require software emulation. The caller must be prepared to handle FP Software Assist (FPSWA) interruptions. Callees should not raise IEEE traps by changing FPSR.traps bits to 0 and then executing floating-point operations that raise such traps.

2.3.4 x64 Platforms

All functions are called with the C language calling convention. See [Section 2.3.4.2](#) for more detail. During boot services time the processor is in the following execution mode:

- Uniprocessor, as described in chapter 8.4 of:
 - *Intel 64 and IA-32 Architectures Software Developer's Manual*, Volume 3, System Programming Guide, Part 1, Order Number: 253668-033US, December 2009
 - See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “Intel Processor Manuals”.
- Long mode, in 64-bit mode
- Paging mode is enabled and any memory space defined by the UEFI memory map is identity mapped (virtual address equals physical address). The mappings to other regions are undefined and may vary from implementation to implementation.
- Selectors are set to be flat and are otherwise not used.

- Interrupts are enabled—though no interrupt services are supported other than the UEFI boot services timer functions (All loaded device drivers are serviced synchronously by “polling.”)
- Direction flag in EFLAGS is clear
- Other general purpose flag registers are undefined
- 128 KiB, or more, of available stack space
- The stack must be 16-byte aligned. Stack may be marked as non-executable in identity mapped page tables.
- Floating-point control word must be initialized to 0x037F (all exceptions masked, double-extended-precision, round-to-nearest)
- Multimedia-extensions control word (if supported) must be initialized to 0x1F80 (all exceptions masked, round-to-nearest, flush to zero for masked underflow).
- CR0.EM must be zero
- CR0.TS must be zero

For an operating system to use any UEFI runtime services, it must:

- Preserve all memory in the memory map marked as runtime code and runtime data
- Call the runtime service functions, with the following conditions:
 - In long mode, in 64-bit mode
 - Paging enabled
 - All selectors set to be flat with virtual = physical address. If the UEFI OS loader or OS used **SetVirtualAddressMap()** to relocate the runtime services in a virtual address space, then this condition does not have to be met. See description of [SetVirtualAddressMap\(\)](#) for details of memory map after this function has been called.
- Direction flag in EFLAGS clear
- 4 KiB, or more, of available stack space
- The stack must be 16-byte aligned
- Floating-point control word must be initialized to 0x037F (all exceptions masked, double-extended-precision, round-to-nearest)
- Multimedia-extensions control word (if supported) must be initialized to 0x1F80 (all exceptions masked, round-to-nearest, flush to zero for masked underflow)
- CR0.EM must be zero
- CR0.TS must be zero
- Interrupts may be disabled or enabled at the discretion of the caller.
- ACPI Tables loaded at boot time can be contained in memory of type **EfiACPIReclaimMemory** (recommended) or **EfiACPIMemoryNVS**. ACPI FACS must be contained in memory of type **EfiACPIMemoryNVS**.
- The system firmware must not request a virtual mapping for any memory descriptor of type **EfiACPIReclaimMemory** or **EfiACPIMemoryNVS**.
- EFI memory descriptors of type **EfiACPIReclaimMemory** and **EfiACPIMemoryNVS** must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.

- Any UEFI memory descriptor that requests a virtual mapping via the **EFI_MEMORY_DESCRIPTOR** having the **EFI_MEMORY_RUNTIME** bit set must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes, the ACPI Memory Op-region must inherit its cacheability attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.
- ACPI tables loaded at runtime must be contained in memory of type **EfiACPIMemoryNVS**. The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.
- In general, UEFI Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type **EfiRuntimeServicesData** (recommended and the system firmware must not request a virtual mapping), **EfiBootServicesData**, **EfiACPIReclaimMemory** or **EfiACPIMemoryNVS**. Tables loaded at runtime must be contained in memory of type **EfiRuntimeServicesData** (recommended) or **EfiACPIMemoryNVS**.

Note: *Previous EFI specifications allowed ACPI tables loaded at runtime to be in the **EfiReservedMemoryType** and there was no guidance provided for other EFI Configuration Tables. **EfiReservedMemoryType** is not intended to be used by firmware. Also, only OSes conforming to the UEFI Specification are guaranteed to handle SMBIOS table in memory of type **EfiBootServicesData**.*

2.3.4.1 Handoff State

Rcx – EFI_HANDLE

Rdx – EFI_SYSTEM_TABLE *

RSP - <return address>

2.3.4.2 Detailed Calling Conventions

The caller passes the first four integer arguments in registers. The integer values are passed from left to right in Rcx, Rdx, R8, and R9 registers. The caller passes arguments five and above onto the stack. All arguments must be right-justified in the register in which they are passed. This ensures the callee can process only the bits in the register that are required.

The caller passes arrays and strings via a pointer to memory allocated by the caller. The caller passes structures and unions of size 8, 16, 32, or 64 bits as if they were integers of the same size. The caller is not allowed to pass structures and unions of other than these sizes and must pass these unions and structures via a pointer.

The callee must dump the register parameters into their shadow space if required. The most common requirement is to take the address of an argument.

If the parameters are passed through varargs then essentially the typical parameter passing applies, including spilling the fifth and subsequent arguments onto the stack. The callee must dump the arguments that have their address taken.

Return values that fit into 64-bits are returned in the Rax register. If the return value does not fit within 64-bits, then the caller must allocate and pass a pointer for the return value as the first argument, Rcx. Subsequent arguments are then shifted one argument to the right, so for example argument one would be passed in Rdx. User-defined types to be returned must be 1,2,4,8,16,32, or 64 bits in length.

The registers Rax, Rcx Rdx R8, R9, R10, R11, and XMM0-XMM5 are volatile and are, therefore, destroyed on function calls.

The registers RBX, RBP, RDI, RSI, R12, R13, R14, R15, and XMM6-XMM15 are considered nonvolatile and must be saved and restored by a function that uses them.

Function pointers are pointers to the label of the respective function and don't require special treatment.

A caller must always call with the stack 16-byte aligned.

For MMX, XMM and floating-point values, return values that can fit into 64-bits are returned through RAX (including MMX types). However, XMM 128-bit types, floats, and doubles are returned in XMM0. The floating point status register is not saved by the target function. Floating-point and double-precision arguments are passed in XMM0 - XMM3 (up to 4) with the integer slot (RCX, RDX, R8, and R9) that would normally be used for that cardinal slot being ignored (see example) and vice versa. XMM types are never passed by immediate value but rather a pointer will be passed to memory allocated by the caller. MMX types will be passed as if they were integers of the same size. Callees must not unmask exceptions without providing correct exception handlers.

In addition, unless otherwise specified by the function definition, all other CPU registers (including MMX and XMM) are preserved.

2.3.4.3 Enabling Paging or Alternate Translations in an Application

Boot Services define an execution environment where paging is not enabled (supported 32-bit) or where translations are enabled but mapped virtual equal physical (x64) and this section will describe how to write an application with alternate translations or with paging enabled. Some Operating Systems require the OS Loader to be able to enable OS required translations at Boot Services time.

If a UEFI application uses its own page tables, GDT or IDT, the application must ensure that the firmware executes with each supplanted data structure. There are two ways that firmware conforming to this specification can execute when the application has paging enabled.

- Explicit firmware call
- Firmware preemption of application via timer event

An application with translations enabled can restore firmware required mapping before each UEFI call. However the possibility of preemption may require the translation enabled application to disable interrupts while alternate translations are enabled. It's legal for the translation enabled application to enable interrupts if the application catches the interrupt and restores the EFI firmware environment prior to calling the UEFI interrupt ISR. After the UEFI ISR context is executed it will return to the translation enabled application context and restore any mappings required by the application.

2.3.5 AArch32 Platforms

All functions are called with the C language calling convention specified in [Section 2.3.5.3](#). In addition, the invoking OSs can assume that unaligned access support is enabled if it is present in the processor.

During boot services time the processor is in the following execution mode:

- Unaligned access should be enabled if supported; Alignment faults are enabled otherwise.
- Uniprocessor.
- A privileged mode.
- The MMU is enabled (CP15 c1 System Control Register (SCTLR) SCTLR.M=1) and any RAM defined by the UEFI memory map is identity mapped (virtual address equals physical address). The mappings to other regions are undefined and may vary from implementation to implementation
- The core will be configured as follows (common across all processor architecture revisions):
 - MMU enabled
 - Instruction and Data caches enabled
 - Access flag disabled
 - Translation remap disabled
 - Little endian mode
 - Domain access control mechanism (if supported) will be configured to check access permission bits in the page descriptor
 - Fast Context Switch Extension (FCSE) must be disabled

This will be achieved by:

- Configuring the CP15 c1 System Control Register (SCTLR) as follows: I=1, C=1, B=0, TRE=0, AFE=0, M=1
- Configuring the CP15 c3 Domain Access Control Register (DACR) to 0x33333333.
- Configuring the CP15 c1 System Control Register (SCTLR), A=1 on ARMv4 and ARMv5, A=0, U=1 on ARMv6 and ARMv7.

The state of other system control register bits is not dictated by this specification.

- Implementations of boot services will enable architecturally manageable caches and TLBs i.e., those that can be managed directly using CP15 operations using mechanisms and procedures defined in the ARM Architecture Reference Manual. They should not enable caches requiring platform information to manage or invoke non-architectural cache/TLB lockdown mechanisms
- MMU configuration--Implementations must use only 4k pages and a single translation base register. On devices supporting multiple translation base registers, TTBR0 must be used solely. The binding does not mandate whether page tables are cached or un-cached.
- On processors implementing the ARMv4 through ARMv6K architecture definitions, the core is additionally configured to disable extended page tables support, if present.
This will be achieved by configuring the CP15 c1 System Control Register (SCTLR) as follows: XP=0

- On processors implementing the ARMv7 and later architecture definitions, the core will be configured to enable the extended page table format and disable the TEX remap mechanism. This will be achieved by configuring the CP15 c1 System Control Register (SCTLR) as follows: XP=1, TRE=0
- Interrupts are enabled—though no interrupt services are supported other than the UEFI boot services timer functions (All loaded device drivers are serviced synchronously by “polling.”)
- 128 KiB or more of available stack space

For an operating system to use any runtime services, it must:

- Preserve all memory in the memory map marked as runtime code and runtime data
- Call the runtime service functions, with the following conditions:
 - In a privileged mode.
 - The system address regions described by all the entries in the EFI memory map that have the **EFI_MEMORY_RUNTIME** bit set must be identity mapped as they were for the EFI boot environment. If the OS Loader or OS used SetVirtualAddressMap() to relocate the runtime services in a virtual address space, then this condition does not have to be met. See description of SetVirtualAddressMap() for details of memory map after this function has been called.
 - The processor must be in a mode in which it has access to the system address regions specified in the EFI memory map with the **EFI_MEMORY_RUNTIME** bit set.
 - 4 KiB, or more, of available stack space
 - Interrupts may be disabled or enabled at the discretion of the caller

An application written to this specification may alter the processor execution mode, but the invoking OS must ensure firmware boot services and runtime services are executed with the prescribed execution environment.

If ACPI is supported :

- ACPI Tables loaded at boot time can be contained in memory of type **EfiACPIReclaimMemory** (recommended) or **EfiACPIMemoryNVS**. ACPI FACS must be contained in memory of type **EfiACPIMemoryNVS**
- The system firmware must not request a virtual mapping for any memory descriptor of type **EfiACPIReclaimMemory** or **EfiACPIMemoryNVS**.
- EFI memory descriptors of type **EfiACPIReclaimMemory** and **EfiACPIMemoryNVS** must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- Any UEFI memory descriptor that requests a virtual mapping via the **EFI_MEMORY_DESCRIPTOR** having the **EFI_MEMORY_RUNTIME** bit set must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes, the ACPI Memory Op-region must inherit its cacheability attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.
- ACPI tables loaded at runtime must be contained in memory of type **EfiACPIMemoryNVS**. The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI

memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.

- In general, UEFI Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type **EfiRuntimeServicesData** (recommended and the system firmware must not request a virtual mapping), **EfiBootServicesData**, **EfiACPIReclaimMemory** or **EfiACPIMemoryNVS**. Tables loaded at runtime must be contained in memory of type **EfiRuntimeServicesData** (recommended) or **EfiACPIMemoryNVS**.

Note: *Previous EFI specifications allowed ACPI tables loaded at runtime to be in the **EfiReservedMemoryType** and there was no guidance provided for other EFI Configuration Tables. **EfiReservedMemoryType** is not intended to be used by firmware. Also, only OSes conforming to the UEFI Specification are guaranteed to handle SMBIOS table in memory of type **EfiBootServicesData**.*

2.3.5.1 Handoff State

R0 – EFI_HANDLE

R1 – EFI_SYSTEM_TABLE *

R14 – Return Address

2.3.5.2 Enabling Paging or Alternate Translations in an Application

Boot Services define a specific execution environment. This section will describe how to write an application that creates an alternative execution environment. Some Operating Systems require the OS Loader to be able to enable OS required translations at Boot Services time, and make other changes to the UEFI defined execution environment.

If a UEFI application uses its own page tables, or other processor state, the application must ensure that the firmware executes with each supplanted functionality. There are two ways that firmware conforming to this specification can execute in this alternate execution environment:

- Explicit firmware call
- Firmware preemption of application via timer event

An application with an alternate execution environment can restore the firmware environment before each UEFI call. However the possibility of preemption may require the alternate execution-enabled application to disable interrupts while the alternate execution environment is active. It's legal for the alternate execution environment enabled application to enable interrupts if the application catches the interrupt and restores the EFI firmware environment prior to calling the UEFI interrupt ISR. After the UEFI ISR context is executed it will return to the alternate execution environment enabled application context.

An alternate execution environment created by a UEFI application must not change the semantics or behavior of the MMU configuration created by the UEFI firmware prior to invoking **ExitBootServices()**, including the bit layout of the page table entries.

After an OS loader calls **ExitBootServices()** it should immediately configure the exception vector to point to appropriate code.

2.3.5.3 Detailed Calling Convention

The base calling convention for the ARM binding is defined here:

Procedure Call Standard for the ARM Architecture V2.06 (or later)

See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “Arm Architecture Base Calling Convention”.

This binding further constrains the calling convention in these ways:

- Calls to UEFI defined interfaces must be done assuming that the target code requires the ARM instruction set state. Images are free to use other instruction set states except when invoking UEFI interfaces.
- Floating point, SIMD, vector operations and other instruction set extensions must not be used.
- Only little endian operation is supported.
- The stack will maintain 8 byte alignment as described in the AAPCS for public interfaces.
- Use of coprocessor registers for passing call arguments must not be used
- Structures (or other types larger than 64-bits) must be passed by reference and not by value
- The EFI ARM platform binding defines register r9 as an additional callee-saved variable register.

2.3.6 AArch64 Platforms

AArch64 UEFI will only execute 64-bit ARM code, as the ARMv8 architecture does not allow for the mixing of 32-bit and 64-bit code at the same privilege level.

All functions are called with the C language calling convention specified in Detailed calling Convention section below. During boot services only a single processor is used for execution. All secondary processors must be either powered off or held in a quiescent state.

The primary processor is in the following execution mode:

- Unaligned access must be enabled.
- Use the highest 64 bit non secure privilege level available; Non-secure EL2 (Hyp) or Non-secure EL1(Kernel).
- The MMU is enabled and any RAM defined by the UEFI memory map is identity mapped (virtual address equals physical address). The mappings to other regions are undefined and may vary from implementation to implementation
- The core will be configured as follows:
 - MMU enabled
 - Instruction and Data caches enabled
 - Little endian mode
 - Stack Alignment Enforced
 - NOT Top Byte Ignored
 - Valid Physical Address Space
 - 4K Translation Granule

This will be achieved by:

1. Configuring the System Control Register SCTLR_EL2 or SCTLR_EL1:
 - EE=0, I=1, SA=1, C=1, A=0, M=1
2. Configuring the appropriate Translation Control Register:
 - TCR_EL2
 - TBI=0
 - PS must contain the valid Physical Address Space Size.
 - TG0=00
 - TCR_EL1
 - TBI0=0
 - IPS must contain the valid Intermediate Physical Address Space Size.
 - TG0=00

Note: *The state of other system control register bits is not dictated by this specification.*

- All floating point traps and exceptions will be disabled at the relevant exception levels (FPCR=0, CPACR_EL1.FPEN=11, CPTR_EL2.TFP=0). This implies that the FP unit will be enabled by default.
- Implementations of boot services will enable architecturally manageable caches and TLBs i.e., those that can be managed directly using implementation independent registers using mechanisms and procedures defined in the ARM Architecture Reference Manual. They should not enable caches requiring platform information to manage or invoke non-architectural cache/TLB lockdown mechanisms.
- MMU configuration: Implementations must use only 4k pages and a single translation base register. On devices supporting multiple translation base registers, TTBR0 must be used solely. The binding does not mandate whether page tables are cached or un-cached.
- Interrupts are enabled, though no interrupt services are supported other than the UEFI boot services timer functions (All loaded device drivers are serviced synchronously by “polling”). All UEFI interrupts must be routed to the IRQ vector only.
- The architecture generic timer must be initialized and enabled. The Counter Frequency register (CNTFRQ) must be programmed with the timer frequency. Timer access must be provided to non-secure EL1 and EL0 by setting bits EL1PCTEN and EL1PCEN in register CNTHCTL_EL2.
- 128 KiB or more of available stack space
- The ARM architecture allows mapping pages at a variety of granularities, including 4KiB and 64KiB. If a 64KiB physical page contains any 4KiB page with any of the following types listed below, then all 4KiB pages in the 64KiB page must use identical ARM Memory Page Attributes (as described in [Table 8](#)):
 - EfiRuntimeServicesCode
 - EfiRuntimeServicesData
 - EfiReserved
 - EfiACPIMemoryNVSMixed attribute mappings within a larger page are not allowed.

Note: This constraint allows a 64K paged based Operating System to safely map runtime services memory.

For an operating system to use any runtime services, Runtime services must:

- Support calls from either the EL1 or the EL2 exception levels.
- Once called, simultaneous or nested calls from EL1 and EL2 are not permitted.

Note: Sequential, non-overlapping, calls from EL1 and EL2 are permitted.

Runtime services are permitted to make synchronous SMC and HVC calls into higher exception levels.

Note: These rules allow Boot Services to start at EL2, and Runtime services to be assigned to an EL1 Operating System. In this case a call to **SetVirtualAddressMap ()** is expected to provided an EL1 appropriate set of mappings.

For an operating system to use any runtime services, it must:

- Enable unaligned access support.
- Preserve all memory in the memory map marked as runtime code and runtime data
- Call the runtime service functions, with the following conditions:
 - From either EL1 or EL2 exception levels.
 - Consistently call runtime services from the same exception level. Sharing of runtime services between different exception levels is not permitted.
 - Runtime services must only be assigned to a single operating system or hypervisor. They must not be shared between multiple guest operating systems.
 - The system address regions described by all the entries in the EFI memory map that have the **EFI_MEMORY_RUNTIME** bit set must be identity mapped as they were for the EFI boot environment. If the OS Loader or OS used **SetVirtualAddressMap ()** to relocate the runtime services in a virtual address space, then this condition does not have to be met. See description of **SetVirtualAddressMap ()** for details of memory map after this function has been called.
 - The processor must be in a mode in which it has access to the system address regions specified in the EFI memory map with the **EFI_MEMORY_RUNTIME** bit set.
 - 8 KiB, or more, of available stack space.
 - The stack must be 16-byte aligned (128-bit).
 - Interrupts may be disabled or enabled at the discretion of the caller

An application written to this specification may alter the processor execution mode, but the invoking OS must ensure firmware boot services and runtime services are executed with the prescribed execution environment.

If ACPI is supported :

- ACPI Tables loaded at boot time can be contained in memory of type **EfiACPIReclaimMemory** (recommended) or **EfiACPIMemoryNVS**.
- ACPI FACS must be contained in memory of type **EfiACPIMemoryNVS**. The system firmware must not request a virtual mapping for any memory descriptor of type **EfiACPIReclaimMemory** or **EfiACPIMemoryNVS**.

- EFI memory descriptors of type **EfiACPIReclaimMemory** and **EfiACPIMemoryNVS** must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- Any UEFI memory descriptor that requests a virtual mapping via the **EFI_MEMORY_DESCRIPTOR** having the **EFI_MEMORY_RUNTIME** bit set must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes, the ACPI Memory Op-region must inherit its cacheability attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.
- ACPI tables loaded at runtime must be contained in memory of type **EfiACPIMemoryNVS**. The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.
- In general, UEFI Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type **EfiRuntimeServicesData** (recommended and the system firmware must not request a virtual mapping), **EfiBootServicesdata**, **EfiACPIReclaimMemory** or **EfiACPIMemoryNVS**. Tables loaded at runtime must be contained in memory of type **EfiRuntimeServicesData** (recommended) or **EfiACPIMemoryNVS**.

Note: Previous EFI specifications allowed ACPI tables loaded at runtime to be in the **EfiReservedMemoryType** and there was no guidance provided for other EFI Configuration Tables. **EfiReservedMemoryType** is not intended to be used by firmware. UEFI 2.0 clarified the situation moving forward. Also, only Oses conforming to UEFI Specification are guaranteed to handle SMBIOS table in memory of type **EfiBootServiceData**.

2.3.6.1 Memory types

Table 8. Map: EFI memory types to AArch64 memory types

EFI Memory Type	ARM Memory Type: MAIR attribute encoding Attr<n> [7:4] [3:0]	ARM Memory Type: Meaning
EFI_MEMORY_UC (Not cacheable)	0000 0000	Device-nGnRnE (Device non-Gathering, non-Reordering, no Early Write Acknowledgement)
EFI_MEMORY_WC (Write combine)	0100 0100	Normal Memory Outer non-cacheable Inner non-cacheable
EFI_MEMORY_WT (Write through)	1011 1011	Normal Memory Outer Write-through non-transient Inner Write-through non-transient

EFI_MEMORY_WB (Write back)	1111 1111	Normal Memory Outer Write-back non-transient Inner Write-back non-transient
EFI_MEMORY_XP, EFI_MEMORY_WP, EFI_MEMORY_RP, EFI_MEMORY_UCE		Not used or defined

2.3.6.2 Handoff State

X0 – EFI_HANDLE

X1 – EFI_SYSTEM_TABLE *

X30 – Return Address

2.3.6.3 Enabling Paging or Alternate Translations in an Application

Boot Services define a specific execution environment. This section will describe how to write an application that creates an alternative execution environment. Some Operating Systems require the OS Loader to be able to enable OS required translations at Boot Services time, and make other changes to the UEFI defined execution environment.

If a UEFI application uses its own page tables, or other processor state, the application must ensure that the firmware executes with each supplanted functionality. There are two ways that firmware conforming to this specification can execute in this alternate execution environment:

- Explicit firmware call
- Firmware preemption of application via timer event

An application with an alternate execution environment can restore the firmware environment before each UEFI call. However the possibility of preemption may require the alternate execution-enabled application to disable interrupts while the alternate execution environment is active. It's legal for the alternate execution environment enabled application to enable interrupts if the application catches the interrupt and restores the EFI firmware environment prior to calling the UEFI interrupt ISR. After the UEFI ISR context is executed it will return to the alternate execution environment enabled application context.

An alternate execution environment created by a UEFI application must not change the semantics or behavior of the MMU configuration created by the UEFI firmware prior to invoking **ExitBootServices ()**, including the bit layout of the page table entries.

After an OS loader calls **ExitBootServices ()** it should immediately configure the exception vector to point to appropriate code.

2.3.6.4 Detailed Calling Convention

The base calling convention for the AArch64 binding is defined in the document *Procedure Call Standard for the ARM 64-bit Architecture Version A-0.06 (or later)*:

See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “ARM 64-bit Base Calling Convention”

This binding further constrains the calling convention in these ways:

- The AArch64 execution state must not be modified by the callee.
- All code exits, normal and exceptional, must be from the A64 instruction set.
- Floating point and SIMD instructions may be used.
- Optional vector operations and other instruction set extensions may only be used:
 - After dynamically checking for their existence.
 - Saving and then later restoring any additional execution state context.
 - Additional feature enablement or control, such as power, must be explicitly managed.
- Only little endian operation is supported.
- The stack will maintain 16 byte alignment.
- Structures (or other types larger than 64-bits) must be passed by reference and not by value.
- The EFI AArch64 platform binding defines the platform register (r18) as “do not use”. Avoiding use of r18 in firmware makes the code compatible with both a fixed role for r18 defined by the OS platform ABI and the use of r18 by the OS and its applications as a temporary register.

2.4 Protocols

The protocols that a device handle supports are discovered through the [EFI_BOOT_SERVICES.HandleProtocol\(\)](#) Boot Service or the [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) Boot Service. Each protocol has a specification that includes the following:

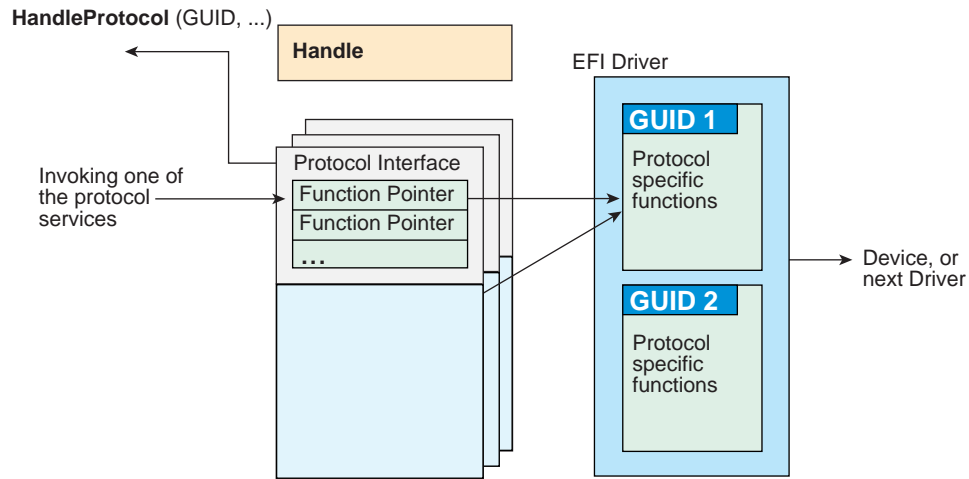

- The protocol’s globally unique ID (GUID)
- The Protocol Interface structure
- The Protocol Services

Unless otherwise specified a protocol’s interface structure is not allocated from runtime memory and the protocol member functions should not be called at runtime. If not explicitly specified a protocol member function can be called at a TPL level of less than or equal to **TPL_NOTIFY** (see [Section 6.1](#)). Unless otherwise specified a protocol’s member function is not reentrant or MP safe.

Any status codes defined by the protocol member function definition are required to be implemented, Additional error codes may be returned, but they will not be tested by standard compliance tests, and any software that uses the procedure cannot depend on any of the extended error codes that an implementation may provide.

To determine if the handle supports any given protocol, the protocol’s GUID is passed to **HandleProtocol()** or **OpenProtocol()**. If the device supports the requested protocol, a pointer to the defined Protocol Interface structure is returned. The Protocol Interface structure links the caller to the protocol-specific services to use for this device.

[Figure 5](#) shows the construction of a protocol. The UEFI driver contains functions specific to one or more protocol implementations, and registers them with the Boot Service [EFI_BOOT_SERVICES.InstallProtocolInterface\(\)](#). The firmware returns the Protocol Interface for the protocol that is then used to invoke the protocol specific services. The UEFI driver keeps private, device-specific context with protocol interfaces.

OM13147

Figure 5. Construction of a Protocol

The following C code fragment illustrates the use of protocols:

```
// There is a global "EffectsDevice" structure. This
// structure contains information pertinent to the device.

// Connect to the ILLUSTRATION_PROTOCOL on the EffectsDevice,
// by calling HandleProtocol with the device's EFI device handle
// and the ILLUSTRATION_PROTOCOL GUID.

EffectsDevice.Handle = DeviceHandle;
Status = HandleProtocol (
    EffectsDevice.EFIHandle,
    &IllustrationProtocolGuid,
    &EffectsDevice.IllustrationProtocol
);

// Use the EffectsDevice illustration protocol's "MakeEffects"
// service to make flashy and noisy effects.

Status = EffectsDevice.IllustrationProtocol->MakeEffects (
    EffectsDevice.IllustrationProtocol,
    TheFlashyAndNoisyEffect
);
```

[Table 9](#) lists the UEFI protocols defined by this specification.

Table 9. UEFI Protocols

Protocol	Description
<u>EFI LOADED IMAGE PROTOCOL</u>	Provides information on the image.
<u>EFI LOADED IMAGE DEVICE PATH PROTOCOL</u>	Specifies the device path that was used when a PE/COFF image was loaded through the EFI Boot Service LoadImage().
<u>EFI DEVICE PATH PROTOCOL</u>	Provides the location of the device.
<u>EFI DRIVER BINDING PROTOCOL</u>	Provides services to determine if an UEFI driver supports a given controller, and services to start and stop a given controller.
<u>EFI DRIVER FAMILY OVERRIDE PROTOCOL</u>	Provides a the Driver Family Override mechanism for selecting the best driver for a given controller.
<u>EFI PLATFORM DRIVER OVERRIDE PROTOCOL</u>	Provide a platform specific override mechanism for the selection of the best driver for a given controller.
<u>EFI BUS SPECIFIC DRIVER OVERRIDE PROTOCOL</u>	Provides a bus specific override mechanism for the selection of the best driver for a given controller.
<u>EFI DRIVER DIAGNOSTICS2 PROTOCOL</u>	Provides diagnostics services for the controllers that UEFI drivers are managing.
<u>EFI COMPONENT NAME2 PROTOCOL</u>	Provides human readable names for UEFI Drivers and the controllers that the drivers are managing.
<u>EFI SIMPLE TEXT INPUT PROTOCOL</u>	Protocol interfaces for devices that support simple console style text input.
<u>EFI SIMPLE TEXT OUTPUT PROTOCOL</u>	Protocol interfaces for devices that support console style text displaying.
<u>EFI SIMPLE POINTER PROTOCOL</u>	Protocol interfaces for devices such as mice and trackballs.
<u>EFI SERIAL IO PROTOCOL</u>	Protocol interfaces for devices that support serial character transfer.
<u>EFI LOAD FILE PROTOCOL</u>	Protocol interface for reading a file from an arbitrary device.
<u>EFI LOAD FILE2 PROTOCOL</u>	Protocol interface for reading a non-boot option file from an arbitrary device
<u>EFI SIMPLE FILE SYSTEM PROTOCOL</u>	Protocol interfaces for opening disk volume containing a UEFI file system.
<u>EFI FILE PROTOCOL</u>	Provides access to supported file systems.
<u>EFI DISK IO PROTOCOL</u>	A protocol interface that layers onto any BLOCK_IO or BLOCK_IO_EX interface.
<u>EFI BLOCK IO PROTOCOL</u>	Protocol interfaces for devices that support block I/O style accesses.
<u>EFI BLOCK IO2 PROTOCOL</u>	Protocol interfaces for devices that support block I/O style accesses. This interface is capable of non-blocking transactions.
<u>EFI UNICODE COLLATION PROTOCOL</u>	Protocol interfaces for string comparison operations.
<u>EFI PCI ROOT BRIDGE IO PROTOCOL</u>	Protocol interfaces to abstract memory, I/O, PCI configuration, and DMA accesses to a PCI root bridge controller.

Protocol	Description
<u>EFI PCI IO PROTOCOL</u>	Protocol interfaces to abstract memory, I/O, PCI configuration, and DMA accesses to a PCI controller on a PCI bus.
<u>EFI USB IO PROTOCOL</u>	Protocol interfaces to abstract access to a USB controller.
<u>EFI SIMPLE NETWORK PROTOCOL</u>	Provides interface for devices that support packet based transfers.
<u>EFI PXE BASE CODE PROTOCOL</u>	Protocol interfaces for devices that support network booting.
<u>EFI BIS PROTOCOL</u>	Protocol interfaces to validate boot images before they are loaded and invoked.
<u>EFI DEBUG SUPPORT PROTOCOL</u>	Protocol interfaces to save and restore processor context and hook processor exceptions.
<u>EFI DEBUGPORT PROTOCOL</u>	Protocol interface that abstracts a byte stream connection between a debug host and a debug target system.
<u>EFI DECOMPRESS PROTOCOL</u>	Protocol interfaces to decompress an image that was compressed using the EFI Compression Algorithm.
<u>EFI EBC PROTOCOL</u>	Protocols interfaces required to support an EFI Byte Code interpreter.
<u>EFI GRAPHICS OUTPUT PROTOCOL</u>	Protocol interfaces for devices that support graphical output.
<u>EFI NVM EXPRESS PASS THRU PROTOCOL</u>	Protocol interfaces that allow NVM Express commands to be issued to an NVM Express controller.
<u>EFI EXT SCSI PASS THRU PROTOCOL</u>	Protocol interfaces for a SCSI channel that allows SCSI Request Packets to be sent to SCSI devices.
<u>EFI USB2 HC PROTOCOL</u>	Protocol interfaces to abstract access to a USB Host Controller.
<u>EFI AUTHENTICATION INFO PROTOCOL</u>	Provides access for generic authentication information associated with specific device paths
<u>EFI DEVICE PATH UTILITIES PROTOCOL</u>	Aids in creating and manipulating device paths.
<u>EFI DEVICE PATH TO TEXT PROTOCOL</u>	Converts device nodes and paths to text.
<u>EFI DEVICE PATH FROM TEXT PROTOCOL</u>	Converts text to device paths and device nodes.
<u>EFI EDID DISCOVERED PROTOCOL</u>	Contains the EDID information retrieved from a video output device.
<u>EFI EDID ACTIVE PROTOCOL</u>	Contains the EDID information for an active video output device.
<u>EFI EDID OVERRIDE PROTOCOL</u>	Produced by the platform to allow the platform to provide EDID information to the producer of the Graphics Output protocol
<u>EFI ISCSI INITIATOR NAME PROTOCOL</u>	Sets and obtains the iSCSI Initiator Name.
<u>EFI TAPE IO PROTOCOL</u>	Provides services to control and access a tape drive.
<u>EFI MANAGED NETWORK PROTOCOL</u>	Used to locate communication devices that are supported by an MNP driver and create and destroy instances of the MNP child protocol driver that can use the underlying communications devices.

Protocol	Description
<u>EFI ARP SERVICE BINDING PROTOCOL</u>	Used to locate communications devices that are supported by an ARP driver and to create and destroy instances of the ARP child protocol driver.
<u>EFI ARP PROTOCOL</u>	Used to resolve local network protocol addresses into network hardware addresses.
<u>EFI DHCP4 SERVICE BINDING PROTOCOL</u>	Used to locate communication devices that are supported by an EFI DHCPv4 Protocol driver and to create and destroy EFI DHCPv4 Protocol child driver instances that can use the underlying communications devices.
<u>EFI DHCP4 PROTOCOL</u>	Used to collect configuration information for the EFI IPv4 Protocol drivers and to provide DHCPv4 server and PXE boot server discovery services.
<u>EFI TCP4 SERVICE BINDING PROTOCOL</u>	Used to locate EFI TCPv4 Protocol drivers to create and destroy child of the driver to communicate with other host using TCP protocol.
<u>EFI TCP4 PROTOCOL</u>	Provides services to send and receive data stream.
<u>EFI IP4 SERVICE BINDING PROTOCOL</u>	Used to locate communication devices that are supported by an EFI IPv4 Protocol Driver and to create and destroy instances of the EFI IPv4 Protocol child protocol driver that can use the underlying communication device.
<u>EFI IP4 PROTOCOL</u>	Provides basic network IPv4 packet I/O services.
<u>EFI IP4 CONFIG PROTOCOL</u>	The EFI IPv4 Config Protocol driver performs platform- and policy-dependent configuration of the EFI IPv4 Protocol driver.
<u>EFI IP4 CONFIG2 PROTOCOL</u>	The EFI IPv4 Configuration II Protocol driver performs platform- and policy-dependent configuration of the EFI IPv4 Protocol driver.
<u>EFI UDP4 SERVICE BINDING PROTOCOL</u>	Used to locate communication devices that are supported by an EFI UDPv4 Protocol driver and to create and destroy instances of the EFI UDPv4 Protocol child protocol driver that can use the underlying communication device.
<u>EFI UDP4 PROTOCOL</u>	Provides simple packet-oriented services to transmit and receive UDP packets.
<u>EFI MTFTP4 SERVICE BINDING PROTOCOL</u>	Used to locate communication devices that are supported by an EFI MTFTPv4 Protocol driver and to create and destroy instances of the EFI MTFTPv4 Protocol child protocol driver that can use the underlying communication device.
<u>EFI MTFTP4 PROTOCOL</u>	Provides basic services for client-side unicast or multicast TFTP operations.
<u>EFI HASH PROTOCOL</u>	Allows creating a hash of an arbitrary message digest using one or more hash algorithms.
<u>EFI HASH SERVICE BINDING PROTOCOL</u>	Used to locate hashing services support provided by a driver and create and destroy instances of the EFI Hash Protocol so that a multiple drivers can use the underlying hashing services.
<u>EFI SD MMC PASS THRU PROTOCOL</u>	Protocol interface that allows SD/eMMC commands to be sent to an SD/eMMC controller.

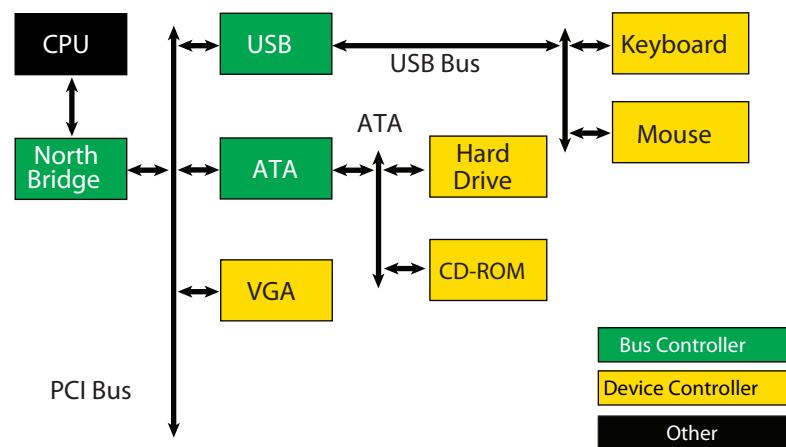

2.5 UEFI Driver Model

The *UEFI Driver Model* is intended to simplify the design and implementation of device drivers, and produce small executable image sizes. As a result, some complexity has been moved into bus drivers and in a larger part into common firmware services.

A device driver is required to produce a Driver Binding Protocol on the same image handle on which the driver was loaded. It then waits for the system firmware to connect the driver to a controller. When that occurs, the device driver is responsible for producing a protocol on the controller's device handle that abstracts the I/O operations that the controller supports. A bus driver performs these exact same tasks. In addition, a bus driver is also responsible for discovering any child controllers on the bus, and creating a device handle for each child controller found.

One assumption is that the architecture of a system can be viewed as a set of one or more processors connected to one or more core chipsets. The core chipsets are responsible for producing one or more I/O buses. The *UEFI Driver Model* does not attempt to describe the processors or the core chipsets. Instead, the *UEFI Driver Model* describes the set of I/O buses produced by the core chipsets, and any children of these I/O buses. These children can either be devices or additional I/O buses. This can be viewed as a tree of buses and devices with the core chipsets at the root of that tree.

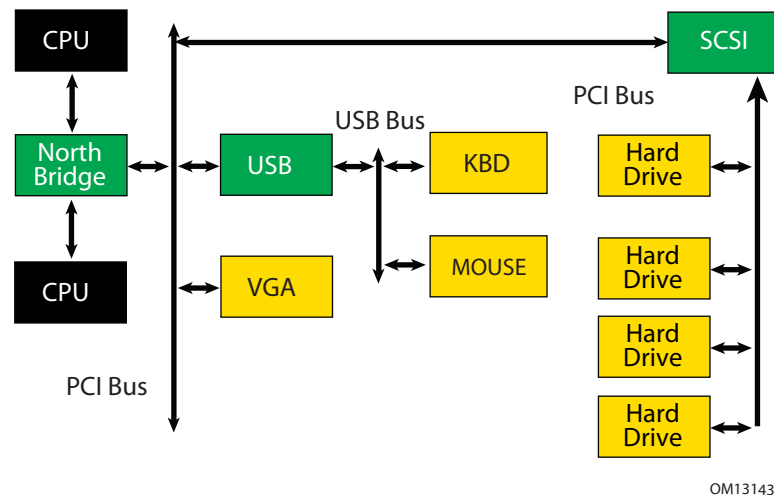

The leaf nodes in this tree structure are peripherals that perform some type of I/O. This could include keyboards, displays, disks, network, etc. The nonleaf nodes are the buses that move data between devices and buses, or between different bus types. [Figure 6](#) shows a sample desktop system with four buses and six devices.

OM13142

Figure 6. Desktop System

[Figure 7](#) is an example of a more complex server system. The idea is to make the *UEFI Driver Model* simple and extensible so more complex systems like the one below can be described and managed in the preboot environment. This system contains six buses and eight devices.

OM13143

Figure 7. Server System

The combination of firmware services, bus drivers, and device drivers in any given platform is likely to be produced by a wide variety of vendors including OEMs, IBVs, and IHVs. These different components from different vendors are required to work together to produce a protocol for an I/O device than can be used to boot a UEFI compliant operating system. As a result, the *UEFI Driver Model* is described in great detail in order to increase the interoperability of these components.

This remainder of this section is a brief overview of the *UEFI Driver Model*. It describes the legacy option ROM issues that the *UEFI Driver Model* is designed to address, the entry point of a driver, host bus controllers, properties of device drivers, properties of bus drivers, and how the *UEFI Driver Model* can accommodate hot-plug events.

2.5.1 Legacy Option ROM Issues

Legacy option ROMs have a number of constraints and limitations that restrict innovation on the part of platform designers and adapter vendors. At the time of writing, both ISA and PCI adapters use legacy option ROMs. For the purposes of this discussion, only PCI option ROMs will be considered; legacy ISA option ROMs are not supported as part of the *UEFI Specification*.

The following is a list of the major constraints and limitations of legacy option ROMs. For each issue, the design considerations that went into the design of the *UEFI Driver Model* are also listed. Thus, the design of the *UEFI Driver Model* directly addresses the requirements for a solution to overcome the limitations implicit to PC-AT-style legacy option ROMs.

2.5.1.1 32-bit/16-Bit Real Mode Binaries

Legacy option ROMs typically contain 16-bit real mode code for an IA-32 processor. This means that the legacy option ROM on a PCI card cannot be used in platforms that do not support the execution of IA-32 real mode binaries. Also, 16-bit real mode only allows the driver to access directly the lower 1 MiB of system memory. It is possible for the driver to switch the processor into modes other than real mode in order to access resources above 1 MiB, but this requires a lot of additional code, and causes interoperability issues with other option ROMs and the system BIOS.

Also, option ROMs that switch the processor into to alternate execution modes are not compatible with Itanium Processors.

UEFI *Driver Model* design considerations:

- Drivers need flat memory mode with full access to system components.
- Drivers need to be written in C so they are portable between processor architectures.
- Drivers may be compiled into a virtual machine executable, allowing a single binary driver to work on machines using different processor architectures.

2.5.1.2 Fixed Resources for Working with Option ROMs

Since legacy option ROMs can only directly address the lower 1 MiB of system memory, this means that the code from the legacy option ROM must exist below 1 MiB. In a PC-AT platform, memory from 0x00000-0x9FFFF is system memory. Memory from 0xA0000-0xBFFFF is VGA memory, and memory from 0xF0000-0xFFFFF is reserved for the system BIOS. Also, since system BIOS has become more complex over the years, many platforms also use 0xE0000-0xEFFFF for system BIOS. This leaves 128 KiB of memory from 0xC0000-0xDFFFF for legacy option ROMs. This limits how many legacy option ROMs can be run during BIOS POST.

Also, it is not easy for legacy option ROMs to allocate system memory. Their choices are to allocate memory from Extended BIOS Data Area (EBDA), allocate memory through a Post Memory Manager (PMM), or search for free memory based on a heuristic. Of these, only EBDA is standard, and the others are not used consistently between adapters, or between BIOS vendors, which adds complexity and the potential for conflicts.

UEFI *Driver Model* design considerations:

- Drivers need flat memory mode with full access to system components.
- Drivers need to be capable of being relocated so that they can be loaded anywhere in memory (PE/COFF Images)
- Drivers should allocate memory through the boot services. These are well-specified interfaces, and can be guaranteed to function as expected across a wide variety of platform implementations.

2.5.1.3 Matching Option ROMs to their Devices

It is not clear which controller may be managed by a particular legacy option ROM. Some legacy option ROMs search the entire system for controllers to manage. This can be a lengthy process depending on the size and complexity of the platform. Also, due to limitation in BIOS design, all the legacy option ROMs must be executed, and they must scan for all the peripheral devices before an operating system can be booted. This can also be a lengthy process, especially if SCSI buses must be scanned for SCSI devices. This means that legacy option ROMs are making policy decision about how the platform is being initialized, and which controllers are managed by which legacy option ROMs. This makes it very difficult for a system designer to predict how legacy option ROMs will interact with each other. This can also cause issues with on-board controllers, because a legacy option ROM may incorrectly choose to manage the on-board controller.

UEFI *Driver Model* design considerations:

- Driver to controller matching must be deterministic

- Give OEMs more control through Platform Driver Override Protocol and Driver Configuration Protocol
- It must be possible to start only the drivers and controllers required to boot an operating system.

2.5.1.4 Ties to PC-AT System Design

Legacy option ROMs assume a PC-AT-like system architecture. Many of them include code that directly touches hardware registers. This can make them incompatible on legacy-free and headless platforms. Legacy option ROMs may also contain setup programs that assume a PC-AT-like system architecture to interact with a keyboard or video display. This makes the setup application incompatible on legacy-free and headless platforms.

UEFI *Driver Model* design considerations:

- Drivers should use well-defined protocols to interact with system hardware, system input devices, and system output devices.

2.5.1.5 Ambiguities in Specification and Workarounds Born of Experience

Many legacy option ROMs and BIOS code contain workarounds because of incompatibilities between legacy option ROMs and system BIOS. These incompatibilities exist in part because there are no clear specifications on how to write a legacy option ROM or write a system BIOS.

Also, interrupt chaining and boot device selection is very complex in legacy option ROMs. It is not always clear which device will be the boot device for the OS.

UEFI *Driver Model* design considerations:

- Drivers and firmware are written to follow this specification. Since both components have a clearly defined specification, compliance tests can be developed to prove that drivers and system firmware are compliant. This should eliminate the need to build workarounds into either drivers or system firmware (other than those that might be required to address specific hardware issues).
- Give OEMs more control through Platform Driver Override Protocol and Driver Configuration Protocol and other OEM value-add components to manage the boot device selection process.

2.5.2 Driver Initialization

The file for a driver image must be loaded from some type of media. This could include ROM, FLASH, hard drives, floppy drives, CD-ROM, or even a network connection. Once a driver image has been found, it can be loaded into system memory with the boot service

[EFI_BOOT_SERVICES.LoadImage\(\)](#). **LoadImage()** loads a PE/COFF formatted image into system memory. A handle is created for the driver, and a Loaded Image Protocol instance is placed on that handle. A handle that contains a Loaded Image Protocol instance is called an *Image Handle*. At this point, the driver has not been started. It is just sitting in memory waiting to be started. [Figure 8](#) shows the state of an image handle for a driver after **LoadImage()** has been called.

Figure 8. Image Handle

After a driver has been loaded with the boot service **LoadImage ()**, it must be started with the boot service [EFI_BOOT_SERVICES.StartImage \(\)](#). This is true of all types of UEFI Applications and UEFI Drivers that can be loaded and started on an UEFI-compliant system. The entry point for a driver that follows the UEFI *Driver Model* must follow some strict rules. First, it is not allowed to touch any hardware. Instead, the driver is only allowed to install protocol instances onto its own *Image Handle*. A driver that follows the UEFI *Driver Model* is *required* to install an instance of the Driver Binding Protocol onto its own *Image Handle*. It may optionally install the Driver Configuration Protocol, the Driver Diagnostics Protocol, or the Component Name Protocol. In addition, if a driver wishes to be unloadable it may optionally update the Loaded Image Protocol (see [Section 8](#)) to provide its own [Unload \(\)](#) function. Finally, if a driver needs to perform any special operations when the boot service [EFI_BOOT_SERVICES.ExitBootServices \(\)](#) is called, it may optionally create an event with a notification function that is triggered when the boot service **ExitBootServices ()** is called. An *Image Handle* that contains a Driver Binding Protocol instance is known as a *Driver Image Handle*. [Figure 9](#) shows a possible configuration for the *Image Handle* from [Figure 8](#) after the boot service **StartImage ()** has been called.

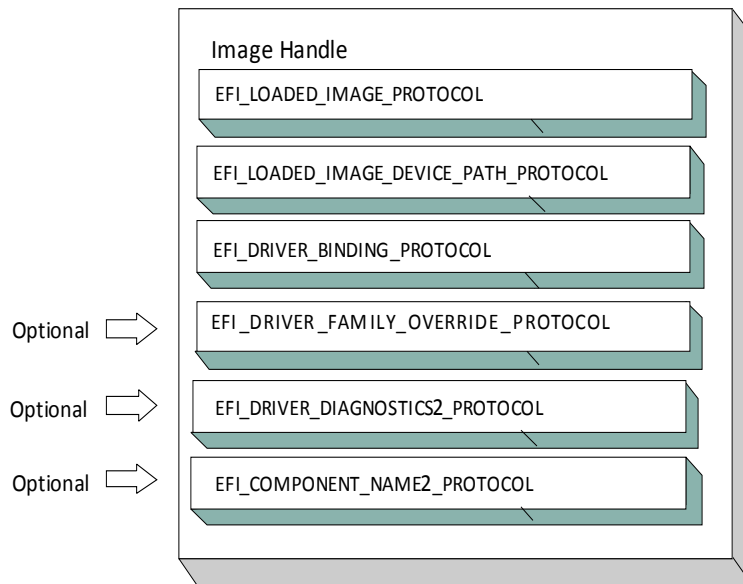

Figure 9. Driver Image Handle

2.5.3 Host Bus Controllers

Drivers are not allowed to touch any hardware in the driver’s entry point. As a result, drivers will be loaded and started, but they will all be waiting to be told to manage one or more controllers in the system. A platform component, like the Boot Manager, is responsible for managing the connection of drivers to controllers. However, before even the first connection can be made, there has to be some initial collection of controllers for the drivers to manage. This initial collection of controllers is known as the *Host Bus Controllers*. The I/O abstractions that the *Host Bus Controllers* provide are produced by firmware components that are outside the scope of the *UEFI Driver Model*. The device handles for the *Host Bus Controllers* and the I/O abstraction for each one must be produced by the core firmware on the platform, or a driver that may not follow the *UEFI Driver Model*. See the *PCI Root Bridge I/O Protocol Specification* for an example of an I/O abstraction for PCI buses.

A platform can be viewed as a set of processors and a set of core chipset components that may produce one or more host buses. [Figure 10](#) shows a platform with n processors (CPUs), and a set of core chipset components that produce m host bridges.

OM13150

Figure 10. Host Bus Controllers

Each host bridge is represented in UEFI as a device handle that contains a Device Path Protocol instance, and a protocol instance that abstracts the I/O operations that the host bus can perform. For example, a PCI Host Bus Controller supports one or more PCI Root Bridges that are abstracted by the PCI Root Bridge I/O Protocol. [Figure 11](#) shows an example device handle for a PCI Root Bridge.

OM13151

Figure 11. PCI Root Bridge Device Handle

A PCI Bus Driver could connect to this PCI Root Bridge, and create child handles for each of the PCI devices in the system. PCI Device Drivers should then be connected to these child handles, and produce I/O abstractions that may be used to boot a UEFI compliant OS. The following section describes the different types of drivers that can be implemented within the UEFI *Driver Model*. The UEFI *Driver Model* is very flexible, so all the possible types of drivers will not be discussed here.

Instead, the major types will be covered that can be used as a starting point for designing and implementing additional driver types.

2.5.4 Device Drivers

A device driver is not allowed to create any new device handles. Instead, it installs additional protocol interfaces on an existing device handle. The most common type of device driver will attach an I/O abstraction to a device handle that was created by a bus driver. This I/O abstraction may be used to boot a UEFI compliant OS. Some example I/O abstractions would include Simple Text Output, Simple Input, Block I/O, and Simple Network Protocol. [Figure 12](#) shows a device handle before and after a device driver is connected to it. In this example, the device handle is a child of the XYZ Bus, so it contains an XYZ I/O Protocol for the I/O services that the XYZ bus supports. It also contains a Device Path Protocol that was placed there by the XYZ Bus Driver. The Device Path Protocol is not required for all device handles. It is only required for device handles that represent physical devices in the system. Handles for virtual devices will not contain a Device Path Protocol.

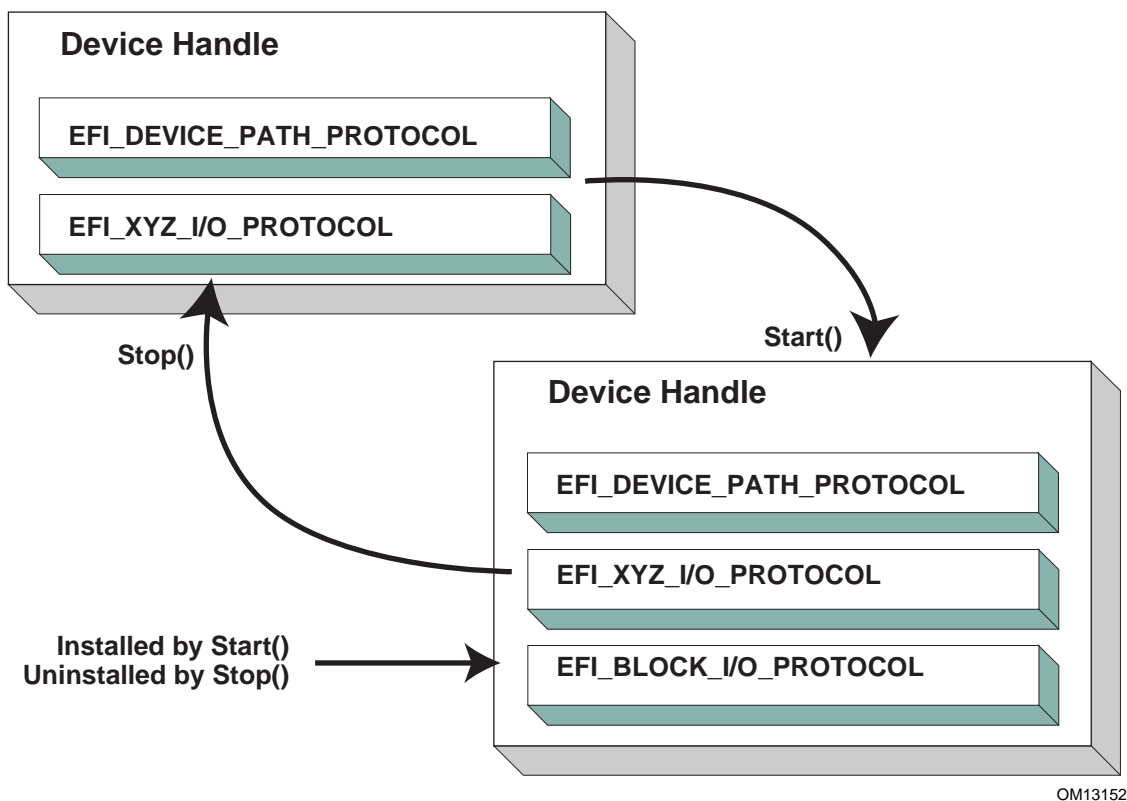

Figure 12. Connecting Device Drivers

The device driver that connects to the device handle in [Figure 12](#) must have installed a Driver Binding Protocol on its own image handle. The Driver Binding Protocol (see [Section 10.1](#)) contains three functions called `Supported()`, `Start()`, and `Stop()`. The `Supported()` function tests to see if the driver supports a given controller. In this example, the driver will check to see if the device handle supports the Device Path Protocol and the XYZ I/O Protocol. If a driver's

Supported() function passes, then the driver can be connected to the controller by calling the driver's **Start()** function. The **Start()** function is what actually adds the additional I/O protocols to a device handle. In this example, the Block I/O Protocol is being installed. To provide symmetry, the Driver Binding Protocol also has a **Stop()** function that forces the driver to stop managing a device handle. This will cause the device driver to uninstall any protocol interfaces that were installed in **Start()**.

The **Supported()**, **Start()**, and **Stop()** functions of the EFI Driver Binding Protocol are required to make use of the boot service [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) to get a protocol interface and the boot service [EFI_BOOT_SERVICES.CloseProtocol\(\)](#) to release a protocol interface. **OpenProtocol()** and **CloseProtocol()** update the handle database maintained by the system firmware to track which drivers are consuming protocol interfaces. The information in the handle database can be used to retrieve information about both drivers and controllers. The new boot service [EFI_BOOT_SERVICES.OpenProtocolInformation\(\)](#) can be used to get the list of components that are currently consuming a specific protocol interface.

2.5.5 Bus Drivers

Bus drivers and device drivers are virtually identical from the UEFI *Driver Model*'s point of view. The only difference is that a bus driver creates new device handles for the child controllers that the bus driver discovers on its bus. As a result, bus drivers are slightly more complex than device drivers, but this in turn simplifies the design and implementation of device drivers. There are two major types of bus drivers. The first creates handles for all child controllers on the first call to **Start()**. The other type allows the handles for the child controllers to be created across multiple calls to **Start()**. This second type of bus driver is very useful in supporting a rapid boot capability. It allows a few child handles or even one child handle to be created. On buses that take a long time to enumerate all of their children (e.g. SCSI), this can lead to a very large timesaving in booting a platform. [Figure 13](#) shows the tree structure of a bus controller before and after **Start()** is called. The dashed line coming into the bus controller node represents a link to the bus controller's parent controller. If the bus controller is a *Host Bus Controller*, then it will not have a parent controller. Nodes A, B, C, D, and E represent the child controllers of the bus controller.

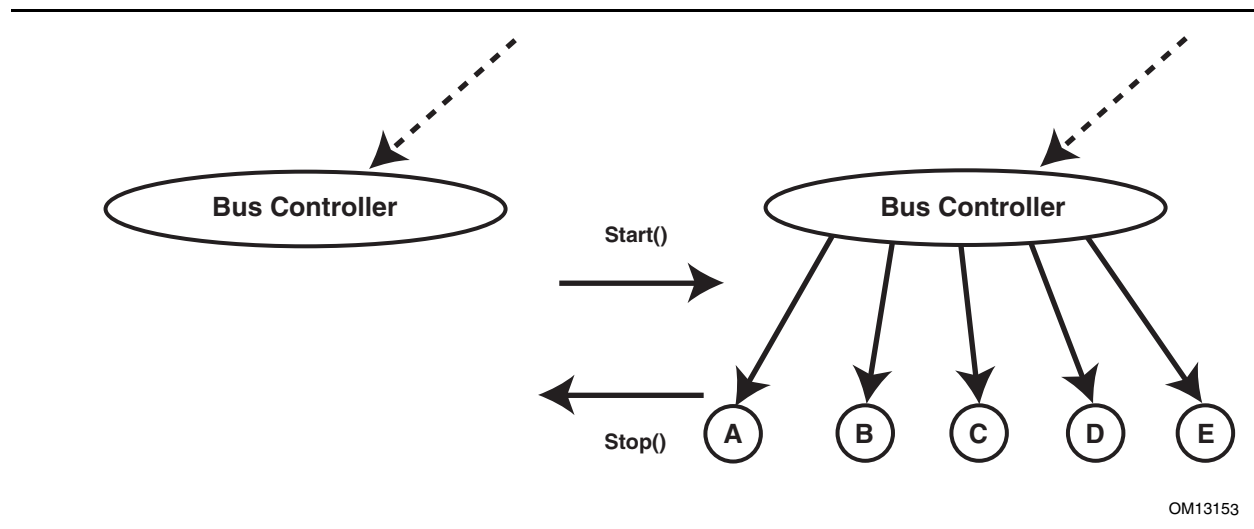

Figure 13. Connecting Bus Drivers

A bus driver that supports creating one child on each call to **Start()** might choose to create child C first, and then child E, and then the remaining children A, B, and D. The **Supported()**, **Start()**, and **Stop()** functions of the Driver Binding Protocol are flexible enough to allow this type of behavior.

A bus driver must install protocol interfaces onto every child handle that it creates. At a minimum, it must install a protocol interface that provides an I/O abstraction of the bus's services to the child controllers. If the bus driver creates a child handle that represents a physical device, then the bus driver must also install a Device Path Protocol instance onto the child handle. A bus driver may optionally install a Bus Specific Driver Override Protocol onto each child handle. This protocol is used when drivers are connected to the child controllers. The boot service [EFI_BOOT_SERVICES.ConnectController\(\)](#) uses architecturally defined precedence rules to choose the best set of drivers for a given controller. The Bus Specific Driver Override Protocol has higher precedence than a general driver search algorithm, and lower precedence than platform overrides. An example of a bus specific driver selection occurs with PCI. A PCI Bus Driver gives a driver stored in a PCI controller's option ROM a higher precedence than drivers stored elsewhere in the platform. [Figure 14](#) shows an example child device handle that was created by the XYZ Bus Driver that supports a bus specific driver override mechanism.

Figure 14. Child Device Handle with a Bus Specific Override

2.5.6 Platform Components

Under the *UEFI Driver Model*, the act of connecting and disconnecting drivers from controllers in a platform is under the platform firmware's control. This will typically be implemented as part of the UEFI Boot Manager, but other implementations are possible. The boot services

[`EFI_BOOT_SERVICES.ConnectController\(\)`](#) and [`EFI_BOOT_SERVICES.DisconnectController\(\)`](#) can be used by the platform firmware to determine which controllers get started and which ones do not. If the platform wishes to perform system diagnostics or install an operating system, then it may choose to connect drivers to all possible boot devices. If a platform wishes to boot a preinstalled operating system, it may choose to only connect drivers to the devices that are required to boot the selected operating system. The *UEFI Driver Model* supports both these modes of operation through the boot services

`ConnectController()` and `DisconnectController()`. In addition, since the platform component that is in charge of booting the platform has to work with device paths for console devices and boot options, all of the services and protocols involved in the *UEFI Driver Model* are optimized with device paths in mind.

Since the platform firmware may choose to only connect the devices required to produce consoles and gain access to a boot device, the OS present device drivers cannot assume that a UEFI driver for a device has been executed. The presence of a UEFI driver in the system firmware or in an option ROM does not guarantee that the UEFI driver will be loaded, executed, or allowed to manage any devices in a platform. All OS present device drivers must be able to handle devices that have been managed by a UEFI driver and devices that have not been managed by a UEFI driver.

The platform may also choose to produce a protocol named the Platform Driver Override Protocol. This is similar to the Bus Specific Driver Override Protocol, but it has higher priority. This gives the platform firmware the highest priority when deciding which drivers are connected to which controllers. The Platform Driver Override Protocol is attached to a handle in the system. The boot service `ConnectController()` will make use of this protocol if it is present in the system.

2.5.7 Hot-Plug Events

In the past, system firmware has not had to deal with hot-plug events in the preboot environment. However, with the advent of buses like USB, where the end user can add and remove devices at any time, it is important to make sure that it is possible to describe these types of buses in the UEFI *Driver Model*. It is up to the bus driver of a bus that supports the hot adding and removing of devices to provide support for such events. For these types of buses, some of the platform management is going to have to move into the bus drivers. For example, when a keyboard is hot added to a USB bus on a platform, the end user would expect the keyboard to be active. A USB Bus driver could detect the hot-add event and create a child handle for the keyboard device. However, because drivers are not connected to controllers unless [EFI_BOOT_SERVICES.ConnectController\(\)](#) is called, the keyboard would not become an active input device. Making the keyboard driver active requires the USB Bus driver to call **ConnectController()** when a hot-add event occurs. In addition, the USB Bus Driver would have to call [EFI_BOOT_SERVICES.DisconnectController\(\)](#) when a hot-remove event occurs. If [EFI_BOOT_SERVICES.DisconnectController\(\)](#) returns an error the USB Bus Driver needs to retry the [EFI_BOOT_SERVICES.DisconnectController\(\)](#) from a timer event until it succeeds.

Device drivers are also affected by these hot-plug events. In the case of USB, a device can be removed without any notice. This means that the **Stop()** functions of USB device drivers will have to deal with shutting down a driver for a device that is no longer present in the system. As a result, any outstanding I/O requests will have to be flushed without actually being able to touch the device hardware.

In general, adding support for hot-plug events greatly increases the complexity of both bus drivers and device drivers. Adding this support is up to the driver writer, so the extra complexity and size of the driver will need to be weighed against the need for the feature in the preboot environment.

2.5.8 EFI Services Binding

The UEFI *Driver Model* maps well onto hardware devices, hardware bus controllers, and simple combinations of software services that layer on top of hardware devices. However, the UEFI driver Model does not map well onto complex combinations of software services. As a result, an additional set of complementary protocols are required for more complex combinations of software services.

[Figure 15](#) contains three examples showing the different ways that software services relate to each other. In the first two cases, each service consumes one or more other services, and at most one other service consumes all of the services. Case #3 differs because two different services consume service A. The **EFI_DRIVER_BINDING_PROTOCOL** can be used to model cases #1 and #2, but it cannot be used to model case #3 because of the way that the UEFI Boot Service **OpenProtocol()** behaves. When used with the **BY_DRIVER** open mode, **OpenProtocol()** allows each protocol to have only at most one consumer. This feature is very useful and prevents multiple drivers from attempting to manage the same controller. However, it makes it difficult to produce sets of software services that look like case #3.

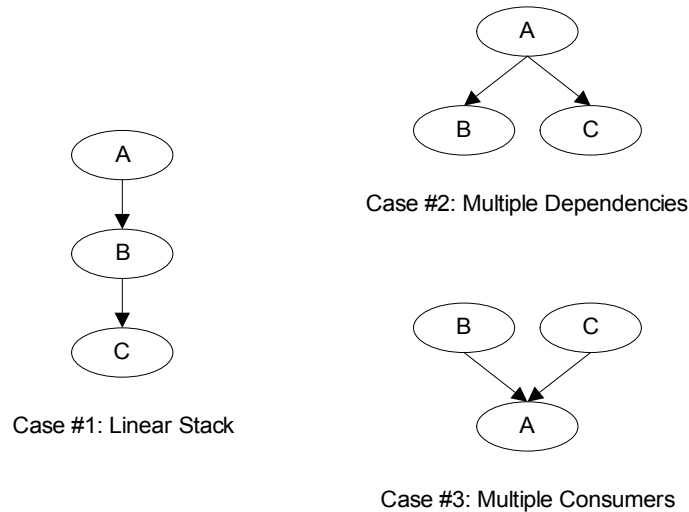

Figure 15. Software Service Relationships

The **EFI_SERVICE_BINDING_PROTOCOL** provides the mechanism that allows protocols to have more than one consumer. The **EFI_SERVICE_BINDING_PROTOCOL** is used with the **EFI_DRIVER_BINDING_PROTOCOL**. A UEFI driver that produces protocols that need to be available to more than one consumer at the same time will produce both the **EFI_DRIVER_BINDING_PROTOCOL** and the **EFI_SERVICE_BINDING_PROTOCOL**. This type of driver is a hybrid driver that will produce the **EFI_DRIVER_BINDING_PROTOCOL** in its driver entry point.

When the driver receives a request to start managing a controller, it will produce the **EFI_SERVICE_BINDING_PROTOCOL** on the handle of the controller that is being started. The **EFI_SERVICE_BINDING_PROTOCOL** is slightly different from other protocols defined in the *UEFI Specification*. It does not have a GUID associated with it. Instead, this protocol instance structure actually represents a family of protocols. Each software service driver that requires an **EFI_SERVICE_BINDING_PROTOCOL** instance will be required to generate a new GUID for its own type of **EFI_SERVICE_BINDING_PROTOCOL**. This requirement is why the various network protocols in this specification contain two GUIDs. One is the **EFI_SERVICE_BINDING_PROTOCOL** GUID for that network protocol, and the other GUID is for the protocol that contains the specific member services produced by the network driver. The mechanism defined here is not limited to network protocol drivers. It can be applied to any set of protocols that the **EFI_DRIVER_BINDING_PROTOCOL** cannot directly map because the protocols contain one or more relationships like case #3 in [Figure 15](#).

Neither the **EFI_DRIVER_BINDING_PROTOCOL** nor the combination of the **EFI_DRIVER_BINDING_PROTOCOL** and the **EFI_SERVICE_BINDING_PROTOCOL** can handle circular dependencies. There are methods to allow circular references, but they require that the circular link be present for short periods of time. When the protocols across the circular link are used, these methods also require that the protocol must be opened with an open mode of **EXCLUSIVE**, so that any attempts to deconstruct the set of protocols with a call to

DisconnectController() will fail. As soon as the driver is finished with the protocol across the circular link, the protocol should be closed.

2.6 Requirements

This document is an architectural specification. As such, care has been taken to specify architecture in ways that allow maximum flexibility in implementation. However, there are certain requirements on which elements of this specification must be implemented to ensure that operating system loaders and other code designed to run with UEFI boot services can rely upon a consistent environment.

For the purposes of describing these requirements, the specification is broken up into required and optional elements. In general, an optional element is completely defined in the section that matches the element name. For required elements however, the definition may in a few cases not be entirely self contained in the section that is named for the particular element. In implementing required elements, care should be taken to cover all the semantics defined in this specification that relate to the particular element.

2.6.1 Required Elements

[Table 10](#) lists the required elements. Any system that is designed to conform to this specification *must* provide a complete implementation of all these elements. This means that all the required service functions and protocols must be present and the implementation must deliver the full semantics defined in the specification for all combinations of calls and parameters. Implementers of applications, drivers or operating system loaders that are designed to run on a broad range of systems conforming to the UEFI specification may assume that all such systems implement all the required elements.

A system vendor may choose not to implement all the required elements, for example on specialized system configurations that do not support all the services and functionality implied by the required elements. However, since most applications, drivers and operating system loaders are written assuming all the required elements are present on a system that implements the UEFI specification; any such code is likely to require explicit customization to run on a less than complete implementation of the required elements in this specification.

Table 10. Required UEFI Implementation Elements

Element	Description
EFI SYSTEM TABLE	Provides access to UEFI Boot Services, UEFI Runtime Services, consoles, firmware vendor information, and the system configuration tables.
EFI BOOT SERVICES	All functions defined as boot services.
EFI RUNTIME SERVICES	All functions defined as runtime services.
EFI LOADED IMAGE PROTOCOL	Provides information on the image.
EFI LOADED IMAGE DEVICE PATH PROTOCOL	Specifies the device path that was used when a PE/COFF image was loaded through the EFI Boot Service LoadImage().
EFI DEVICE PATH PROTOCOL	Provides the location of the device.

Element	Description
EFI DECOMPRESS PROTOCOL	Protocol interfaces to decompress an image that was compressed using the EFI Compression Algorithm.
EFI DEVICE PATH UTILITIES PROTOCOL	Protocol interfaces to create and manipulate UEFI device paths and UEFI device path nodes.

2.6.2 Platform-Specific Elements

There are a number of elements that can be added or removed depending on the specific features that a platform requires. Platform firmware developers are required to implement UEFI elements based upon the features included. The following is a list of potential platform features and the elements that are required for each feature type:

1. If a platform includes console devices, the [EFI SIMPLE TEXT INPUT PROTOCOL](#), [EFI SIMPLE TEXT INPUT EX PROTOCOL](#), and [EFI SIMPLE TEXT OUTPUT PROTOCOL](#) must be implemented.
2. If a platform includes a configuration infrastructure, then the [EFI HII DATABASE PROTOCOL](#), [EFI HII STRING PROTOCOL](#), [EFI HII CONFIG ROUTING PROTOCOL](#), and [EFI HII CONFIG ACCESS PROTOCOL](#) are required. If you support bitmapped fonts, you must support [EFI HII FONT PROTOCOL](#).
3. If a platform includes graphical console devices, then the [EFI GRAPHICS OUTPUT PROTOCOL](#), [EFI EDID DISCOVERED PROTOCOL](#), and [EFI EDID ACTIVE PROTOCOL](#) must be implemented. In order to support the [EFI GRAPHICS OUTPUT PROTOCOL](#), a platform must contain a driver to consume [EFI GRAPHICS OUTPUT PROTOCOL](#) and produce [EFI SIMPLE TEXT OUTPUT PROTOCOL](#) even if the [EFI GRAPHICS OUTPUT PROTOCOL](#) is produced by an external driver.
4. If a platform includes a pointer device as part of its console support, the [EFI SIMPLE POINTER PROTOCOL](#) must be implemented.
5. If a platform includes the ability to boot from a disk device, then the [EFI BLOCK IO PROTOCOL](#), the [EFI DISK IO PROTOCOL](#), the [EFI SIMPLE FILE SYSTEM PROTOCOL](#), and the [EFI UNICODE COLLATION PROTOCOL](#) are required. In addition, partition support for MBR, GPT, and El Torito must be implemented. For disk devices supporting the security commands of the SPC-4 or ATA8-ACS command set, the [EFI STORAGE SECURITY COMMAND PROTOCOL](#) is also required. An external driver may produce the Block I/O Protocol and the [EFI STORAGE SECURITY COMMAND PROTOCOL](#). All other protocols required to boot from a disk device must be carried as part of the platform.
6. If a platform includes the ability to perform a TFTP-based boot from a network device, then the [EFI PXE BASE CODE PROTOCOL](#) is required. The platform must be prepared to produce this protocol on any of [EFI NETWORK INTERFACE IDENTIFIER PROTOCOL](#) (UNDI), [EFI SIMPLE NETWORK PROTOCOL](#), or the [EFI MANAGED NETWORK PROTOCOL](#). If a platform includes the ability to validate a boot image received through a network device, it is also required that image verification be supported, including *SetupMode* equal zero and the boot image hash or a verification certificate corresponding to the image exist in the 'db' variable and not in the 'dbx' variable. An external driver may produce the UEFI interface. All other protocols required to boot from a network device must be carried by the platform.

7. If a platform supports UEFI general purpose network applications, then the [EFI MANAGED NETWORK PROTOCOL](#), [EFI MANAGED NETWORK SERVICE BINDING PROTOCOL](#), [EFI ARP PROTOCOL](#), [EFI ARP SERVICE BINDING PROTOCOL](#), [EFI DHCP4 PROTOCOL](#), [EFI DHCP4 SERVICE BINDING PROTOCOL](#), [EFI TCP4 PROTOCOL](#), [EFI TCP4 SERVICE BINDING PROTOCOL](#), [IP4 Protocol](#), [EFI IP4 SERVICE BINDING PROTOCOL](#), [EFI IP4 CONFIG2 PROTOCOL](#), [EFI UDP4 PROTOCOL](#), and [EFI UDP4 SERVICE BINDING PROTOCOL](#) are required. If additional IPv6 support is needed for the platform, then [EFI DHCP6 PROTOCOL](#), [EFI DHCP6 SERVICE BINDING PROTOCOL](#), [EFI TCP6 PROTOCOL](#), [EFI TCP6 SERVICE BINDING PROTOCOL](#), [EFI IP6 PROTOCOL](#), [EFI IP6 SERVICE BINDING PROTOCOL](#), [EFI IP6 CONFIG PROTOCOL](#), [EFI UDP6 PROTOCOL](#), and [EFI UDP6 SERVICE BINDING PROTOCOL](#) are additionally required. If the network application requires DNS capability, [EFI DNS4 SERVICE BINDING PROTOCOL](#) and [EFI DNS4 PROTOCOL](#) are required for the IPv4 stack. [EFI DNS6 SERVICE BINDING PROTOCOL](#) and [EFI DNS6 PROTOCOL](#) are required for the IPv6 stack. If the network environment requires TLS features, [EFI TLS SERVICE BINDING PROTOCOL](#), [EFI TLS PROTOCOL](#) and [EFI TLS CONFIGURATION PROTOCOL](#) are required. If the network environment requires IPSEC feature, [EFI IPSEC CONFIG PROTOCOL](#) and [EFI IPSEC2 PROTOCOL](#) are required. If the network environment requires VLAN features, [EFI VLAN CONFIG PROTOCOL](#) is required.
8. If a platform includes a byte-stream device such as a UART, then the [EFI SERIAL IO PROTOCOL](#) must be implemented.
9. If a platform includes PCI bus support, then the [EFI PCI ROOT BRIDGE IO PROTOCOL](#), the [EFI PCI IO PROTOCOL](#), must be implemented.
10. If a platform includes USB bus support, then the [EFI USB2 HC PROTOCOL](#) and the [EFI USB IO PROTOCOL](#) must be implemented. An external device can support USB by producing a USB Host Controller Protocol.
11. . If a platform includes an NVM Express controller, then the [EFI NVM EXPRESS PASS THRU PROTOCOL](#) must be implemented.
12. If a platform supports booting from a block-oriented NVM Express controller, then the [EFI BLOCK IO PROTOCOL](#) must be implemented. An external driver may produce the [EFI NVM EXPRESS PASS THRU PROTOCOL](#) . All other protocols required to boot from an NVM Express subsystem must be carried by the platform.
13. If a platform includes an I/O subsystem that utilizes SCSI command packets, then the [EFI EXT SCSI PASS THRU PROTOCOL](#) must be implemented.
14. If a platform supports booting from a block oriented SCSI peripheral, then the [EFI SCSI IO PROTOCOL](#) and [EFI BLOCK IO PROTOCOL](#) must be implemented. An external driver may produce the [EFI EXT SCSI PASS THRU PROTOCOL](#). All other protocols required to boot from a SCSI I/O subsystem must be carried by the platform.
15. If a platform supports booting from an iSCSI peripheral, then the [EFI ISCSI INITIATOR NAME PROTOCOL](#) and the [EFI AUTHENTICATION INFO PROTOCOL](#) must be implemented.
16. If a platform includes debugging capabilities, then the [EFI DEBUG SUPPORT PROTOCOL](#), the [EFI DEBUGPORT PROTOCOL](#), and the [EFI Image Info](#) Table must be implemented.

17. If a platform includes the ability to override the default driver to the controller matching algorithm provided by the UEFI Driver Model, then the [EFI PLATFORM DRIVER OVERRIDE PROTOCOL](#) must be implemented.
18. If a platform includes an I/O subsystem that utilizes ATA command packets, then the [EFI ATA PASS THRU PROTOCOL](#) must be implemented.
19. If a platform supports option ROMs from devices not permanently attached to the platform and it supports the ability to authenticate those option ROMs, then it must support the option ROM validation methods described in [Network Protocols — UDP and MFTTP](#) and the authenticated EFI variables described in [Section 7.2](#).
20. If a platform includes the ability to authenticate UEFI images and the platform potentially supports more than one OS loader, it must support the methods described in [Network Protocols — UDP and MFTTP](#) and the authenticated UEFI variables described in [Section 7.2](#).
21. If a platform policy supports the inclusion or addition of any device that provides a container for one or more UEFI Drivers that are required for initialization of that device then an EBC interpreter must be implemented. If an EBC interpreter is implemented, then it must produce the [EFI EBC PROTOCOL](#) interface.
22. If a platform includes the ability to perform a HTTP-based boot from a network device, then the [EFI HTTP SERVICE BINDING PROTOCOL](#), [EFI HTTP PROTOCOL](#) and [EFI HTTP UTILITIES PROTOCOL](#) are required. If it includes the ability to perform a HTTPS-based boot from network device, besides above protocols, [EFI TLS SERVICE BINDING PROTOCOL](#), [EFI TLS PROTOCOL](#) and [EFI TLS CONFIGURATION PROTOCOL](#) are also required. If it includes the ability to perform a HTTP(S)-based boot with DNS feature, then [EFI DNS4 SERVICE BINDING PROTOCOL](#), [EFI DNS4 PROTOCOL](#) are required for the IPv4 stack; [EFI DNS6 SERVICE BINDING PROTOCOL](#) and [EFI DNS6 PROTOCOL](#) are required for the IPv6 stack.
23. If a platform includes the ability to perform a wireless boot from a network device with EAP feature, and if this platform provides a standalone wireless EAP driver, then [EFI EAP PROTOCOL](#), [EFI EAP CONFIGURATION PROTOCOL](#), and [EFI EAP MANAGEMENT2 PROTOCOL](#) are required; if the platform provides a standalone wireless supplicant, then [EFI SUPPLICANT PROTOCOL](#) and [EFI EAP CONFIGURATION PROTOCOL](#) are required. If it includes the ability to perform a wireless boot with TLS feature, then [EFI TLS SERVICE BINDING PROTOCOL](#), [EFI TLS PROTOCOL](#) and [EFI TLS CONFIGURATION PROTOCOL](#) are required.
24. If a platform supports classic Bluetooth, then [EFI BLUETOOTH HC PROTOCOL](#), [EFI BLUETOOTH IO PROTOCOL](#), and [EFI BLUETOOTH CONFIG PROTOCOL](#) must be implemented. If a platform support Bluetooth Smart (Bluetooth Low Energy), then [EFI BLUETOOTH HC PROTOCOL](#), [EFI BLUETOOTH IO PROTOCOL](#) and [EFI BLUETOOTH CONFIG PROTOCOL](#) may be implemented.
25. 24. If a platform supports RESTful communication over HTTP or over an in-band path to a BMC, then the [EFI REST PROTOCOL](#) must be implemented.
26. If a platform includes the ability to use a hardware feature to create high quality random numbers, this capability should be exposed by instance of [EFI RNG PROTOCOL](#) with at least one EFI RNG Algorithm supported.
27. If a platform permits the installation of Load Option Variables, (Boot#####, or Driver#####, or SysPrep#####), the platform must support and recognize all defined values for Attributes within the variable and report these capabilities in BootOptionSupport. If a platform supports

installation of Load Option Variables of type Driver#####, all installed Driver##### variables must be processed and the indicated driver loaded and initialized during every boot. And all installed SysPrep##### options must be processed prior to processing Boot##### options.

28. If the platform supports UEFI secure boot as described in [Secure Boot and Driver Signing](#), the platform must provide the PKCS verification functions described in [Section 35.4](#).
29. If a platform includes an I/O subsystem that utilizes SD or eMMC command packets, then the [EFI SD MMC PASS THRU PROTOCOL](#) must be implemented.
30. If a platform includes the ability to create/destroy a specified RAM disk, the [EFI RAM DISK PROTOCOL](#) must be implemented and only one instance of this protocol exists.
31. If a platform includes a mass storage device which supports hardware-based erase on a specified range, then the [EFI ERASE BLOCK PROTOCOL](#) must be implemented.

2.6.3 Driver-Specific Elements

There are a number of UEFI elements that can be added or removed depending on the features that a specific driver requires. Drivers can be implemented by platform firmware developers to support buses and devices in a specific platform. Drivers can also be implemented by add-in card vendors for devices that might be integrated into the platform hardware or added to a platform through an expansion slot.

The following list includes possible driver features, and the UEFI elements that are required for each feature type:

1. If a driver follows the driver model of this specification, the [EFI DRIVER BINDING PROTOCOL](#) must be implemented. It is strongly recommended that all drivers that follow the driver model of this specification also implement the [EFI COMPONENT NAME2 PROTOCOL](#).
2. If a driver requires configuration information, the driver must use the [EFI HII DATABASE PROTOCOL](#). A driver should not otherwise display information to the user or request information from the user.
3. If a driver requires diagnostics, the [EFI DRIVER DIAGNOSTICS2 PROTOCOL](#) must be implemented. In order to support low boot times, limit diagnostics during normal boots. Time consuming diagnostics should be deferred until the [EFI DRIVER DIAGNOSTICS2 PROTOCOL](#) is invoked.
4. If a bus supports devices that are able to provide containers for drivers (e.g. option ROMs), then the bus driver for that bus type must implement the [EFI BUS SPECIFIC DRIVER OVERRIDE PROTOCOL](#).
5. If a driver is written for a console output device, then the [EFI SIMPLE TEXT OUTPUT PROTOCOL](#) must be implemented.
6. If a driver is written for a graphical console output device, then the [EFI GRAPHICS OUTPUT PROTOCOL](#), [EFI EDID DISCOVERED PROTOCOL](#) and [EFI EDID ACTIVE PROTOCOL](#) must be implemented.
7. If a driver is written for a console input device, then the [EFI SIMPLE TEXT INPUT PROTOCOL](#) and [EFI SIMPLE TEXT INPUT EX PROTOCOL](#) must be implemented.
8. If a driver is written for a pointer device, then the [EFI SIMPLE POINTER PROTOCOL](#) must be implemented.

9. If a driver is written for a network device, then the [EFI NETWORK INTERFACE IDENTIFIER PROTOCOL](#), [EFI SIMPLE NETWORK PROTOCOL](#) or [EFI MANAGED NETWORK PROTOCOL](#) must be implemented. If VLAN is supported in hardware, then driver for the network device may implement the [EFI VLAN CONFIG PROTOCOL](#). If a network device chooses to only produce the [EFI MANAGED NETWORK PROTOCOL](#), then the driver for the network device must implement the [EFI VLAN CONFIG PROTOCOL](#). If a driver is written for a network device to supply wireless feature, besides above protocols, [EFI ADAPTER INFORMATION PROTOCOL](#) must be implemented. If the wireless driver does not provide user configuration capability, [EFI WIRELESS MAC CONNECTION II PROTOCOL](#) must be implemented. If the wireless driver is written for a platform which provides a standalone wireless EAP driver, [EFI EAP PROTOCOL](#) must be implemented.
10. If a driver is written for a disk device, then the [EFI BLOCK IO PROTOCOL](#) and the [EFI BLOCK IO2 PROTOCOL](#) must be implemented. In addition, the [EFI STORAGE SECURITY COMMAND PROTOCOL](#) must be implemented for disk devices supporting the security commands of the SPC-4 or ATA8-ACS command set. In addition, for devices that support inline encryption in the host storage controller, the [EFI BLOCK IO CRYPTO PROTOCOL](#) must be supported.
11. If a driver is written for a disk device, then the [EFI BLOCK IO PROTOCOL](#) and the [EFI BLOCK IO2 PROTOCOL](#) must be implemented. In addition, the [EFI STORAGE SECURITY COMMAND PROTOCOL](#) must be implemented for disk devices supporting the security commands of the SPC-4 or ATA8-ACS command set.
12. If a driver is written for a device that is not a block oriented device but one that can provide a file system-like interface, then the [EFI SIMPLE FILE SYSTEM PROTOCOL](#) must be implemented.
13. If a driver is written for a PCI root bridge, then the [EFI PCI ROOT BRIDGE IO PROTOCOL](#) and the [EFI PCI IO PROTOCOL](#) must be implemented.
14. If a driver is written for an NVM Express controller, then the [EFI NVM EXPRESS PASS THRU PROTOCOL](#) must be implemented.
15. If a driver is written for a USB host controller, then the [EFI USB2 HC PROTOCOL](#) and the [EFI USB IO PROTOCOL](#) must be implemented. If a driver is written for a USB host controller, then the must be implemented.
16. If a driver is written for a SCSI controller, then the [EFI EXT SCSI PASS THRU PROTOCOL](#) must be implemented.
17. If a driver is digitally signed, it must embed the digital signature in the PE/COFF image as described in [“Embedded Signatures” on page 1810](#).
18. If a driver is written for a boot device that is not a block-oriented device, a file system-based device, or a console device, then the [EFI LOAD FILE PROTOCOL](#) must be implemented.
19. If a driver follows the driver model of this specification, and the driver wants to produce warning or error messages for the user, then the [EFI DRIVER HEALTH PROTOCOL](#) must be used to produce those messages. The Boot Manager may optionally display the messages to the user.
20. If a driver follows the driver model of this specification, and the driver needs to perform a repair operation that is not part of the normal initialization sequence, and that repair operation requires an extended period of time, then the [EFI DRIVER HEALTH PROTOCOL](#) must be used to

provide the repair feature. If the Boot Manager detects a boot device that requires a repair operation, then the Boot Manager must use the [EFI DRIVER HEALTH PROTOCOL](#) to perform the repair operation. The Boot Manager can optionally display progress indicators as the repair operation is performed by the driver.

21. If a driver follows the driver model of this specification, and the driver requires the user to make software and/or hardware configuration changes before the boot devices that the driver manages can be used, then the [EFI DRIVER HEALTH PROTOCOL](#) must be produced. If the Boot Manager detects a boot device that requires software and/or hardware configuration changes to make the boot device usable, then the Boot Manager may optionally allow the user to make those configuration changes.
22. If a driver is written for an ATA controller, then the [EFI ATA PASS THRU PROTOCOL](#) must be implemented.
23. If a driver follows the driver model of this specification, and the driver wants to be used with higher priority than the Bus Specific Driver Override Protocol when selecting the best driver for controller, then the [EFI DRIVER FAMILY OVERRIDE PROTOCOL](#) must be produced on the same handle as the [EFI DRIVER BINDING PROTOCOL](#).
24. If a driver supports firmware management by an external agent or application, then the [EFI FIRMWARE MANAGEMENT PROTOCOL](#) must be used to support firmware management.
25. If a driver follows the driver model of this specification and a driver is a device driver as defined in [Section 2.5](#), it must perform bus transactions via the bus abstraction protocol produced by a parent bus driver. Thus a driver for a device that conforms to the PCI specification must use [EFI PCI IO PROTOCOL](#) for all PCI memory space, PCI I/O, PCI configuration space, and DMA operations.
26. If a driver is written for a classic Bluetooth controller, then [EFI BLUETOOTH HC PROTOCOL](#), [EFI BLUETOOTH IO PROTOCOL](#) and [EFI BLUETOOTH CONFIG PROTOCOL](#) must be implemented. If a driver written for a Bluetooth Smart (Bluetooth Low Energy) controller, then [EFI BLUETOOTH HC PROTOCOL](#), [EFI BLUETOOTH IO PROTOCOL](#) and [EFI BLUETOOTH CONFIG PROTOCOL](#) may be implemented.
27. If a driver is written for an SD controller or eMMC controller, then the [EFI SD MMC PASS THRU PROTOCOL](#) must be implemented.

2.6.4 Extensions to this Specification published elsewhere

This specification has been extended over time to include support for new devices and technologies. As the name of the specification implies, the original intent in its definition was to create a baseline for firmware interfaces that is extensible without the need to include extensions in the main body of this specification.

Readers of this specification may find that a feature or type of device is not treated by the specification. This does not necessarily mean that there is no agreed "standard" way to support the feature or device in implementations that claim conformance to this Specification. On occasion, it may be more appropriate for other standards organizations to publish their own extensions that are designed to be used in concert with the definitions presented here. This may for example allow support for new features in a more timely fashion than would be accomplished by waiting for a revision to this specification or perhaps that such support is defined by a group with a specific expertise in the subject area. Readers looking for means to access features or devices that are not

treated in this document are therefore recommended to inquire of appropriate standards groups to ascertain if appropriate extension publications already exist before creating their own extensions.

By way of examples, at the time of writing the UEFI Forum is aware of a number of extension publications that are compatible with and designed for use with this specification. Such extensions include:

Developers Interface Guide for Itanium® Architecture Based Servers: published and hosted by the DIG64 group (See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “Developers Interface Guide for Itanium® Architecture Based Servers”). This document is a set of technical guidelines that define hardware, firmware, and operating system compatibility for Itanium™-based servers;

TCG EFI Platform Specification: published and hosted by the Trusted Computing Group (See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “TCG EFI Platform Specification”). This document is about the processes that boot an EFI platform and boot an OS on that platform. Specifically, this specification contains the requirements for measuring boot events into TPM PCRs and adding boot event entries into the Event Log.

TCG EFI Protocol Specification: published and hosted by the Trusted Computing Group (See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “TCG EFI Protocol Specification”). This document defines a standard interface to the TPM on an EFI platform.

Other extension documents may exist outside the view of the UEFI Forum or may have been created since the last revision of this document.

Boot Manager

The UEFI boot manager is a firmware policy engine that can be configured by modifying architecturally defined global NVRAM variables. The boot manager will attempt to load UEFI drivers and UEFI applications (including UEFI OS boot loaders) in an order defined by the global NVRAM variables. The platform firmware must use the boot order specified in the global NVRAM variables for normal boot. The platform firmware may add extra boot options or remove invalid boot options from the boot order list.

The platform firmware may also implement value added features in the boot manager if an exceptional condition is discovered in the firmware boot process. One example of a value added feature would be not loading a UEFI driver if booting failed the first time the driver was loaded. Another example would be booting to an OEM-defined diagnostic environment if a critical error was discovered in the boot process.

The boot sequence for UEFI consists of the following:

- The boot order list is read from a globally defined NVRAM variable. Modifications to this variable are only guaranteed to take effect after the next platform reset. The boot order list defines a list of NVRAM variables that contain information about what is to be booted. Each NVRAM variable defines a name for the boot option that can be displayed to a user.
- The variable also contains a pointer to the hardware device and to a file on that hardware device that contains the UEFI image to be loaded.
- The variable might also contain paths to the OS partition and directory along with other configuration specific directories.

The NVRAM can also contain load options that are passed directly to the UEFI image. The platform firmware has no knowledge of what is contained in the load options. The load options are set by higher level software when it writes to a global NVRAM variable to set the platform firmware boot policy. This information could be used to define the location of the OS kernel if it was different than the location of the UEFI OS loader.

3.1 Firmware Boot Manager

The boot manager is a component in firmware conforming to this specification that determines which drivers and applications should be explicitly loaded and when. Once compliant firmware is initialized, it passes control to the boot manager. The boot manager is then responsible for determining what to load and any interactions with the user that may be required to make such a decision.

The actions taken by the boot manager depend upon the system type and the policies set by the system designer. For systems that allow the installation of new Boot Variables ([Section 3.4](#)), the Boot Manager must automatically or upon the request of the loaded item, initialize at least one system console, as well as perform all required initialization of the device indicated within the

primary boot target. For such systems, the Boot Manager is also required to honor the priorities set in `BootOrder` variable.

In particular, likely implementation options might include any console interface concerning boot, integrated platform management of boot selections, and possible knowledge of other internal applications or recovery drivers that may be integrated into the system through the boot manager.

3.1.1 Boot Manager Programming

Programmatic interaction with the boot manager is accomplished through globally defined variables. On initialization the boot manager reads the values which comprise all of the published load options among the UEFI environment variables. By using the [SetVariable\(\)](#) function the data that contain these environment variables can be modified. Such modifications are guaranteed to take effect after the next system boot commences. However, boot manager implementations may choose to improve on this guarantee and have changes take immediate effect for all subsequent accesses to the variables that affect boot manager behavior without requiring any form of system reset

Each load option entry resides in a `Boot####`, `Driver####`, `SysPrep####`, `OsRecovery####` or `PlatformRecovery####` variable where `####` is replaced by a unique option number in printable hexadecimal representation using the digits 0–9, and the upper case versions of the characters A–F (0000–FFFF).

The `####` must always be four digits, so small numbers must use leading zeros. The load options are then logically ordered by an array of option numbers listed in the desired order. There are two such option ordering lists when booting normally. The first is `DriverOrder` that orders the `Driver####` load option variables into their load order. The second is `BootOrder` that orders the `Boot####` load options variables into their load order.

For example, to add a new boot option, a new `Boot####` variable would be added. Then the option number of the new `Boot####` variable would be added to the `BootOrder` ordered list and the `BootOrder` variable would be rewritten. To change boot option on an existing `Boot####`, only the `Boot####` variable would need to be rewritten. A similar operation would be done to add, remove, or modify the driver load list.

If the boot via `Boot####` returns with a status of `EFI_SUCCESS`, platform firmware supports boot manager menu, and if firmware is configured to boot in an interactive mode, the boot manager will stop processing the `BootOrder` variable and present a boot manager menu to the user. If any of the above-mentioned conditions is not satisfied, the next `Boot####` in the `BootOrder` variable will be tried until all possibilities are exhausted. In this case, boot option recovery must be performed (see [Section 3.4](#)).

The boot manager may perform automatic maintenance of the database variables. For example, it may remove unreferenced load option variables or any load option variables that cannot be parsed, and it may rewrite any ordered list to remove any load options that do not have corresponding load option variables. The boot manager can also, at its own discretion, provide an administrator with the ability to invoke manual maintenance operations as well. Examples include choosing the order of any or all load options, activating or deactivating load options, initiating OS-defined or platform-defined recovery, etc. In addition, if a platform intends to create `PlatformRecovery####`, before attempting to load and execute any `DriverOrder` or `BootOrder` entries, the firmware must create any and all `PlatformRecovery####` variables (see [Section 3.4.2](#)). The firmware should not, under normal operation, automatically remove any correctly formed `Boot####` variable

currently referenced by the *BootOrder* or *BootNext* variables. Such removal should be limited to scenarios where the firmware is guided by direct user interaction.

The contents of *PlatformRecovery####* represent the final recovery options the firmware would have attempted had recovery been initiated during the current boot, and need not include entries to reflect contingencies such as significant hardware reconfiguration, or entries corresponding to specific hardware that the firmware is not yet aware of.

The behavior of the UEFI Boot Manager is impacted when Secure Boot is enabled, See [Section 30.4](#).

3.1.2 Load Option Processing

The boot manager is required to process the Driver load option entries before the Boot load option entries. If the **EFI_OS_INDICATIONS_START_OS_RECOVERY** bit has been set in *OsIndications*, the firmware shall attempt OS-defined recovery (see [Section 3.4.1](#)) rather than normal boot processing. If the **EFI_OS_INDICATIONS_START_PLATFORM_RECOVERY** bit has been set in *OsIndications*, the firmware shall attempt platform-defined recovery (see [Section 3.4.2](#)) rather than normal boot processing or handling of the **EFI_OS_INDICATIONS_START_OS_RECOVERY** bit. In either case, both bits should be cleared.

Otherwise, the boot manager is also required to initiate a boot of the boot option specified by the *BootNext* variable as the first boot option on the next boot, and only on the next boot. The boot manager removes the *BootNext* variable before transferring control to the *BootNext* boot option. After the *BootNext* boot option is tried, the normal *BootOrder* list is used. To prevent loops, the boot manager deletes *BootNext* before transferring control to the preselected boot option.

If all entries of *BootNext* and *BootOrder* have been exhausted without success, or if the firmware has been instructed to attempt boot order recovery, the firmware must attempt boot option recovery (see [Section 3.4](#)).

The boot manager must call [EFI_BOOT_SERVICES.LoadImage\(\)](#) which supports at least [EFI_SIMPLE_FILE_SYSTEM_PROTOCOL](#) and [EFI_LOAD_FILE_PROTOCOL](#) for resolving load options. If [LoadImage\(\)](#) succeeds, the boot manager must enable the watchdog timer for 5 minutes by using the [EFI_BOOT_SERVICES.SetWatchdogTimer\(\)](#) boot service prior to calling [EFI_BOOT_SERVICES.StartImage\(\)](#). If a boot option returns control to the boot manager, the boot manager must disable the watchdog timer with an additional call to the [SetWatchdogTimer\(\)](#) boot service.

If the boot image is not loaded via [EFI_BOOT_SERVICES.LoadImage\(\)](#) the boot manager is required to check for a default application to boot. Searching for a default application to boot happens on both removable and fixed media types. This search occurs when the device path of the boot image listed in any boot option points directly to an **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL** device and does not specify the exact file to load. The file discovery method is explained in [Section 3.4](#). The default media boot case of a protocol other than **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL** is handled by the [EFI_LOAD_FILE_PROTOCOL](#) for the target device path and does not need to be handled by the boot manager.

The UEFI boot manager must support booting from a short-form device path that starts with the first element being a USB WWID (see [Table 62](#)) or a USB Class (see [Table 64](#)) device path. For USB WWID, the boot manager must use the device vendor ID, device product id, and serial number, and

must match any USB device in the system that contains this information. If more than one device matches the USB WWID device path, the boot manager will pick one arbitrarily. For USB Class, the boot manager must use the vendor ID, Product ID, Device Class, Device Subclass, and Device Protocol, and must match any USB device in the system that contains this information. If any of the ID, Product ID, Device Class, Device Subclass, or Device Protocol contain all F's (0xFFFF or 0xFF), this element is skipped for the purpose of matching. If more than one device matches the USB Class device path, the boot manager will pick one arbitrarily.

The boot manager must also support booting from a short-form device path that starts with the first element being a hard drive media device path (see [Table 85](#)). The boot manager must use the GUID or signature and partition number in the hard drive device path to match it to a device in the system. If the drive supports the GPT partitioning scheme the GUID in the hard drive media device path is compared with the *UniquePartitionGuid* field of the GUID Partition Entry (see [Table 19](#)). If the drive supports the PC-AT MBR scheme the signature in the hard drive media device path is compared with the *UniqueMBRSignature* in the Legacy Master Boot Record (see [Table 14](#)). If a signature match is made, then the partition number must also be matched. The hard drive device path can be appended to the matching hardware device path and normal boot behavior can then be used. If more than one device matches the hard drive device path, the boot manager will pick one arbitrarily. Thus the operating system must ensure the uniqueness of the signatures on hard drives to guarantee deterministic boot behavior.

The boot manager must also support booting from a short-form device path that starts with the first element being a File Path Media Device Path (see [Table 88](#)). When the boot manager attempts to boot a short-form File Path Media Device Path, it will enumerate all removable media devices, followed by all fixed media devices, creating boot options for each device. The boot option `FilePathList[0]` is constructed by appending short-form File Path Media Device Path to the device path of a media. The order within each group is undefined. These new boot options must not be saved to non volatile storage, and may not be added to *BootOrder*. The boot manager will then attempt to boot from each boot option. If a device does not support the **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL**, but supports the **EFI_BLOCK_IO_PROTOCOL** protocol, then the EFI Boot Service *ConnectController* must be called for this device with *DriverImageHandle* and *RemainingDevicePath* set to NULL and the Recursive flag is set to **TRUE**. The firmware will then attempt to boot from any child handles produced using the algorithms outlined above.

The boot manager must also support booting from a short-form device path that starts with the first element being a URI Device Path (see [Table 79](#)). When the boot manager attempts to boot a short-form URI Device Path, it could attempt to connect any device which will produce a device path protocol including a URI device path node until it matches a device, or fail to match any device. The boot manager will enumerate all *LoadFile* protocol instances, and invoke *LoadFile* protocol with *FilePath* set to the short-form device path during the matching process.

3.1.3 Load Options

Each load option variable contains an **EFI_LOAD_OPTION** descriptor that is a byte packed buffer of variable length fields.

```
typedef struct _EFI_LOAD_OPTION {
    UINT32                Attributes;
    UINT16                FilePathListLength;
```

```

// CHAR16                Description[];
// EFI_DEVICE_PATH_PROTOCOL FilePathList[];
// UINT8                 OptionalData[];
} EFI_LOAD_OPTION;

```

Parameters

<i>Attributes</i>	The attributes for this load option entry. All unused bits must be zero and are reserved by the UEFI specification for future growth. See “Related Definitions.”
<i>FilePathListLength</i>	Length in bytes of the <i>FilePathList</i> . <i>OptionalData</i> starts at offset sizeof(UINT32) + sizeof(UINT16) + StrSize(Description) + FilePathListLength of the EFI_LOAD_OPTION descriptor.
<i>Description</i>	The user readable description for the load option. This field ends with a Null character.
<i>FilePathList</i>	A packed array of UEFI device paths. The first element of the array is a device path that describes the device and location of the Image for this load option. The <i>FilePathList[0]</i> is specific to the device type. Other device paths may optionally exist in the <i>FilePathList</i> , but their usage is OSV specific. Each element in the array is variable length, and ends at the device path end structure. Because the size of <i>Description</i> is arbitrary, this data structure is not guaranteed to be aligned on a natural boundary. This data structure may have to be copied to an aligned natural boundary before it is used.
<i>OptionalData</i>	The remaining bytes in the load option descriptor are a binary data buffer that is passed to the loaded image. If the field is zero bytes long, a NULL pointer is passed to the loaded image. The number of bytes in <i>OptionalData</i> can be computed by subtracting the starting offset of <i>OptionalData</i> from total size in bytes of the EFI_LOAD_OPTION .

Related Definitions

```

//*****
// Attributes
//*****
#define LOAD_OPTION_ACTIVE           0x00000001
#define LOAD_OPTION_FORCE_RECONNECT 0x00000002
#define LOAD_OPTION_HIDDEN          0x00000008
#define LOAD_OPTION_CATEGORY        0x00001F00

#define LOAD_OPTION_CATEGORY_BOOT   0x00000000
#define LOAD_OPTION_CATEGORY_APP    0x00000100
// All values 0x00000200-0x00001F00 are reserved

```

Description

Calling [SetVariable\(\)](#) creates a load option. The size of the load option is the same as the size of the *DataSize* argument to the **SetVariable()** call that created the variable. When creating a new load option, all undefined attribute bits must be written as zero. When updating a load option, all undefined attribute bits must be preserved.

If a load option is marked as **LOAD_OPTION_ACTIVE**, the boot manager will attempt to boot automatically using the device path information in the load option. This provides an easy way to disable or enable load options without needing to delete and re-add them.

If any *Driver####* load option is marked as **LOAD_OPTION_FORCE_RECONNECT**, then all of the UEFI drivers in the system will be disconnected and reconnected after the last *Driver####* load option is processed. This allows a UEFI driver loaded with a *Driver####* load option to override a UEFI driver that was loaded prior to the execution of the UEFI Boot Manager.

The executable indicated by *FilePathList[0]* in *Driver####* load option must be of type **EFI_IMAGE_SUBSYSTEM_EFI_BOOT_SERVICE_DRIVER** or **EFI_IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER** otherwise the indicated executable will not be entered for initialization.

The executable indicated by *FilePathList[0]* in *SysPrep###*, *Boot####*, or *OsRecovery####* load option must be of type **EFI_IMAGE_SUBSYSTEM_EFI_APPLICATION**, otherwise the indicated executable will not be entered.

The **LOAD_OPTION_CATEGORY** is a sub-field of Attributes that provides details to the boot manager to describe how it should group the *Boot####* load options. This field is ignored for variables of the form *Driver####*, *SysPrep####*, or *OsRecovery####*.

Boot#### load options with **LOAD_OPTION_CATEGORY** set to **LOAD_OPTION_CATEGORY_BOOT** are meant to be part of the normal boot processing.

Boot#### load options with **LOAD_OPTION_CATEGORY** set to **LOAD_OPTION_CATEGORY_APP** are executables which are not part of the normal boot processing but can be optionally chosen for execution if boot menu is provided, or via Hot Keys. See [Section 3.1.6](#) for details.

Boot options with reserved category values, will be ignored by the boot manager.

If any *Boot####* load option is marked as **LOAD_OPTION_HIDDEN**, then the load option will not appear in the menu (if any) provided by the boot manager for load option selection.

3.1.4 Boot Manager Capabilities

The boot manager can report its capabilities through the global variable *BootOptionSupport*. If the global variable is not present, then an installer or application must act as if a value of 0 was returned.

```
#define EFI_BOOT_OPTION_SUPPORT_KEY      0x00000001
#define EFI_BOOT_OPTION_SUPPORT_APP     0x00000002
#define EFI_BOOT_OPTION_SUPPORT_SYSPREP 0x00000010
#define EFI_BOOT_OPTION_SUPPORT_COUNT   0x00000300
```

If **EFI_BOOT_OPTION_SUPPORT_KEY** is set then the boot manager supports launching of *Boot####* load options using key presses. If **EFI_BOOT_OPTION_SUPPORT_APP** is set then

the boot manager supports boot options with **LOAD_OPTION_CATEGORY_APP**. If **EFI_BOOT_OPTION_SUPPORT_SYSPREP** is set then the boot manager supports boot options of form *SysPrep####*.

The value specified in **EFI_BOOT_OPTION_SUPPORT_COUNT** describes the maximum number of key presses which the boot manager supports in the **EFI_KEY_OPTION.KeyData.InputKeyCount**. This value is only valid if **EFI_BOOT_OPTION_SUPPORT_KEY** is set. Key sequences with more keys specified are ignored.

3.1.5 Launching Boot#### Applications

The boot manager may support a separate category of *Boot####* load option for applications. The boot manager indicates that it supports this separate category by setting the **EFI_BOOT_OPTION_SUPPORT_APP** in the *BootOptionSupport* global variable.

When an application's *Boot####* option is being added to the *BootOrder*, the installer should clear **LOAD_OPTION_ACTIVE** so that the boot manager does not attempt to automatically “boot” the application. If the boot manager indicates that it supports a separate application category, as described above, the installer should set **LOAD_OPTION_CATEGORY_APP**. If not, it should set **LOAD_OPTION_CATEGORY_BOOT**.

3.1.6 Launching Boot#### Load Options Using Hot Keys

The boot manager may support launching a *Boot####* load option using a special key press. If so, the boot manager reports this capability by setting **EFI_BOOT_OPTION_SUPPORT_KEY** in the *BootOptionSupport* global variable.

A boot manager which supports key press launch reads the current key information from the console. Then, if there was a key press, it compares the key returned against zero or more *Key####* global variables. If it finds a match, it verifies that the *Boot####* load option specified is valid and, if so, attempts to launch it immediately. The ##### in the *Key####* is a printable hexadecimal number ('0'-'9', 'A'-'F') with leading zeroes. The order which the *Key####* variables are checked is implementation-specific.

The boot manager may ignore *Key####* variables where the hot keys specified overlap with those used for internal boot manager functions. It is recommended that the boot manager delete these keys.

The *Key####* variables have the following format:

Prototype

```
typedef struct _EFI_KEY_OPTION {
    EFI_BOOT_KEY_DATA    KeyData;
    UINT32               BootOptionCrc;
    UINT16               BootOption;
    // EFI_INPUT_KEY     Keys[];
} EFI_KEY_OPTION;
```

Parameters

KeyData

Specifies options about how the key will be processed. Type **EFI_BOOT_KEY_DATA** is defined in “Related Definitions” below.

BootOptionCrc

The CRC-32 which should match the CRC-32 of the entire **EFI_LOAD_OPTION** to which *BootOption* refers. If the CRC-32s do not match this value, then this key option is ignored.

BootOption

The Boot#### option which will be invoked if this key is pressed and the boot option is active (**LOAD_OPTION_ACTIVE** is set).

Keys

The key codes to compare against those returned by the **EFI_SIMPLE_TEXT_INPUT** and **EFI_SIMPLE_TEXT_INPUT_EX** protocols. The number of key codes (0-3) is specified by the **EFI_KEY_CODE_COUNT** field in *KeyOptions*.

Related Definitions

```
typedef union {
    struct {
        UINT32 Revision : 8;
        UINT32 ShiftPressed : 1;
        UINT32 ControlPressed : 1;
        UINT32 AltPressed : 1;
        UINT32 LogoPressed : 1;
        UINT32 MenuPressed : 1;
        UINT32 SysReqPressed : 1;
        UINT32 Reserved : 16;
        UINT32 InputKeyCount : 2;
    } Options;
    UINT32 PackedValue;
} EFI_BOOT_KEY_DATA;
```

Revision

Indicates the revision of the **EFI_KEY_OPTION** structure. This revision level should be 0.

ShiftPressed

Either the left or right Shift keys must be pressed (1) or must not be pressed (0).

ControlPressed

Either the left or right Control keys must be pressed (1) or must not be pressed (0).

AltPressed

Either the left or right Alt keys must be pressed (1) or must not be pressed (0).

LogoPressed

Either the left or right Logo keys must be pressed (1) or must not be pressed (0).

MenuPressed

The Menu key must be pressed (1) or must not be pressed (0).

SysReqPressed

The SysReq key must be pressed (1) or must not be pressed (0).

InputKeyCount

Specifies the actual number of entries in **EFI_KEY_OPTION.Keys**, from 0-3. If zero, then only the shift state is considered. If more than one, then the boot option will only be launched if all of the specified keys are pressed with the same shift state.

Example #1: ALT is the hot key. *KeyData.PackedValue* = **0x00000400**.

Example #2: CTRL-ALT-P-R. *KeyData.PackedValue* = **0x80000600**.

Example #3: CTRL-F1. *KeyData.PackedValue* = **0x40000200**.

3.1.7 Required System Preparation Applications

A load option of the form *SysPrep####* is intended to designate a UEFI application that is required to execute in order to complete system preparation prior to processing of any *Boot####* variables. The execution order of *SysPrep####* applications is determined by the contents of the variable *SysPrepOrder* in a way directly analogous to the ordering of *Boot####* options by *BootOrder*.

The platform is required to examine all *SysPrep####* variables referenced in *SysPrepOrder*. If Attributes bit **LOAD_OPTION_ACTIVE** is set, and the application referenced by *FilePathList[0]* is present, the UEFI Applications thus identified must be loaded and launched in the order they appear in *SysPrepOrder* and prior to the launch of any load options of type *Boot####*.

When launched, the platform is required to provide the application loaded by *SysPrep####*, with the same services such as console and network as are normally provided at launch to applications referenced by a *Boot####* variable. *SysPrep####* application must exit and may not call **ExitBootServices()**. Processing of any Error Code returned at exit is according to system policy and does not necessarily change processing of following boot options. Any driver portion of

the feature supported by *SysPrep####* boot option that is required to remain resident should be loaded by use of *Driver####* variable.

The Attributes option **LOAD_OPTION_FORCE_RECONNECT** is ignored for *SysPrep####* variables, and in the event that an application so launched performs some action that adds to the available hardware or drivers, the system preparation application shall itself utilize appropriate calls to **ConnectController()** or **DisconnectController()** to revise connections between drivers and hardware.

After all *SysPrep####* variables have been launched and exited, the platform shall notify **EFI_EVENT_GROUP_READY_TO_BOOT** event group and begin to evaluate *Boot####* variables with Attributes set to **LOAD_OPTION_CATEGORY_BOOT** according to the order defined by *BootOrder*. The *FilePathList* of variables marked **LOAD_OPTION_CATEGORY_BOOT** shall not be evaluated prior to the completion of **EFI_EVENT_GROUP_READY_TO_BOOT** event group processing.

3.2 Boot Manager Policy Protocol

EFI_BOOT_MANAGER_POLICY_PROTOCOL

Summary

This protocol is used by EFI Applications to request the UEFI Boot Manager to connect devices using platform policy.

GUID

```
#define EFI_BOOT_MANAGER_POLICY_PROTOCOL_GUID \
{ 0xFEDF8E0C, 0xE147, 0x11E3, \
  { 0x99, 0x03, 0xB8, 0xE8, 0x56, 0x2C, 0xBA, 0xFA } }
```

Protocol Interface Structure

```
typedef struct _EFI_BOOT_MANAGER_POLICY_PROTOCOL
EFI_BOOT_MANAGER_POLICY_PROTOCOL;
struct _EFI_BOOT_MANAGER_POLICY_PROTOCOL {
    UINT64 Revision;
    EFI_BOOT_MANAGER_POLICY_CONNECT_DEVICE_PATH ConnectDevicePath;
    EFI_BOOT_MANAGER_POLICY_CONNECT_DEVICE_CLASS ConnectDeviceClass;
};
```

ConnectDevicePath Connect a Device Path following the platforms EFI Boot Manager policy.

ConnectDeviceClass Connect a class of devices, named by **EFI_GUID**, following the platforms UEFI Boot Manager policy.

Description

The **EFI_BOOT_MANAGER_PROTOCOL** is produced by the platform firmware to expose Boot Manager policy and platform specific [EFI_BOOT_SERVICES.ConnectController\(\)](#) behavior.

Related Definitions

```
#define EFI_BOOT_MANAGER_POLICY_PROTOCOL_REVISION 0x00010000
```

EFI_BOOT_MANAGER_PROTOCOL.ConnectDevicePath()

Summary

Connect a device path following the platform’s EFI Boot Manager policy.

```

Prototype
typedef
EFI_STATUS
(EFIAPI *EFI_BOOT_MANAGER_POLICY_CONNECT_DEVICE_PATH) (
    IN EFI_BOOT_MANAGER_POLICY_PROTOCOL *This,
    IN EFI_DEVICE_PATH                 *DevicePath,
    IN BOOLEAN                          Recursive
);
    
```

Parameters

- | | |
|------------|--|
| This | A pointer to the EFI_BOOT_MANAGER_POLICY_PROTOCOL instance. Type EFI_BOOT_MANAGER_POLICY_PROTOCOL defined above. |
| DevicePath | Points to the start of the EFI device path to connect. If <i>DevicePath</i> is NULL then all the controllers in the system will be connected using the platform’s EFI Boot Manager policy. |
| Recursive | If TRUE , then ConnectController() is called recursively until the entire tree of controllers below the controller specified by <i>DevicePath</i> have been created. If FALSE , then the tree of controllers is only expanded one level. If <i>DevicePath</i> is NULL then <i>Recursive</i> is ignored. |

Description

The **ConnectDevicePath()** function allows the caller to connect a *DevicePath* using the same policy as the EFI Boot Manager.

If *Recursive* is **TRUE**, then **ConnectController()** is called recursively until the entire tree of controllers below the controller specified by *DevicePath* have been created. If *Recursive* is **FALSE**, then the tree of controllers is only expanded one level. If *DevicePath* is NULL then *Recursive* is ignored.

Status Codes Returned

EFI_SUCCESS	The <i>DevicePath</i> was connected
EFI_NOT_FOUND	The <i>DevicePath</i> was not found
EFI_NOT_FOUND	No driver was connected to <i>DevicePath</i> .
EFI_SECURITY_VIOLATION	The user has no permission to start UEFI device drivers on the <i>DevicePath</i> .
EFI_UNSUPPORTED	The current TPL is not TPL APPLICATION .

EFI_BOOT_MANAGER_PROTOCOL.ConnectDeviceClass()

Summary

Connect a class of devices using the platform Boot Manager policy.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_BOOT_MANAGER_POLICY_CONNECT_DEVICE_CLASS) (
    IN EFI_BOOT_MANAGER_POLICY_PROTOCOL *This,
    IN EFI_GUID                          *Class
);
```

Parameters

<i>This</i>	A pointer to the EFI_BOOT_MANAGER_POLICY_PROTOCOL instance. Type EFI_BOOT_MANAGER_POLICY_PROTOCOL is defined above.
<i>Class</i>	A pointer to an EFI_GUID that represents a class of devices that will be connected using the Boot Manager's platform policy.

Description

The **ConnectDeviceClass()** function allows the caller to request that the Boot Manager connect a class of devices.

If *Class* is **EFI_BOOT_MANAGER_POLICY_CONSOLE_GUID** then the Boot Manager will use platform policy to connect consoles. Some platforms may restrict the number of consoles connected as they attempt to fast boot, and calling **ConnectDeviceClass()** with a *Class* value of **EFI_BOOT_MANAGER_POLICY_CONSOLE_GUID** must connect the set of consoles that follow the Boot Manager platform policy, and the **EFI_SIMPLE_TEXT_INPUT_PROTOCOL**, **EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL**, and the **EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL** are produced on the connected handles. The Boot Manager may restrict which consoles get connect due to platform policy, for example a security policy may require that a given console is not connected.

If *Class* is **EFI_BOOT_MANAGER_POLICY_NETWORK_GUID** then the Boot Manager will connect the protocols the platform supports for UEFI general purpose network applications on one or more handles. The protocols associated with UEFI general purpose network applications are defined in [Section 2.6.2](#), list item number 7. If more than one network controller is available a platform will connect, one, many, or all of the networks based on platform policy. Connecting UEFI networking protocols, like **EFI_DHCP4_PROTOCOL**, does not establish connections on the network. The UEFI general purpose network application that called **ConnectDeviceClass()** may need to use the published protocols to establish the network connection. The Boot Manager can optionally have a policy to establish a network connection.

If *Class* is **EFI_BOOT_MANAGER_POLICY_CONNECT_ALL_GUID** then the Boot Manager will connect all UEFI drivers using the UEFI Boot Service [EFI_BOOT_SERVICES.ConnectController\(\)](#). If the Boot Manager has policy associated with connect all UEFI drivers this policy will be used.

A platform can also define platform specific *Class* values as a properly generated **EFI_GUID** would never conflict with this specification.

#define EFI_BOOT_MANAGER_POLICY_CONNECT_ALL_GUID \
    { 0x113B2126, 0xFC8A, 0x11E3, \
      { 0xBD, 0x6C, 0xB8, 0xE8, 0x56, 0x2C, 0xBA, 0xFA } }
```

Status Codes Returned

EFI_SUCCESS	At least one devices of the <i>Class</i> was connected.
EFI_DEVICE_ERROR	Devices were not connected due to an error.
EFI_NOT_FOUND	The <i>Class</i> is not supported by the platform.
EFI_UNSUPPORTED	The current TPL is not TPL APPLICATION .

3.3 Globally Defined Variables

This section defines a set of variables that have architecturally defined meanings. In addition to the defined data content, each such variable has an architecturally defined attribute that indicates when the data variable may be accessed. The variables with an attribute of NV are nonvolatile. This means that their values are persistent across resets and power cycles. The value of any environment variable that does not have this attribute will be lost when power is removed from the system and the state of firmware reserved memory is not otherwise preserved. The variables with an attribute of BS are only available before [EFI_BOOT_SERVICES.ExitBootServices\(\)](#) is called. This means that these environment variables can only be retrieved or modified in the preboot environment. They are not visible to an operating system. Environment variables with an attribute of RT are available before and after [ExitBootServices\(\)](#) is called. Environment variables of this type can be retrieved and modified in the preboot environment, and from an operating system. The variables with an attribute of AT are variables with a time-based authenticated write access defined in [Section 7.2.1](#). All architecturally defined variables use the **EFI_GLOBAL_VARIABLE** *VendorGuid*:

```
#define EFI_GLOBAL_VARIABLE \
    { 0x8BE4DF61, 0x93CA, 0x11d2, \
      { 0xAA, 0x0D, 0x00, 0xE0, 0x98, 0x03, 0x2B, 0x8C } }
```

To prevent name collisions with possible future globally defined variables, other internal firmware data variables that are not defined here must be saved with a unique *VendorGuid* other than **EFI_GLOBAL_VARIABLE** or any other GUID defined by the UEFI Specification.

Implementations must only permit the creation of variables with a UEFI Specification-defined *VendorGuid* when these variables are documented in the UEFI Specification.

Table 11. Global Variables

Variable Name	Attribute	Description
AuditMode	BS, RT	Whether the system is operating in Audit Mode (1) or not (0). All other values are reserved. Should be treated as read-only except when DeployedMode is 0. Always becomes read-only after ExitBootServices() is called.
Boot####	NV, BS, RT	A boot load option. #### is a printed hex value. No 0x or h is included in the hex value.
BootCurrent	BS, RT	The boot option that was selected for the current boot.
BootNext	NV, BS, RT	The boot option for the next boot only.
BootOrder	NV, BS, RT	The ordered boot option load list.
BootOptionSupport	BS,RT,	The types of boot options supported by the boot manager. Should be treated as read-only.
ConIn	NV, BS, RT	The device path of the default input console.
ConInDev	BS, RT	The device path of all possible console input devices.
ConOut	NV, BS, RT	The device path of the default output console.
ConOutDev	BS, RT	The device path of all possible console output devices.
dbDefault	BS, RT	The OEM's default secure boot signature store. Should be treated as read-only.
dbrDefault	BS, RT	The OEM's default OS Recovery signature store. Should be treated as read-only.
dbtDefault	BS, RT	The OEM's default secure boot timestamp signature store. Should be treated as read-only.
dbxDefault	BS, RT	The OEM's default secure boot blacklist signature store. Should be treated as read-only.
DeployedMode	BS, RT	Whether the system is operating in Deployed Mode (1) or not (0). All other values are reserved. Should be treated as read-only when its value is 1. Always becomes read-only after ExitBootServices() is called.
Driver####	NV, BS, RT	A driver load option. #### is a printed hex value.
DriverOrder	NV, BS, RT	The ordered driver load option list.
ErrOut	NV, BS, RT	The device path of the default error output device.
ErrOutDev	BS, RT	The device path of all possible error output devices.
HwErrRecSupport	NV, BS, RT	Identifies the level of hardware error record persistence support implemented by the platform. This variable is only modified by firmware and is read-only to the OS.
KEK	NV, BS, RT,AT	The Key Exchange Key Signature Database.
KEKDefault	BS, RT	The OEM's default Key Exchange Key Signature Database. Should be treated as read-only.
Key####	NV, BS, RT	Describes hot key relationship with a Boot#### load option.

Variable Name	Attribute	Description
Lang	NV, BS, RT	The language code that the system is configured for. This value is deprecated.
LangCodes	BS, RT	The language codes that the firmware supports. This value is deprecated.
OsIndications	NV, BS, RT	Allows the OS to request the firmware to enable certain features and to take certain actions.
OsIndicationsSupported	BS, RT	Allows the firmware to indicate supported features and actions to the OS.
OsRecoveryOrder	BS,RT,NV,AT	OS-specified recovery options.
PK	NV, BS, RT,AT	The public Platform Key.
PKDefault	BS, RT	The OEM's default public Platform Key. Should be treated as read-only.
PlatformLangCodes	BS, RT	The language codes that the firmware supports.
PlatformLang	NV, BS, RT	The language code that the system is configured for.
PlatformRecovery####	BS, RT	Platform-specified recovery options. These variables are only modified by firmware and are read-only to the OS.
SignatureSupport	BS, RT	Array of GUIDs representing the type of signatures supported by the platform firmware. Should be treated as read-only.
SecureBoot	BS, RT	Whether the platform firmware is operating in Secure boot mode (1) or not (0). All other values are reserved. Should be treated as read-only.
SetupMode	BS, RT	Whether the system should require authentication on SetVariable() requests to Secure Boot policy variables (0) or not (1). Should be treated as read-only. The system is in "Setup Mode" when SetupMode==1, AuditMode==0, and DeployedMode==0.
SysPrep####	NV, BS, RT	A System Prep application load option containing a EFI_LOAD_OPTION descriptor. #### is a printed hex value.
SysPrepOrder	NV, BS, RT	The ordered System Prep Application load option list.
Timeout	NV, BS, RT	The firmware's boot managers timeout, in seconds, before initiating the default boot selection.
VendorKeys	BS, RT	Whether the system is configured to use only vendor-provided keys or not. Should be treated as read-only.

The *PlatformLangCodes* variable contains a null-terminated ASCII string representing the language codes that the firmware can support. At initialization time the firmware computes the supported languages and creates this data variable. Since the firmware creates this value on each initialization, its contents are not stored in nonvolatile memory. This value is considered read-only. *PlatformLangCodes* is specified in Native RFC 4646 format. See [Appendix M](#). *LangCodes* is deprecated and may be provided for backwards compatibility.

The *PlatformLang* variable contains a null-terminated ASCII string language code that the machine has been configured for. This value may be changed to any value supported by

PlatformLangCodes. If this change is made in the preboot environment, then the change will take effect immediately. If this change is made at OS runtime, then the change does not take effect until the next boot. If the language code is set to an unsupported value, the firmware will choose a supported default at initialization and set *PlatformLang* to a supported value. *PlatformLang* is specified in Native RFC 4646 array format. See [Appendix M](#). *Lang* is deprecated and may be provided for backwards compatibility.

Lang has been deprecated. If the platform supports this variable, it must map any changes in the *Lang* variable into *PlatformLang* in the appropriate format.

Langcodes has been deprecated. If the platform supports this variable, it must map any changes in the *Langcodes* variable into *PlatformLang* in the appropriate format.

The *Timeout* variable contains a binary **UINT16** that supplies the number of seconds that the firmware will wait before initiating the original default boot selection. A value of 0 indicates that the default boot selection is to be initiated immediately on boot. If the value is not present, or contains the value of 0xFFFF then firmware will wait for user input before booting. This means the default boot selection is not automatically started by the firmware.

The *ConIn*, *ConOut*, and *ErrOut* variables each contain an **EFI_DEVICE_PATH_PROTOCOL** descriptor that defines the default device to use on boot. Changes to these values made in the preboot environment take effect immediately. Changes to these values at OS runtime do not take effect until the next boot. If the firmware cannot resolve the device path, it is allowed to automatically replace the values, as needed, to provide a console for the system. If the device path starts with a USB Class device path (see [Table 64](#)), then any input or output device that matches the device path must be used as a console if it is supported by the firmware.

The *ConInDev*, *ConOutDev*, and *ErrOutDev* variables each contain an **EFI_DEVICE_PATH_PROTOCOL** descriptor that defines all the possible default devices to use on boot. These variables are volatile, and are set dynamically on every boot. *ConIn*, *ConOut*, and *ErrOut* are always proper subsets of *ConInDev*, *ConOutDev*, and *ErrOutDev*.

Each *Boot####* variable contains an **EFI_LOAD_OPTION**. Each *Boot####* variable is the name “Boot” appended with a unique four digit hexadecimal number. For example, Boot0001, Boot0002, Boot0A02, etc.

The *OsRecoveryOrder* variable contains an array of **EFI_GUID** structures. Each **EFI_GUID** structure specifies a namespace for variables containing OS-defined recovery entries (see [Section 3.4.1](#)). Write access to this variable is controlled by the security key database dbr (see [Section 7.2.1](#)).

PlatformRecovery#### variables share the same structure as *Boot####* variables. These variables are processed when the system is performing recovery of boot options

The *BootOrder* variable contains an array of **UINT16**'s that make up an ordered list of the *Boot####* options. The first element in the array is the value for the first logical boot option, the second element is the value for the second logical boot option, etc. The *BootOrder* order list is used by the firmware's boot manager as the default boot order.

The *BootNext* variable is a single **UINT16** that defines the *Boot####* option that is to be tried first on the next boot. After the *BootNext* boot option is tried the normal *BootOrder* list is used. To prevent loops, the boot manager deletes this variable before transferring control to the preselected boot option.

The *BootCurrent* variable is a single **UINT16** that defines the *Boot####* option that was selected on the current boot.

The *BootOptionSupport* variable is a **UINT32** that defines the types of boot options supported by the boot manager.

Each *Driver####* variable contains an **EFI_LOAD_OPTION**. Each load option variable is appended with a unique number, for example *Driver0001*, *Driver0002*, etc.

The *DriverOrder* variable contains an array of **UINT16**'s that make up an ordered list of the *Driver####* variable. The first element in the array is the value for the first logical driver load option, the second element is the value for the second logical driver load option, etc. The *DriverOrder* list is used by the firmware's boot manager as the default load order for UEFI drivers that it should explicitly load.

The *Key####* variable associates a key press with a single boot option. Each *Key####* variable is the name "Key" appended with a unique four digit hexadecimal number. For example, *Key0001*, *Key0002*, *Key00A0*, etc.

The *HwErrRecSupport* variable contains a binary **UINT16** that supplies the level of support for Hardware Error Record Persistence (see [Section 7.2.3](#)) that is implemented by the platform. If the value is not present, then the platform implements no support for Hardware Error Record Persistence. A value of zero indicates that the platform implements no support for Hardware Error Record Persistence. A value of 1 indicates that the platform implements Hardware Error Record Persistence as defined in [Section 7.2.3](#). Firmware initializes this variable. All other values are reserved for future use.

The *SetupMode* variable is an 8-bit unsigned integer that defines whether the system is should require authentication (0) or not (1) on **SetVariable()** requests to Secure Boot Policy Variables. Secure Boot Policy Variables include:

- The global variables *PK*, *KEK*, and *OsRecoveryOrder*
- All variables named *OsRecovery####* under all VendorGuids
- All variables with the VendorGuid **EFI_IMAGE_SECURITY_DATABASE_GUID**.

Secure Boot Policy Variables must be created using the **EFI_VARIABLE_AUTHENTICATION_2** structure.

The *AuditMode* variable is an 8-bit unsigned integer that defines whether the system is currently operating in Audit Mode.

The *DeployedMode* variable is an 8-bit unsigned integer that defines whether the system is currently operating in Deployed Mode.

The *KEK* variable contains the current Key Exchange Key database.

The *PK* variable contains the current Platform Key.

The *VendorKeys* variable is an 8-bit unsigned integer that defines whether the Security Boot Policy Variables have been modified by anyone other than the platform vendor or a holder of the vendor-provided keys. A value of 0 indicates that someone other than the platform vendor or a holder of the vendor-provided keys has modified the Secure Boot Policy Variables Otherwise, the value will be 1.

The *KEKDefault* variable, if present, contains the platform-defined Key Exchange Key database. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key

setup. The contents of this variable do not include an **EFI_VARIABLE_AUTHENTICATION** or **EFI_VARIABLE_AUTHENTICATION2** structure.

The *PKDefault* variable, if present, contains the platform-defined Platform Key. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an **EFI_VARIABLE_AUTHENTICATION2** structure.

The *dbDefault* variable, if present, contains the platform-defined secure boot signature database. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an **EFI_VARIABLE_AUTHENTICATION2** structure.

The *dbrDefault* variable, if present, contains the platform-defined secure boot authorized recovery signature database. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an **EFI_VARIABLE_AUTHENTICATION2** structure.

The *dbtDefault* variable, if present, contains the platform-defined secure boot timestamp signature database. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an **EFI_VARIABLE_AUTHENTICATION2** structure.

The *dbxDefault* variable, if present, contains the platform-defined secure boot blacklist signature database. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an **EFI_VARIABLE_AUTHENTICATION2** structure.

The *SignatureSupport* variable returns an array of GUIDs, with each GUID representing a type of signature which the platform firmware supports for images and other data. The different signature types are described in "Signature Database".

The *SecureBoot* variable is an 8-bit unsigned integer that defines if the platform firmware is operating in secure boot mode. A value of 1 indicates that platform firmware performs driver and boot application signature verification as specified in [Section 30.5](#) during the current boot. A value of 0 indicates that driver and boot application signature verification is not active during the current boot. The platform firmware is operating in secure boot mode if the value of the *SetupMode* variable is 0 and the *SecureBoot* variable is set to 1. A platform cannot operate in secure boot mode if the *SetupMode* variable is set to 1. The *SecureBoot* variable should be treated as read-only.

The *OsIndicationsSupported* variable indicates which of the OS indication features and actions that the firmware supports. This variable is recreated by firmware every boot, and cannot be modified by the OS (see **SetVariable ()** Attributes usage rules once **ExitBootServices ()** is performed).

The *OsIndications* variable is used to indicate which features the OS wants firmware to enable or which actions the OS wants the firmware to take. The OS will supply this data with a **SetVariable ()** call. See [Section 7.5.4](#) for the variable definition.

3.4 Boot Option Recovery

Boot option recovery consists of two independent parts, *operating system-defined* recovery and *platform-defined* recovery. OS-defined recovery is an attempt to allow installed operating systems to

recover any needed boot options, or to launch full operating system recovery. Platform-defined recovery includes any remedial actions performed by the platform as a last resort when no operating system is found, such as the *Default Boot Behavior* (see [Section 3.4.3](#)). This could include behaviors such as warranty service reconfiguration or diagnostic options.

In the event that boot option recovery must be performed, the boot manager must first attempt OS-defined recovery, re-attempt normal booting via *Boot####* and *BootOrder* variables, and finally attempt platform-defined recovery if no options have succeeded.

3.4.1 OS-Defined Boot Option Recovery

If the **EFI_OS_INDICATIONS_START_OS_RECOVERY** bit is set in *OsIndications*, or if processing of *BootOrder* does not result in success, the platform must process OS-defined recovery options. In the case where OS-defined recovery is entered due to *OsIndications*, *SysPrepOrder* and *SysPrep####* variables should not be processed. Note that in order to avoid ambiguity in intent, this bit is ignored in *OsIndications* if **EFI_OS_INDICATIONS_START_PLATFORM_RECOVERY** is set.

OS-defined recovery uses the *OsRecoveryOrder* variable, as well as variables created with vendor specific *VendorGuid* values and a name following the pattern *OsRecovery####*. Each of these variables must be an authenticated variable with the **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute set.

To process these variables, the boot manager iterates over the array of **EFI_GUID** structures in the *OsRecoveryOrder* variable, and each GUID specified is treated as a *VendorGuid* associated with a series of variable names. For each GUID, the firmware attempts to load and execute, in hexadecimal sort order, every variable with that GUID and a name following the pattern *OsRecovery####*. These variables have the same format as *Boot####* variables, and the boot manager must verify that each variable it attempts to load was created with a public key that is associated with a certificate chaining to one listed in the authorized recovery signature database *dbx* or the Key Exchange Key database *KEK*, or by the current Platform Key *PK*.

If the boot manager finishes processing *OsRecovery####* options without [EFI_BOOT_SERVICES.ExitBootServices\(\)](#) or [ResetSystem\(\)](#) having been called, it must attempt to process *BootOrder* a second time. If booting does not succeed during that process, OS-defined recovery has failed, and the boot manager must attempt platform-based recovery.

If, while processing *OsRecovery####* variables, the boot manager encounters an entry which cannot be loaded or executed due to a security policy violation, it must ignore that variable.

3.4.2 Platform-Defined Boot Option Recovery

If the **EFI_OS_INDICATIONS_START_PLATFORM_RECOVERY** bit is set in *OsIndications*, or if OS-defined recovery has failed, the system firmware must commence with platform-specific recovery by iterating its *PlatformRecovery####* variables in the same manner as *OsRecovery####*, but must stop processing if any entry is successful. In the case where platform-specific recovery is entered due to *OsIndications*, *SysPrepOrder* and *SysPrep####* variables should not be processed.

3.4.3 Boot Option Variables Default Boot Behavior

The default state of globally-defined variables is firmware vendor specific. However the boot options require a standard default behavior in the exceptional case that valid boot options are not present on a platform. The default behavior must be invoked any time the *BootOrder* variable does not exist or only points to nonexistent boot options, or if no entry in *BootOrder* can successfully be executed.

If system firmware supports boot option recovery as described in [Section 3.4](#), system firmware must include a *PlatformRecovery####* variable specifying a short-form File Path Media Device Path (see [Section 3.1.2](#)) containing the platform default file path for removable media (see [Table 12](#)). It is recommended for maximal compatibility with prior versions of this specification that this entry be the first such variable, though it may be at any position within the list.

It is expected that this default boot will load an operating system or a maintenance utility. If this is an operating system setup program it is then responsible for setting the requisite environment variables for subsequent boots. The platform firmware may also decide to recover or set to a known set of boot options.

3.5 Boot Mechanisms

EFI can boot from a device using the **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL** or the **EFI_LOAD_FILE_PROTOCOL**. A device that supports the **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL** must materialize a file system protocol for that device to be bootable. If a device does not wish to support a complete file system it may produce an **EFI_LOAD_FILE_PROTOCOL** which allows it to materialize an image directly. The Boot Manager will attempt to boot using the **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL** first. If that fails, then the **EFI_LOAD_FILE_PROTOCOL** will be used.

3.5.1 Boot via the Simple File Protocol

When booting via the **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL**, the *FilePath* will start with a device path that points to the device that implements the **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL** or the **EFI_BLOCK_IO_PROTOCOL**. The next part of the *FilePath* may point to the file name, including subdirectories, which contain the bootable image. If the file name is a null device path, the file name must be generated from the rules defined below.

If the *FilePathList[0]* device does not support the **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL**, but supports the **EFI_BLOCK_IO_PROTOCOL** protocol, then the EFI Boot Service [**EFI_BOOT_SERVICES.ConnectController\(\)**](#) must be called for *FilePathList[0]* with *DriverImageHandle* and *RemainingDevicePath* set to **NULL** and the *Recursive* flag is set to **TRUE**. The firmware will then attempt to boot from any child handles produced using the algorithms outlined below.

The format of the file system specified is contained in [Section 12.3](#). While the firmware must produce an **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL** that understands the UEFI file system, any file system can be abstracted with the **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL** interface.

3.5.1.1 Removable Media Boot Behavior

To generate a file name when none is present in the *FilePath*, the firmware must append a default file name in the form `\EFI\BOOT\BOOT{machine type short-name}.EFI` where machine type short-name defines a PE32+ image format architecture. Each file only contains one UEFI image type, and a system may support booting from one or more images types. [Table 12](#) lists the UEFI image types.

Table 12. UEFI Image Types

	File Name Convention	PE Executable Machine Type *
32-bit	BOOTIA32.EFI	0x14c
x64	BOOTx64.EFI	0x8664
Itanium architecture	BOOTIA64.EFI	0x200
AArch32 architecture	BOOTARM.EFI	0x01c2
AArch64 architecture	BOOTAA64.EFI	0xAA64
Note: * The PE Executable machine type is contained in the machine field of the COFF file header as defined in the Microsoft Portable Executable and Common Object File Format Specification, Revision 6.0		

Media may support multiple architectures by simply having a `\EFI\BOOT\BOOT{machine type short-name}.EFI` file of each possible machine type.

3.5.2 Boot via the Load File Protocol

When booting via the [EFI LOAD FILE PROTOCOL](#), the *FilePath* is a device path that points to a device that “speaks” the [EFI_LOAD_FILE_PROTOCOL](#). The image is loaded directly from the device that supports the [EFI_LOAD_FILE_PROTOCOL](#). The remainder of the *FilePath* will contain information that is specific to the device. Firmware passes this device-specific data to the loaded image, but does not use it to load the image. If the remainder of the *FilePath* is a null device path it is the loaded image's responsibility to implement a policy to find the correct boot device.

The [EFI_LOAD_FILE_PROTOCOL](#) is used for devices that do not directly support file systems. Network devices commonly boot in this model where the image is materialized without the need of a file system.

3.5.2.1 Network Booting

Network booting is described by the *Preboot eXecution Environment (PXE) BIOS Support Specification* that is part of the *Wired for Management Baseline specification*. PXE specifies UDP, DHCP, and TFTP network protocols that a booting platform can use to interact with an intelligent system load server. UEFI defines special interfaces that are used to implement PXE. These interfaces are contained in the [EFI_PXE_BASE_CODE_PROTOCOL](#) (see [Section 23.3](#)).

3.5.2.2 Future Boot Media

Since UEFI defines an abstraction between the platform and the OS and its loader it should be possible to add new types of boot media as technology evolves. The OS loader will not necessarily have to change to support new types of boot. The implementation of the UEFI platform services may change, but the interface will remain constant. The OS will require a driver to support the

new type of boot media so that it can make the transition from UEFI boot services to OS control of the boot media.

EFI System Table

This section describes the entry point to a UEFI image and the parameters that are passed to that entry point. There are three types of UEFI images that can be loaded and executed by firmware conforming to this specification. These are UEFI applications (see [Section 2.1.2](#)), UEFI boot service drivers (see [Section 2.1.4](#)), and UEFI runtime drivers (see [Section 2.1.4](#)). UEFI applications include UEFI OS loaders (see [Section 2.1.3](#)). There are no differences in the entry point for these three image types.

4.1 UEFI Image Entry Point

The most significant parameter that is passed to an image is a pointer to the System Table. This pointer is [EFI_IMAGE_ENTRY_POINT](#) (see definition immediately below), the main entry point for a UEFI Image. The System Table contains pointers to the active console devices, a pointer to the Boot Services Table, a pointer to the Runtime Services Table, and a pointer to the list of system configuration tables such as ACPI, SMBIOS, and the SAL System Table. This section describes the System Table in detail.

EFI_IMAGE_ENTRY_POINT

Summary

This is the main entry point for a UEFI Image. This entry point is the same for UEFI applications and UEFI drivers.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_IMAGE_ENTRY_POINT) (
    IN EFI_HANDLE          ImageHandle,
    IN EFI_SYSTEM_TABLE   *SystemTable
);
```

Parameters

<i>ImageHandle</i>	The firmware allocated handle for the UEFI image.
<i>SystemTable</i>	A pointer to the EFI System Table.

Description

This function is the entry point to an EFI image. An EFI image is loaded and relocated in system memory by the EFI Boot Service [EFI_BOOT_SERVICES.LoadImage\(\)](#). An EFI image is invoked through the EFI Boot Service [EFI_BOOT_SERVICES.StartImage\(\)](#).

The first argument is the image’s image handle. The second argument is a pointer to the image’s system table. The system table contains the standard output and input handles, plus pointers to the [EFI_BOOT_SERVICES](#) and [EFI_RUNTIME_SERVICES](#) tables. The service tables contain the entry points in the firmware for accessing the core EFI system functionality. The handles in the system table are used to obtain basic access to the console. In addition, the System Table contains pointers to other standard tables that a loaded image may use if the associated pointers are initialized to nonzero values. Examples of such tables are ACPI, SMBIOS, SAL System Table, etc.

The *ImageHandle* is a firmware-allocated handle that is used to identify the image on various functions. The handle also supports one or more protocols that the image can use. All images support the [EFI_LOADED_IMAGE_PROTOCOL](#) and the [EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL](#) that returns the source location of the image, the memory location of the image, the load options for the image, etc. The exact [EFI_LOADED_IMAGE_PROTOCOL](#) and [EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL](#) structures are defined in [Section 8](#).

If the UEFI image is a UEFI application that is not a UEFI OS loader, then the application executes and either returns or calls the EFI Boot Services [EFI_BOOT_SERVICES.Exit\(\)](#). A UEFI application is always unloaded from memory when it exits, and its return status is returned to the component that started the UEFI application.

If the UEFI image is a UEFI OS Loader, then the UEFI OS Loader executes and either returns, calls the EFI Boot Service [Exit\(\)](#), or calls the EFI Boot Service [EFI_BOOT_SERVICES.ExitBootServices\(\)](#). If the EFI OS Loader returns or calls [Exit\(\)](#), then the load of the OS has failed, and the EFI OS Loader is unloaded from memory and control is returned to the component that attempted to boot the UEFI OS Loader. If [ExitBootServices\(\)](#) is called, then the UEFI OS Loader has taken control of the platform, and EFI will not regain control of the system until the platform is reset. One method of resetting the platform is through the EFI Runtime Service [ResetSystem\(\)](#).

If the UEFI image is a UEFI Driver, then the UEFI driver executes and either returns or calls the Boot Service [Exit\(\)](#). If the UEFI driver returns an error, then the driver is unloaded from memory. If the UEFI driver returns [EFI_SUCCESS](#), then it stays resident in memory. If the UEFI driver does not follow the UEFI Driver Model, then it performs any required initialization and installs its protocol services before returning. If the driver does follow the UEFI Driver Model, then the entry point is not allowed to touch any device hardware. Instead, the entry point is required to create and install the [EFI_DRIVER_BINDING_PROTOCOL](#) (see [Section 10.1](#)) on the *ImageHandle* of the UEFI driver. If this process is completed, then [EFI_SUCCESS](#) is returned. If the resources are not available to complete the UEFI driver initialization, then [EFI_OUT_OF_RESOURCES](#) is returned.

Status Codes Returned

EFI_SUCCESS	The driver was initialized.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

4.2 EFI Table Header

The data type [EFI_TABLE_HEADER](#) is the data structure that precedes all of the standard EFI table types. It includes a signature that is unique for each table type, a revision of the table that may be

updated as extensions are added to the EFI table types, and a 32-bit CRC so a consumer of an EFI table type can validate the contents of the EFI table.

EFI_TABLE_HEADER

Summary

Data structure that precedes all of the standard EFI table types.

Related Definitions

```
typedef struct {
    UINT64    Signature;
    UINT32    Revision;
    UINT32    HeaderSize;
    UINT32    CRC32;
    UINT32    Reserved;
} EFI_TABLE_HEADER;
```

Parameters

Signature

A 64-bit signature that identifies the type of table that follows. Unique signatures have been generated for the EFI System Table, the EFI Boot Services Table, and the EFI Runtime Services Table.

Revision

The revision of the EFI Specification to which this table conforms. The upper 16 bits of this field contain the major revision value, and the lower 16 bits contain the minor revision value. The minor revision values are binary coded decimals and are limited to the range of 00..99.

When printed or displayed UEFI spec revision is referred as (Major revision).(Minor revision upper decimal).(Minor revision lower decimal) or (Major revision).(Minor revision upper decimal) in case Minor revision lower decimal is set to 0. For example:

A specification with the revision value $((2 \ll 16) | (30))$ would be referred as 2.3;

A specification with the revision value $((2 \ll 16) | (31))$ would be referred as 2.3.1

HeaderSize

The size, in bytes, of the entire table including the **EFI_TABLE_HEADER**.

CRC32

The 32-bit CRC for the entire table. This value is computed by setting this field to 0, and computing the 32-bit CRC for *HeaderSize* bytes.

Reserved

Reserved field that must be set to 0.

Note: The capabilities found in the EFI system table, runtime table and boot services table may change over time. The first field in each of these tables is an **EFI_TABLE_HEADER**. This header's

Revision field is incremented when new capabilities and functions are added to the functions in the table. When checking for capabilities, code should verify that Revision is greater than or equal to the revision level of the table at the point when the capabilities were added to the UEFI specification.

Note: Unless otherwise specified, UEFI uses a standard CCITT32 CRC algorithm with a seed polynomial value of 0x04c11db7 for its CRC calculations.

Note: The size of the system table, runtime services table, and boot services table may increase over time. It is very important to always use the *HeaderSize* field of the **EFI_TABLE_HEADER** to determine the size of these tables.

4.3 EFI System Table

UEFI uses the EFI System Table, which contains pointers to the runtime and boot services tables. The definition for this table is shown in the following code fragments. Except for the table header, all elements in the service tables are pointers to functions as defined in [Section 6](#) and [Section 7](#). Prior to a call to [EFI_BOOT_SERVICES.ExitBootServices\(\)](#), all of the fields of the EFI System Table are valid. After an operating system has taken control of the platform with a call to **ExitBootServices()**, only the *Hdr*, *FirmwareVendor*, *FirmwareRevision*, *RuntimeServices*, *NumberOfTableEntries*, and *ConfigurationTable* fields are valid.

EFI_SYSTEM_TABLE

Summary

Contains pointers to the runtime and boot services tables.

} EFI_SYSTEM_TABLE;

```

Parameters

<i>Hdr</i>	The table header for the EFI System Table. This header contains the EFI_SYSTEM_TABLE_SIGNATURE and EFI_SYSTEM_TABLE_REVISION values along with the size of the EFI_SYSTEM_TABLE structure and a 32-bit CRC to verify that the contents of the EFI System Table are valid.
<i>FirmwareVendor</i>	A pointer to a null terminated string that identifies the vendor that produces the system firmware for the platform.
<i>FirmwareRevision</i>	A firmware vendor specific value that identifies the revision of the system firmware for the platform.
<i>ConsoleInHandle</i>	The handle for the active console input device. This handle must support EFI_SIMPLE_TEXT_INPUT_PROTOCOL and EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL .
<i>ConIn</i>	A pointer to the EFI_SIMPLE_TEXT_INPUT_PROTOCOL interface that is associated with <i>ConsoleInHandle</i> .
<i>ConsoleOutHandle</i>	The handle for the active console output device. This handle must support the EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL .
<i>ConOut</i>	A pointer to the EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL interface that is associated with <i>ConsoleOutHandle</i> .
<i>StandardErrorHandle</i>	The handle for the active standard error console device. This handle must support the EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL .
<i>StdErr</i>	A pointer to the EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL interface that is associated with <i>StandardErrorHandle</i> .
<i>RuntimeServices</i>	A pointer to the EFI Runtime Services Table. See Section 4.5 .
<i>BootServices</i>	A pointer to the EFI Boot Services Table. See Section 4.4 .
<i>NumberOfTableEntries</i>	The number of system configuration tables in the buffer <i>ConfigurationTable</i> .
<i>ConfigurationTable</i>	A pointer to the system configuration tables. The number of entries in the table is <i>NumberOfTableEntries</i> .

4.4 EFI Boot Services Table

UEFI uses the EFI Boot Services Table, which contains a table header and pointers to all of the boot services. The definition for this table is shown in the following code fragments. Except for the table header, all elements in the EFI Boot Services Tables are prototypes of function pointers to functions as defined in [Section 6](#). The function pointers in this table are not valid after the operating system has taken control of the platform with a call to [EFI_BOOT_SERVICES.ExitBootServices\(\)](#).

EFI_BOOT_SERVICES

Summary

Contains a table header and pointers to all of the boot services.

} EFI_BOOT_SERVICES;

```

Parameters

Hdr

The table header for the EFI Boot Services Table. This header contains the **EFI_BOOT_SERVICES_SIGNATURE** and **EFI_BOOT_SERVICES_REVISION** values along with the size

	of the EFI_BOOT_SERVICES structure and a 32-bit CRC to verify that the contents of the EFI Boot Services Table are valid.
<i>RaiseTPL</i>	Raises the task priority level.
<i>RestoreTPL</i>	Restores/lowers the task priority level.
<i>AllocatePages</i>	Allocates pages of a particular type.
<i>FreePages</i>	Frees allocated pages.
<i>GetMemoryMap</i>	Returns the current boot services memory map and memory map key.
<i>AllocatePool</i>	Allocates a pool of a particular type.
<i>FreePool</i>	Frees allocated pool.
<i>CreateEvent</i>	Creates a general-purpose event structure.
<i>SetTimer</i>	Sets an event to be signaled at a particular time.
<i>WaitForEvent</i>	Stops execution until an event is signaled.
<i>SignalEvent</i>	Signals an event.
<i>CloseEvent</i>	Closes and frees an event structure.
<i>CheckEvent</i>	Checks whether an event is in the signaled state.
<i>InstallProtocolInterface</i>	Installs a protocol interface on a device handle.
<i>ReinstallProtocolInterface</i>	Reinstalls a protocol interface on a device handle.
<i>UninstallProtocolInterface</i>	Removes a protocol interface from a device handle.
<i>HandleProtocol</i>	Queries a handle to determine if it supports a specified protocol.
<i>Reserved</i>	Reserved. Must be NULL .
<i>RegisterProtocolNotify</i>	Registers an event that is to be signaled whenever an interface is installed for a specified protocol.
<i>LocateHandle</i>	Returns an array of handles that support a specified protocol.
<i>LocateDevicePath</i>	Locates all devices on a device path that support a specified protocol and returns the handle to the device that is closest to the path.
<i>InstallConfigurationTable</i>	Adds, updates, or removes a configuration table from the EFI System Table.
<i>LoadImage</i>	Loads an EFI image into memory.
<i>StartImage</i>	Transfers control to a loaded image's entry point.
<i>Exit</i>	Exits the image's entry point.
<i>UnloadImage</i>	Unloads an image.
<i>ExitBootServices</i>	Terminates boot services.
<i>GetNextMonotonicCount</i>	Returns a monotonically increasing count for the platform.

<i>Stall</i>	Stalls the processor.
<i>SetWatchdogTimer</i>	Resets and sets a watchdog timer used during boot services time.
<i>ConnectController</i>	Uses a set of precedence rules to find the best set of drivers to manage a controller.
<i>DisconnectController</i>	Informs a set of drivers to stop managing a controller.
<i>OpenProtocol</i>	Adds elements to the list of agents consuming a protocol interface.
<i>CloseProtocol</i>	Removes elements from the list of agents consuming a protocol interface.
<i>OpenProtocolInformation</i>	Retrieve the list of agents that are currently consuming a protocol interface.
<i>ProtocolsPerHandle</i>	Retrieves the list of protocols installed on a handle. The return buffer is automatically allocated.
<i>LocateHandleBuffer</i>	Retrieves the list of handles from the handle database that meet the search criteria. The return buffer is automatically allocated.
<i>LocateProtocol</i>	Finds the first handle in the handle database the supports the requested protocol.
<i>InstallMultipleProtocolInterfaces</i>	Installs one or more protocol interfaces onto a handle.
<i>UninstallMultipleProtocolInterfaces</i>	Uninstalls one or more protocol interfaces from a handle.
<i>CalculateCrc32</i>	Computes and returns a 32-bit CRC for a data buffer.
<i>CopyMem</i>	Copies the contents of one buffer to another buffer.
<i>SetMem</i>	Fills a buffer with a specified value.
<i>CreateEventEx</i>	Creates an event structure as part of an event group.

4.5 EFI Runtime Services Table

UEFI uses the EFI Runtime Services Table, which contains a table header and pointers to all of the runtime services. The definition for this table is shown in the following code fragments. Except for the table header, all elements in the EFI Runtime Services Tables are prototypes of function pointers to functions as defined in [Section 7](#). Unlike the EFI Boot Services Table, this table, and the function pointers it contains are valid after the UEFI OS loader and OS have taken control of the platform with a call to [EFI_BOOT_SERVICES.ExitBootServices\(\)](#). If a call to [SetVirtualAddressMap\(\)](#) is made by the OS, then the function pointers in this table are fixed up to point to the new virtually mapped entry points.

EFI_RUNTIME_SERVICES

Summary

Contains a table header and pointers to all of the runtime services.

Related Definitions

```

#define EFI_RUNTIME_SERVICES_SIGNATURE 0x56524553544e5552

    //
    // Miscellaneous UEFI 2.0 Service
    //
    EFI_QUERY_VARIABLE_INFO    QueryVariableInfo;
} EFI_RUNTIME_SERVICES;

```

Parameters

<i>Hdr</i>	The table header for the EFI Runtime Services Table. This header contains the EFI_RUNTIME_SERVICES_SIGNATURE and EFI_RUNTIME_SERVICES_REVISION values along with the size of the EFI_RUNTIME_SERVICES structure and a 32-bit CRC to verify that the contents of the EFI Runtime Services Table are valid.
<i>GetTime</i>	Returns the current time and date, and the time-keeping capabilities of the platform.
<i>SetTime</i>	Sets the current local time and date information.
<i>GetWakeupTime</i>	Returns the current wakeup alarm clock setting.
<i>SetWakeupTime</i>	Sets the system wakeup alarm clock time.
<i>SetVirtualAddressMap</i>	Used by a UEFI OS loader to convert from physical addressing to virtual addressing.
<i>ConvertPointer</i>	Used by EFI components to convert internal pointers when switching to virtual addressing.
<i>GetVariable</i>	Returns the value of a variable.
<i>GetNextVariableName</i>	Enumerates the current variable names.
<i>SetVariable</i>	Sets the value of a variable.
<i>GetNextHighMonotonicCount</i>	Returns the next high 32 bits of the platform's monotonic counter.
<i>ResetSystem</i>	Resets the entire platform.
<i>UpdateCapsule</i>	Passes capsules to the firmware with both virtual and physical mapping.
<i>QueryCapsuleCapabilities</i>	Returns if the capsule can be supported via UpdateCapsule() .
<i>QueryVariableInfo</i>	Returns information about the EFI variable store.

4.6 EFI Configuration Table & Properties Table

The EFI Configuration Table is the *ConfigurationTable* field in the EFI System Table. This table contains a set of GUID/pointer pairs. Each element of this table is described by the **EFI_CONFIGURATION_TABLE** structure below. The number of types of configuration tables is expected to grow over time. This is why a GUID is used to identify the configuration table type. The EFI Configuration Table may contain at most once instance of each table type.

EFI_CONFIGURATION_TABLE

Summary

Contains a set of GUID/pointer pairs comprised of the *ConfigurationTable* field in the EFI System Table.

Related Definitions

```
typedef struct{
    EFI_GUID          VendorGuid;
    VOID              *VendorTable;
} EFI_CONFIGURATION_TABLE;
```

Parameters

The following list shows the GUIDs for tables defined in some of the industry standards. These industry standards define tables accessed as UEFI Configuration Tables on UEFI-based systems. This list is not exhaustive and does not show GUIDS for all possible UEFI Configuration tables.

<i>VendorGuid</i>	The 128-bit GUID value that uniquely identifies the system configuration table.
<i>VendorTable</i>	A pointer to the table associated with <i>VendorGuid</i> . Whether this pointer is a physical address or a virtual address during runtime is determined by the <i>VendorGuid</i> . The <i>VendorGuid</i> associated with a given <i>VendorTable</i> pointer defines whether or not a particular address reported in the table gets fixed up when a call to SetVirtualAddressMap() is made. It is the responsibility of the specification defining the <i>VendorTable</i> to specify whether to convert the addresses reported in the table.

The following list shows the GUIDs for tables defined in some of the industry standards. These industry standards define tables accessed as UEFI Configuration Tables on UEFI-based systems. All the addresses reported in these table entries will be referenced as physical and will not be fixed up when transition from preboot to runtime phase. This list is not exhaustive and does not show GUIDS for all possible UEFI Configuration tables.

```

#define EFI_ACPI_20_TABLE_GUID \

     {0xbc,0x22,0x00,0x80,0xc7,0x3c,0x88,0x81}}

#define ACPI_10_TABLE_GUID \
    {0xeb9d2d30,0x2d88,0x11d3,\
     {0x9a,0x16,0x00,0x90,0x27,0x3f,0xc1,0x4d}}

#define EFI_PROPERTIES_TABLE_GUID \
    {0x880aaca3, 0x4adc, 0x4a04,\
     {0x90,0x79,0xb7,0x47,0x34,0x8,0x25,0xe5}}

```

EFI_PROPERTIES_TABLE

This table is published if the platform meets some of the construction requirements listed in the *MemoryProtectionAttributes*.

```
typedef struct {
    UINT32    Version;
    UINT32    Length;
    UINT64    MemoryProtectionAttribute;
} EFI_PROPERTIES_TABLE;
```

Version This is revision of the table. Successive version may populate additional bits and growth the table length. In the case of the latter, the *Length* field will be adjusted appropriately

```
#define EFI_PROPERTIES_TABLE_VERSION 0x00010000
```

Length This is the size of the entire **EFI_PROPERTIES_TABLE** structure, including the version. The initial version will be of length 16.

MemoryProtectionAttribute

This field is a bit mask. Any bits not defined shall be considered reserved. A set bit means that the underlying firmware has been constructed responsive to the given property.

```
//
// Memory attribute (Not defined bits are reserved)
//
#define
EFI_PROPERTIES_RUNTIME_MEMORY_PROTECTION_NON_EXECUTABLE_PE_DATA
0x1 \
    // BIT 0 - description - implies the runtime data is separated
    from the code
```

This bit implies that the UEFI runtime code and data sections of the executable image are separate and must be aligned as specified in [Section 2.3](#). This bit also implies that the data pages do not have any executable code.

It is recommended not to use this attribute, especially for implementations that broke the runtime code memory map descriptors into the underlying code and data sections within UEFI modules. This splitting causes interoperability issues with operating systems that invoke **SetVirtualAddress()** without realizing that there is a relationship between these runtime descriptors.

EFI_MEMORY_ATTRIBUTES_TABLE

Summary

When published by the system firmware, the **EFI_MEMORY_ATTRIBUTES_TABLE** provides additional information about regions within the run-time memory blocks defined in the **EFI_MEMORY_DESCRIPTOR** entries returned from **EFI_BOOT_SERVICES.GetMemoryMap()** function. The Memory Attributes Table is currently used to describe memory protections that may be applied to the EFI Runtime code and data by an

operating system or hypervisor. Consumers of this table must currently ignore entries containing any values for *Type* except for *EfiRuntimeServicesData* and *EfiRuntimeServicesCode* to ensure compatibility with future uses of this table. The Memory Attributes Table may define multiple entries to describe sub-regions that comprise a single entry returned by **GetMemoryMap()** however the sub-regions must total to completely describe the larger region and may not cross boundaries between entries reported by **GetMemoryMap()**. If a run-time region returned in **GetMemoryMap()** entry is not described within the Memory Attributes Table, this region is assumed to not be compatible with any memory protections.

Only entire **EFI_MEMORY_DESCRIPTOR** entries as returned by **GetMemoryMap()** may be passed to **SetVirtualAddressMap()**.

Prototype

```
#define EFI_MEMORY_ATTRIBUTES_TABLE_GUID \
{ 0xdcfa911d, 0x26eb, 0x469f, \
  {0xa2, 0x20, 0x38, 0xb7, 0xdc, 0x46, 0x12, 0x20}}
```

With the following data structure

```
/* *****
/*   EFI_MEMORY_ATTRIBUTES_TABLE
/* *****
typedef struct {
    UINT32          Version ;
    UINT32          NumberOfEntries ;
    UINT32          DescriptorSize ;
    UINT32          Reserved;
    // EFI_MEMORY_DESCRIPTOR      Entry [1];
} EFI_MEMORY_ATTRIBUTES_TABLE;
```

<i>Version</i>	The version of this table. Present version is 0x00000001
<i>NumberOfEntries</i>	Count of EFI_MEMORY_DESCRIPTOR entries provided. This is typically the total number of PE/COFF sections within all UEFI modules that comprise the UEFI Runtime and all UEFI Runtime Data regions (e.g. runtime heap).
<i>Entry</i>	Array of <i>Entries</i> of type EFI_MEMORY_DESCRIPTOR .
<i>DescriptorSize</i>	Size of the memory descriptor.
<i>Reserved</i>	Reserved bytes.

Description

For each array entry, the **EFI_MEMORY_DESCRIPTOR.Attribute** field can inform a runtime agency, such as operating system or hypervisor, as to what class of protection settings can be made in the memory management unit for the memory defined by this entry. The only valid bits for *Attribute* field currently are **EFI_MEMORY_RO**, **EFI_MEMORY_XP**, plus **EFI_MEMORY_RUNTIME**. Irrespective of the memory

protections implied by *Attribute*, the **EFI_MEMORY_DESCRIPTOR.Type** field should match the type of the memory in enclosing **SetMemoryMap()** entry. *PhysicalStart* must be aligned as specified in [Section 2.3](#). The list must be sorted by physical start address in ascending order. *VirtualStart* field must be zero and ignored by the OS since it has no purpose for this table. *NumPages* must cover the entire memory region for the protection mapping. Each Descriptor in the **EFI_MEMORY_ATTRIBUTES_TABLE** with attribute **EFI_MEMORY_RUNTIME** must not overlap any other Descriptor in the **EFI_MEMORY_ATTRIBUTES_TABLE** with attribute **EFI_MEMORY_RUNTIME**. Additionally, every memory region described by a Descriptor in **EFI_MEMORY_ATTRIBUTES_TABLE** must be a sub-region of, or equal to, a descriptor in the table produced by **GetMemoryMap()**.

Table 13. Usage of Memory Attribute Definitions

	EFI_MEMORY_RO	EFI_MEMORY_XP	EFI_MEMORY_RUNTIME
No memory access protection is possible for Entry	0	0	1
Write-protected Code	1	0	1
Read/Write Data	0	1	1
Read-only Data	1	1	1

4.7 Image Entry Point Examples

The examples in the following sections show how the various table examples are presented in the UEFI environment.

4.7.1 Image Entry Point Examples

The following example shows the image entry point for a UEFI Application. This application makes use of the EFI System Table, the EFI Boot Services Table, and the EFI Runtime Services Table.

```

EFI_SYSTEM_TABLE          *gST;
EFI_BOOT_SERVICES         *gBS;
EFI_RUNTIME_SERVICES      *gRT;

EfiApplicationEntryPoint (
    IN EFI_HANDLE          ImageHandle,
    IN EFI_SYSTEM_TABLE    *SystemTable
)
{
    EFI_STATUS  Status;
    EFI_TIME    *Time;

    gST = SystemTable;
    gBS = gST->BootServices;
    gRT = gST->RuntimeServices;

```

```

//
// Use EFI System Table to print "Hello World" to the active console output
// device.
//
Status = gST->ConOut->OutputString (gST->ConOut, L"Hello World\n\r");
if (EFI_ERROR (Status)) {
    return Status;
}

//
// Use EFI Boot Services Table to allocate a buffer to store the current time
// and date.
//
Status = gBS->AllocatePool (
    EfiBootServicesData,
    sizeof (EFI_TIME),
    (VOID **)&Time
);
if (EFI_ERROR (Status)) {
    return Status;
}

//
// Use the EFI Runtime Services Table to get the current time and date.
//
Status = gRT->GetTime (Time, NULL)
if (EFI_ERROR (Status)) {
    return Status;
}

return Status;
}

```

The following example shows the UEFI image entry point for a driver that does not follow the UEFI *Driver Model*. Since this driver returns **EFI_SUCCESS**, it will stay resident in memory after it exits.

```

EFI_SYSTEM_TABLE                *gST;
EFI_BOOT_SERVICES                *gBS;
EFI_RUNTIME_SERVICES            *gRT;

EfiDriverEntryPoint(
    IN EFI_HANDLE                ImageHandle,
    IN EFI_SYSTEM_TABLE         *SystemTable
)
{
    gST = SystemTable;
    gBS = gST->BootServices;
    gRT = gST->RuntimeServices;

    //
    // Implement driver initialization here.
    //

    return EFI_SUCCESS;
}

```

The following example shows the UEFI image entry point for a driver that also does not follow the UEFI *Driver Model*. Since this driver returns **EFI_DEVICE_ERROR**, it will not stay resident in memory after it exits.

```

EFI_SYSTEM_TABLE          *gST;
EFI_BOOT_SERVICES        *gBS;
EFI_RUNTIME_SERVICES     *gRT;

EfiDriverEntryPoint(
    IN EFI_HANDLE          ImageHandle,
    IN EFI_SYSTEM_TABLE   *SystemTable
)
{
    gST = SystemTable;
    gBS = gST->BootServices;
    gRT = gST->RuntimeServices;

    //
    // Implement driver initialization here.
    //

    return EFI_DEVICE_ERROR;
}

```

4.7.2 UEFI Driver Model Example

The following is an UEFI *Driver Model* example that shows the driver initialization routine for the ABC device controller that is on the XYZ bus. The [EFI DRIVER BINDING PROTOCOL](#) and the function prototypes for [AbcSupported\(\)](#), [AbcStart\(\)](#), and [AbcStop\(\)](#) are defined in [Section 10.1](#). This function saves the driver's image handle and a pointer to the EFI boot services table in global variables, so the other functions in the same driver can have access to these values. It then creates an instance of the **EFI_DRIVER_BINDING_PROTOCOL** and installs it onto the driver's image handle.

```

extern EFI_GUID            gEfiDriverBindingProtocolGuid;
EFI_BOOT_SERVICES        *gBS;
static EFI_DRIVER_BINDING_PROTOCOL mAbcDriverBinding = {
    AbcSupported,
    AbcStart,
    AbcStop,
    1,
    NULL,
    NULL
};

AbcEntryPoint(
    IN EFI_HANDLE          ImageHandle,
    IN EFI_SYSTEM_TABLE   *SystemTable
)
{
    EFI_STATUS  Status;

    gBS = SystemTable->BootServices;

    mAbcDriverBinding->ImageHandle = ImageHandle;
}

```

```

mAbcDriverBinding->DriverBindingHandle = ImageHandle;

Status = gBS->InstallMultipleProtocolInterfaces(
    &mAbcDriverBinding->DriverBindingHandle,
    &gEfiDriverBindingProtocolGuid, &mAbcDriverBinding,
    NULL
);
return Status;
}

```

4.7.3 UEFI Driver Model Example (Unloadable)

The following is the same UEFI *Driver Model* example as above, except it also includes the code required to allow the driver to be unloaded through the boot service [Unload\(\)](#). Any protocols installed or memory allocated in [AbcEntryPoint\(\)](#) must be uninstalled or freed in the [AbcUnload\(\)](#).

```

extern EFI_GUID gEfiLoadedImageProtocolGuid;
extern EFI_GUID gEfiDriverBindingProtocolGuid;
EFI_BOOT_SERVICES *gBS;
static EFI_DRIVER_BINDING_PROTOCOL mAbcDriverBinding = {
    AbcSupported,
    AbcStart,
    AbcStop,
    1,
    NULL,
    NULL
};

EFI_STATUS
AbcUnload (
    IN EFI_HANDLE ImageHandle
);

AbcEntryPoint (
    IN EFI_HANDLE ImageHandle,
    IN EFI_SYSTEM_TABLE *SystemTable
)
{
    EFI_STATUS Status;
    EFI_LOADED_IMAGE_PROTOCOL *LoadedImage;

    gBS = SystemTable->BootServices;

    Status = gBS->OpenProtocol (
        ImageHandle,
        &gEfiLoadedImageProtocolGuid,
        &LoadedImage,
        ImageHandle,
        NULL,
        EFI_OPEN_PROTOCOL_GET_PROTOCOL
    );
    if (EFI_ERROR (Status)) {
        return Status;
    }
    LoadedImage->Unload = AbcUnload;

    mAbcDriverBinding->ImageHandle = ImageHandle;
    mAbcDriverBinding->DriverBindingHandle = ImageHandle;
}

```

```

    Status = gBS->InstallMultipleProtocolInterfaces(
        &mAbcDriverBinding->DriverBindingHandle,
        &gEfiDriverBindingProtocolGuid, &mAbcDriverBinding,
        NULL
    );

    return Status;
}

EFI_STATUS
AbcUnload (
    IN EFI_HANDLE ImageHandle
)
{
    EFI_STATUS Status;

    Status = gBS->UninstallMultipleProtocolInterfaces (
        ImageHandle,
        &gEfiDriverBindingProtocolGuid, &mAbcDriverBinding,
        NULL
    );
    return Status;
}

```

4.7.4 EFI Driver Model Example (Multiple Instances)

The following is the same as the first UEFI *Driver Model* example, except it produces three [EFI DRIVER BINDING PROTOCOL](#) instances. The first one is installed onto the driver's image handle. The other two are installed onto newly created handles.

```

extern EFI_GUID                gEfiDriverBindingProtocolGuid;
EFI_BOOT_SERVICES              *gBS;

static EFI_DRIVER_BINDING_PROTOCOL mAbcDriverBindingA = {
    AbcSupportedA,
    AbcStartA,
    AbcStopA,
    1,
    NULL,
    NULL
};

static EFI_DRIVER_BINDING_PROTOCOL mAbcDriverBindingB = {
    AbcSupportedB,
    AbcStartB,
    AbcStopB,
    1,
    NULL,
    NULL
};

static EFI_DRIVER_BINDING_PROTOCOL mAbcDriverBindingC = {
    AbcSupportedC,
    AbcStartC,
    AbcStopC,
    1,
    NULL,
    NULL
};

```

Unified Extensible Firmware Interface Specification

```
    NULL
};

AbcEntryPoint(
    IN EFI_HANDLE      ImageHandle,
    IN EFI_SYSTEM_TABLE *SystemTable
)
{
    EFI_STATUS Status;

    gBS = SystemTable->BootServices;

    //
    // Install mAbcDriverBindingA onto ImageHandle
    //
    mAbcDriverBindingA->ImageHandle      = ImageHandle;
    mAbcDriverBindingA->DriverBindingHandle = ImageHandle;

    Status = gBS->InstallMultipleProtocolInterfaces(
        &mAbcDriverBindingA->DriverBindingHandle,
        &gEfiDriverBindingProtocolGuid, &mAbcDriverBindingA,
        NULL
    );
    if (EFI_ERROR (Status)) {
        return Status;
    }

    //
    // Install mAbcDriverBindingB onto a newly created handle
    //
    mAbcDriverBindingB->ImageHandle      = ImageHandle;
    mAbcDriverBindingB->DriverBindingHandle = NULL;

    Status = gBS->InstallMultipleProtocolInterfaces(
        &mAbcDriverBindingB->DriverBindingHandle,
        &gEfiDriverBindingProtocolGuid, &mAbcDriverBindingB,
        NULL
    );
    if (EFI_ERROR (Status)) {
        return Status;
    }

    //
    // Install mAbcDriverBindingC onto a newly created handle
    //
    mAbcDriverBindingC->ImageHandle      = ImageHandle;
    mAbcDriverBindingC->DriverBindingHandle = NULL;

    Status = gBS->InstallMultipleProtocolInterfaces(
        &mAbcDriverBindingC->DriverBindingHandle,
        &gEfiDriverBindingProtocolGuid, &mAbcDriverBindingC,
        NULL
    );

    return Status;
}
```

GUID Partition Table (GPT) Disk Layout

5.1 GPT and MBR disk layout comparison

This specification defines the GUID Partition table (GPT) disk layout (i.e., partitioning scheme). The following list outlines the advantages of using the GPT disk layout over the legacy Master Boot Record (MBR) disk layout:

- Logical Block Addresses (LBAs) are 64 bits (rather than 32 bits).
- Supports many partitions (rather than just four primary partitions).
- Provides both a primary and backup partition table for redundancy.
- Uses version number and size fields for future expansion.
- Uses CRC32 fields for improved data integrity.
- Defines a GUID for uniquely identifying each partition.
- Uses a GUID and attributes to define partition content type.
- Each partition contains a 36 character human readable name.

5.2 LBA 0 Format

LBA 0 (i.e., the first logical block) of the hard disk contains either

- a legacy Master Boot Record (MBR) (see [Section 5.2.1](#))
- or a protective MBR (see [Section 5.2.3](#)).

5.2.1 Legacy Master Boot Record (MBR)

A legacy MBR may be located at LBA 0 (i.e., the first logical block) of the disk if it is not using the GPT disk layout (i.e., if it is using the MBR disk layout). The boot code on the MBR is not executed by UEFI firmware.

Table 14. Legacy MBR

Mnemonic	Byte Offset	Byte Length	Description
<i>BootCode</i>	0	424	x86 code used on a non-UEFI system to select an MBR partition record and load the first logical block of that partition . This code shall not be executed on UEFI systems.
<i>UniqueMBRDiskSignature</i>	440	4	Unique Disk Signature This may be used by the OS to identify the disk from other disks in the system. This value is always written by the OS and is never written by EFI firmware.

<i>Unknown</i>	444	2	Unknown. This field shall not be used by UEFI firmware.
<i>PartitionRecord</i>	446	16*4	Array of four legacy MBR partition records (see Table 15).
<i>Signature</i>	510	2	Set to 0xAA55 (i.e., byte 510 contains 0x55 and byte 511 contains 0xAA).
<i>Reserved</i>	512	Logical BlockSize - 512	The rest of the logical block, if any, is reserved.

The MBR contains four partition records (see Table 11) that each define the beginning and ending LBAs that a partition consumes on a disk.

Table 15. Legacy MBR Partition Record

Mnemonic	Byte Offset	Byte Length	Description
<i>BootIndicator</i>	0	1	0x80 indicates that this is the bootable legacy partition. Other values indicate that this is not a bootable legacy partition. This field shall not be used by UEFI firmware.
<i>StartingCHS</i>	1	3	Start of partition in CHS address format. This field shall not be used by UEFI firmware.
<i>OSType</i>	4	1	Type of partition. See Section 5.2.2 .
<i>EndingCHS</i>	5	3	End of partition in CHS address format. This field shall not be used by UEFI firmware.
<i>StartingLBA</i>	8	4	Starting LBA of the partition on the disk. This field is used by UEFI firmware to determine the start of the partition.
<i>SizeInLBA</i>	12	4	Size of the partition in LBA units of logical blocks. This field is used by UEFI firmware to determine the size of the partition.

If an MBR partition has an *OSType* field of 0xEF (i.e., UEFI System Partition), then the firmware must add the UEFI System Partition GUID to the handle for the MBR partition using **InstallProtocolInterface()**. This allows drivers and applications, including OS loaders, to easily search for handles that represent UEFI System Partitions. The following test must be performed to determine if a legacy MBR is valid:

- The Signature must be 0xaa55.
- A Partition Record that contains an *OSType* value of zero or a *SizeInLBA* value of zero may be ignored.

Otherwise:

- The partition defined by each MBR Partition Record must physically reside on the disk (i.e., not exceed the capacity of the disk).
- Each partition must not overlap with other partitions.

[Figure 16](#) shows an example of an MBR disk layout with four partitions.

Figure 16. MBRDisk Layout with legacy MBR example

5.2.2 OS Types

Unique types defined by this specification (other values are not defined by this specification):

- 0xEF (i.e., UEFI System Partition) defines a UEFI system partition.
- 0xEE (i.e., GPT Protective) is used by a protective MBR (see 5.2.2) to define a fake partition covering the entire disk.

Other values are used by legacy operating systems, and are allocated independently of the UEFI specification.

Note: “Partition types” by Andries Brouwer: See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “OS Type values used in the MBR disk layout”.

5.2.3 Protective MBR

A Protective MBR may be located at LBA 0 (i.e., the first logical block) of the disk if it is using the GPT disk layout. The Protective MBR precedes the GUID Partition Table Header to maintain compatibility with existing tools that do not understand GPT partition structures.

Table 16. Protective MBR

Mnemonic	Byte Offset	Byte Length	Contents
Boot Code	0	440	Unused by UEFI systems.
Unique MBR Disk Signature	440	4	Unused. Set to zero.
Unknown	444	2	Unused. Set to zero.
Partition Record	446	16*4	Array of four MBR partition records. Contains: <ul style="list-style-type: none"> • one partition record as defined Table 17; and • three partition records each set to zero.
Signature	510	2	Set to 0xAA55 (i.e., byte 510 contains 0x55 and byte 511 contains 0xAA).

Mnemonic	Byte Offset	Byte Length	Contents
Reserved	512	Logical Block Size - 512	The rest of the logical block, if any, is reserved. Set to zero.

One of the Partition Records shall be as defined in table 12, reserving the entire space on the disk after the Protective MBR itself for the GPT disk layout.

Table 17. Protective MBR Partition Record protecting the entire disk

Mnemonic	Byte Offset	Byte Length	Description
<i>BootIndicator</i>	0	1	Set to 0x00 to indicate a non-bootable partition. If set to any value other than 0x00 the behavior of this flag on non-UEFI systems is undefined. Must be ignored by UEFI implementations.
<i>StartingCHS</i>	1	3	Set to 0x000200, corresponding to the Starting LBA field.
<i>OSType</i>	4	1	Set to 0xEE (i.e., GPT Protective)
<i>EndingCHS</i>	5	3	Set to the CHS address of the last logical block on the disk. Set to 0xFFFFFFFF if it is not possible to represent the value in this field.
<i>StartingLBA</i>	8	4	Set to 0x00000001 (i.e., the LBA of the GPT Partition Header).
<i>SizeInLBA</i>	12	4	Set to the size of the disk minus one. Set to 0xFFFFFFFF if the size of the disk is too large to be represented in this field.

The remaining Partition Records shall each be set to zeros.

[Figure 17](#) shows an example of a GPT disk layout with four partitions with a protective MBR.

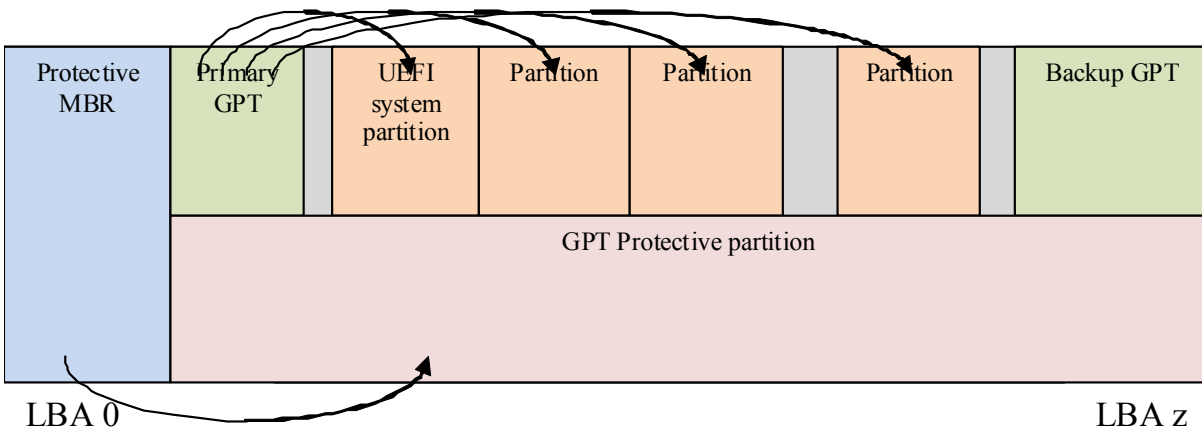

Figure 17. GPT disk layout with protective MBR example

Figure 18 shows an example of a GPT disk layout with four partitions with a protective MBR, where the disk capacity exceeds LBA 0xFFFFFFFF.

Figure 18. GPT disk layout with protective MBR on a disk with capacity exceeding LBA 0xFFFFFFFF example.

5.3 GUID Partition Table (GPT) Disk Layout

5.3.1 GPT overview

The GPT partitioning scheme is depicted in Figure 19. The GPT Header (see Section 5.3.2) includes a signature and a revision number that specifies the format of the data bytes in the partition header. The GUID Partition Table Header contains a header size field that is used in calculating the CRC32 that confirms the integrity of the GPT Header. While the GPT Header's size may increase in the future it cannot span more than one logical block on the device.

LBA 0 (i.e., the first logical block) contains a protective MBR (see [Section 5.2.3](#)).

Two GPT Header structures are stored on the device: the primary and the backup. The primary GPT Header must be located in LBA 1 (i.e., the second logical block), and the backup GPT Header must be located in the last LBA of the device. Within the GPT Header the *My LBA* field contains the LBA of the GPT Header itself, and the *Alternate LBA* field contains the LBA of the other GPT Header. For example, the primary GPT Header's *My LBA* value would be 1 and its *Alternate LBA* would be the value for the last LBA of the device. The backup GPT Header's fields would be reversed.

The GPT Header defines the range of LBAs that are usable by GPT Partition Entries. This range is defined to be inclusive of *First Usable LBA* through *Last Usable LBA* on the logical device. All data stored on the volume must be stored between the *First Usable LBA* through *Last Usable LBA*, and only the data structures defined by UEFI to manage partitions may reside outside of the usable space. The value of *Disk GUID* is a GUID that uniquely identifies the entire GPT Header and all its associated storage. This value can be used to uniquely identify the disk. The start of the GPT Partition Entry Array is located at the LBA indicated by the *Partition Entry LBA* field. The size of a GUID Partition Entry element is defined in the *Size Of Partition Entry* field. There is a 32-bit CRC of the GPT Partition Entry Array that is stored in the GPT Header in *Partition Entry Array CRC32* field. The size of the GPT Partition Entry Array is *Size Of Partition Entry* multiplied by *Number Of Partition Entries*. If the size of the GUID Partition Entry Array is not an even multiple of the logical block size, then any space left over in the last logical block is Reserved and not covered by the *Partition Entry Array CRC32* field. When a GUID Partition Entry is updated, the *Partition Entry Array CRC32* must be updated. When the *Partition Entry Array CRC32* is updated, the GPT Header CRC must also be updated, since the *Partition Entry Array CRC32* is stored in the GPT Header.

OM13160

Figure 19. GUID Partition Table (GPT) example

The primary GPT Partition Entry Array must be located after the primary GPT Header and end before the *First Usable LBA*. The backup GPT Partition Entry Array must be located after the *Last Usable LBA* and end before the backup GPT Header.

Therefore the primary and backup GPT Partition Entry Arrays are stored in separate locations on the disk. Each GPT Partition Entry defines a partition that is contained in a range that is within the usable space declared by the GPT Header. Zero or more GPT Partition Entries may be in use in the GPT Partition Entry Array. Each defined partition must not overlap with any other defined partition. If all the fields of a GUID Partition Entry are zero, the entry is not in use. A minimum of 16,384 bytes of space must be reserved for the GPT Partition Entry Array.

If the block size is 512, the *First Usable LBA* must be greater than or equal to 34 (allowing 1 block for the Protective MBR, 1 block for the Partition Table Header, and 32 blocks for the GPT Partition Entry Array); if the logical block size is 4096, the *First Usable LBA* must be greater than or equal to 6 (allowing 1 block for the Protective MBR, 1 block for the GPT Header, and 4 blocks for the GPT Partition Entry Array).

The device may present a logical block size that is not 512 bytes long. In ATA, this is called the Long Logical Sector feature set; an ATA device reports support for this feature set in IDENTIFY DEVICE data word 106 bit 12 and reports the number of words (i.e., 2 bytes) per logical sector in IDENTIFY DEVICE data words 117-118 (see ATA8-ACS). A SCSI device reports its logical block size in the READ CAPACITY parameter data Block Length In Bytes field (see SBC-3).

The device may present a logical block size that is smaller than the physical block size (e.g., present a logical block size of 512 bytes but implement a physical block size of 4,096 bytes). In ATA, this is called the Long Physical Sector feature set; an ATA device reports support for this feature set in IDENTIFY DEVICE data word 106 bit 13 and reports the Physical Sector Size/Logical Sector Size exponential ratio in IDENTIFY DEVICE data word 106 bits 3-0 (See ATA8-ACS). A SCSI device reports its logical block size/physical block exponential ratio in the READ CAPACITY (16) parameter data Logical Blocks Per Physical Block Exponent field (see SBC-3). These fields return 2^x logical sectors per physical sector (e.g., 3 means $2^3=8$ logical sectors per physical sector).

A device implementing long physical blocks may present logical blocks that are not aligned to the underlying physical block boundaries. An ATA device reports the alignment of logical blocks within a physical block in IDENTIFY DEVICE data word 209 (see ATA8-ACS). A SCSI device reports its alignment in the READ CAPACITY (16) parameter data Lowest Aligned Logical Block Address field (see SBC-3). Note that the ATA and SCSI fields are defined differently (e.g., to make LBA 63 aligned, ATA returns a value of 1 while SCSI returns a value of 7).

In SCSI devices, the Block Limits VPD page Optimal Transfer Length Granularity field (see SBC-3) may also report a granularity that is important for alignment purposes (e.g., RAID controllers may return their RAID stripe depth in that field)

GPT partitions should be aligned to the larger of:

- a the physical block boundary, if any
- b the optimal transfer length granularity, if any.

For example

- a If the logical block size is 512 bytes, the physical block size is 4,096 bytes (i.e., 512 bytes x 8 logical blocks), there is no optimal transfer length granularity, and logical block 0 is

aligned to a physical block boundary, then each GPT partition should start at an LBA that is a multiple of 8.

- b If the logical block size is 512 bytes, the physical block size is 8,192 bytes (i.e., 512 bytes x 16 logical blocks), the optimal transfer length granularity is 65,536 bytes (i.e., 512 bytes x 128 logical blocks), and logical block 0 is aligned to a physical block boundary, then each GPT partition should start at an LBA that is a multiple of 128.

To avoid the need to determine the physical block size and the optimal transfer length granularity, software may align GPT partitions at significantly larger boundaries. For example, assuming logical block 0 is aligned, it may use LBAs that are multiples of 2,048 to align to 1,048,576 byte (1 MiB) boundaries, which supports most common physical block sizes and RAID stripe sizes.

5.3.2 GPT Header

[Table 18](#) defines the GPT Header.

Table 18. GPT Header

Mnemonic	Byte Offset	Byte Length	Description
<i>Signature</i>	0	8	Identifies EFI-compatible partition table header. This value must contain the ASCII string “EFI PART”, encoded as the 64-bit constant 0x5452415020494645.
<i>Revision</i>	8	4	The revision number for this header. This revision value is not related to the UEFI Specification version. This header is version 1.0, so the correct value is 0x00010000.
<i>HeaderSize</i>	12	4	Size in bytes of the GPT Header. The <i>HeaderSize</i> must be greater than or equal to 92 and must be less than or equal to the logical block size.
<i>HeaderCRC32</i>	16	4	CRC32 checksum for the GPT Header structure. This value is computed by setting this field to 0, and computing the 32-bit CRC for <i>HeaderSize</i> bytes.
<i>Reserved</i>	20	4	Must be zero.

Mnemonic	Byte Offset	Byte Length	Description
<i>MyLBA</i>	24	8	The LBA that contains this data structure.
<i>AlternateLBA</i>	32	8	LBA address of the alternate GPT Header.
<i>FirstUsableLBA</i>	40	8	The first usable logical block that may be used by a partition described by a GUID Partition Entry.
<i>LastUsableLBA</i>	48	8	The last usable logical block that may be used by a partition described by a GUID Partition Entry.
<i>DiskGUID</i>	56	16	GUID that can be used to uniquely identify the disk.
<i>PartitionEntryLBA</i>	72	8	The starting LBA of the GUID Partition Entry array.
<i>NumberOfPartitionEntries</i>	80	4	The number of Partition Entries in the GUID Partition Entry array.
<i>SizeOfPartitionEntry</i>	84	4	The size, in bytes, of each the GUID Partition Entry structures in the GUID Partition Entry array. This field shall be set to a value of 128×2^n where n is an integer greater than or equal to zero (e.g., 128, 256, 512, etc.). NOTE: Previous versions of this specification allowed any multiple of 8..
<i>PartitionEntryArrayCRC32</i>	88	4	The CRC32 of the GUID Partition Entry array. Starts at <i>PartitionEntryLBA</i> and is computed over a byte length of $NumberOfPartitionEntries * SizeOfPartitionEntry$.
<i>Reserved</i>	92	BlockSize – 92	The rest of the block is reserved by UEFI and must be zero.

The following test must be performed to determine if a GPT is valid:

- Check the Signature
- Check the Header CRC
- Check that the *MyLBA* entry points to the LBA that contains the GUID Partition Table
- Check the CRC of the GUID Partition Entry Array

If the GPT is the primary table, stored at LBA 1:

- Check the *AlternateLBA* to see if it is a valid GPT

If the primary GPT is corrupt, software must check the last LBA of the device to see if it has a valid GPT Header and point to a valid GPT Partition Entry Array. If it points to a valid GPT Partition Entry Array, then software should restore the primary GPT if allowed by platform policy settings (e.g. a platform may require a user to provide confirmation before restoring the table, or may allow the table to be restored automatically). Software must report whenever it restores a GPT.

Software should ask a user for confirmation before restoring the primary GPT and must report whenever it does modify the media to restore a GPT. If a GPT formatted disk is reformatted to the legacy MBR format by legacy software, the last logical block might not be overwritten and might still contain a stale GPT. If GPT-cognizant software then accesses the disk and honors the stale GPT, it will misinterpret the contents of the disk. Software may detect this scenario if the legacy MBR contains valid partitions rather than a protective MBR (see [Section 5.2.1](#)).

Any software that updates the primary GPT must also update the backup GPT. Software may update the GPT Header and GPT Partition Entry Array in any order, since all the CRCs are stored in the GPT Header. Software must update the backup GPT before the primary GPT, so if the size of device has changed (e.g. volume expansion) and the update is interrupted, the backup GPT is in the proper location on the disk

If the primary GPT is invalid, the backup GPT is used instead and it is located on the last logical block on the disk. If the backup GPT is valid it must be used to restore the primary GPT. If the primary GPT is valid and the backup GPT is invalid software must restore the backup GPT. If both the primary and backup GPTs are corrupted this block device is defined as not having a valid GUID Partition Header.

Both the primary and backup GPTs must be valid before an attempt is made to grow the size of a physical volume. This is due to the GPT recovery scheme depending on locating the backup GPT at the end of the device. A volume may grow in size when disks are added to a RAID device. As soon as the volume size is increased the backup GPT must be moved to the end of the volume and the primary and backup GPT Headers must be updated to reflect the new volume size.

5.3.3 GPT Partition Entry Array

The GPT Partition Entry Array contains an array of GPT Partition Entries. [Table 19](#) defines the GPT Partition Entry.

Table 19. GPT Partition Entry

Mnemonic	Byte Offset	Byte Length	Description
<i>PartitionTypeGUID</i>	0	16	Unique ID that defines the purpose and type of this Partition. A value of zero defines that this partition entry is not being used.
<i>UniquePartitionGUID</i>	16	16	GUID that is unique for every partition entry. Every partition ever created will have a unique GUID. This GUID must be assigned when the GPT Partition Entry is created. The GPT Partition Entry is created whenever the <i>NumberOfPartitionEntries</i> in the GPT Header is increased to include a larger range of addresses.

<i>StartingLBA</i>	32	8	Starting LBA of the partition defined by this entry.
<i>EndingLBA</i>	40	8	Ending LBA of the partition defined by this entry.
<i>Attributes</i>	48	8	Attribute bits, all bits reserved by UEFI (see Table 20).
<i>PartitionName</i>	56	72	Null-terminated string containing a human-readable name of the partition.
<i>Reserved</i>	128	<i>SizeOfPartitionEntry</i> - 128	The rest of the GPT Partition Entry, if any, is reserved by UEFI and must be zero.

The *SizeOfPartitionEntry* variable in the GPT Header defines the size of each GUID Partition Entry. Each partition entry contains a *Unique Partition GUID* value that uniquely identifies every partition that will ever be created. Any time a new partition entry is created a new GUID must be generated for that partition, and every partition is guaranteed to have a unique GUID. The partition is defined as all the logical blocks inclusive of the *StartingLBA* and *EndingLBA*.

The *PartitionTypeGUID* field identifies the contents of the partition. This GUID is similar to the *OS Type* field in the MBR. Each filesystem must publish its unique GUID. The *Attributes* field can be used by utilities to make broad inferences about the usage of a partition and is defined in [Table 20](#).

The firmware must add the *PartitionTypeGuid* to the handle of every active GPT partition using [EFI_BOOT_SERVICES.InstallProtocolInterface\(\)](#). This will allow drivers and applications, including OS loaders, to easily search for handles that represent EFI System Partitions or vendor specific partition types.

Software that makes copies of GPT-formatted disks and partitions must generate new *Disk GUID* values in the GPT Headers and new *Unique Partition GUID* values in each GPT Partition Entry. If GPT-cognizant software encounters two disks or partitions with identical GUIDs, results will be indeterminate.

Table 20. Defined GPT Partition Entry - Partition Type GUIDs

Description	GUID Value
Unused Entry	00000000-0000-0000-0000-000000000000
EFI System Partition	C12A7328-F81F-11D2-BA4B-00A0C93EC93B
Partition containing a legacy MBR	024DEE41-33E7-11D3-9D69-0008C781F39F

OS vendors need to generate their own Partition Type GUIDs to identify their partition types.

Table 21. Defined GPT Partition Entry - Attributes

Bits	Name	Description
------	------	-------------

Unified Extensible Firmware Interface Specification

Bit 0	Required Partition	If this bit is set, the partition is required for the platform to function. The owner/creator of the partition indicates that deletion or modification of the contents can result in loss of platform features or failure for the platform to boot or operate. The system cannot function normally if this partition is removed, and it should be considered part of the hardware of the system. Actions such as running diagnostics, system recovery, or even OS install or boot could potentially stop working if this partition is removed. Unless OS software or firmware recognizes this partition, it should never be removed or modified as the UEFI firmware or platform hardware may become non-functional.
Bit 1	No Block IO Protocol	If this bit is set, then firmware must not produce an EFI_BLOCK_IO_PROTOCOL device for this partition. See Section 12.3.2 for more details. By not producing an EFI_BLOCK_IO_PROTOCOL partition, file system mappings will not be created for this partition in UEFI.
Bit 2	Legacy BIOS Bootable	This bit is set aside by this specification to let systems with traditional PC-AT BIOS firmware implementations inform certain limited, special-purpose software running on these systems that a GPT partition may be bootable. For systems with firmware implementations conforming to this specification, the UEFI boot manager (see chapter 3) must ignore this bit when selecting a UEFI-compliant application, e.g., an OS loader (see 2.1.3). Therefore there is no need for this specification to define the exact meaning of this bit.
Bits 3-47		Undefined and must be zero. Reserved for expansion by future versions of the UEFI specification.
Bits 48-63		Reserved for GUID specific use. The use of these bits will vary depending on the <i>PartitionTypeGUID</i> . Only the owner of the <i>PartitionTypeGUID</i> is allowed to modify these bits. They must be preserved if Bits 0–47 are modified.

Services — Boot Services

This section discusses the fundamental boot services that are present in a compliant system. The services are defined by interface functions that may be used by code running in the UEFI environment. Such code may include protocols that manage device access or extend platform capability, as well as applications running in the preboot environment, and OS loaders.

Two types of services apply in an compliant system:

Boot Services	Functions that are available <i>before</i> a successful call to EFI_BOOT_SERVICES.ExitBootServices() . These functions are described in this section.
Runtime Services	Functions that are available <i>before and after</i> any call to ExitBootServices() . These functions are described in Section 7 .

During boot, system resources are owned by the firmware and are controlled through boot services interface functions. These functions can be characterized as “global” or “handle-based.” The term “global” simply means that a function accesses system services and is available on all platforms (since all platforms support all system services). The term “handle-based” means that the function accesses a specific device or device functionality and may not be available on some platforms (since some devices are not available on some platforms). Protocols are created dynamically. This section discusses the “global” functions and runtime functions; subsequent sections discuss the “handle-based.”

UEFI applications (including UEFI OS loaders) must use boot services functions to access devices and allocate memory. On entry, an Image is provided a pointer to a system table which contains the Boot Services dispatch table and the default handles for accessing the console. All boot services functionality is available until a UEFI OS loader loads enough of its own environment to take control of the system’s continued operation and then terminates boot services with a call to [**ExitBootServices\(\)**](#).

In principle, the [**ExitBootServices\(\)**](#) call is intended for use by the operating system to indicate that its loader is ready to assume control of the platform and all platform resource management. Thus boot services are available up to this point to assist the UEFI OS loader in preparing to boot the operating system. Once the UEFI OS loader takes control of the system and completes the operating system boot process, only runtime services may be called. Code other than the UEFI OS loader, however, may or may not choose to call [**ExitBootServices\(\)**](#). This choice may in part depend upon whether or not such code is designed to make continued use of boot services or the boot services environment.

The rest of this section discusses individual functions. Global boot services functions fall into these categories:

- Event, Timer, and Task Priority Services ([Section 6.1](#))
- Memory Allocation Services ([Section 6.2](#))
- Protocol Handler Services ([Section 6.3](#))

- Image Services ([Section 6.4](#))
- Miscellaneous Services ([Section 6.5](#))

6.1 Event, Timer, and Task Priority Services

The functions that make up the Event, Timer, and Task Priority Services are used during preboot to create, close, signal, and wait for events; to set timers; and to raise and restore task priority levels. See [Table 22](#).

Table 22. Event, Timer, and Task Priority Functions

Name	Type	Description
CreateEvent	Boot	Creates a general-purpose event structure
CreateEventEx	Boot	Creates an event structure as part of an event group
CloseEvent	Boot	Closes and frees an event structure
SignalEvent	Boot	Signals an event
WaitForEvent	Boot	Stops execution until an event is signaled
CheckEvent	Boot	Checks whether an event is in the signaled state
SetTimer	Boot	Sets an event to be signaled at a particular time
RaiseTPL	Boot	Raises the task priority level
RestoreTPL	Boot	Restores/lowers the task priority level

Execution in the boot services environment occurs at different task priority levels, or TPLs. The boot services environment exposes only three of these levels to UEFI applications and drivers:

- [TPL_APPLICATION](#), the lowest priority level
- [TPL_CALLBACK](#), an intermediate priority level
- [TPL_NOTIFY](#), the highest priority level

Tasks that execute at a higher priority level may interrupt tasks that execute at a lower priority level. For example, tasks that run at the **TPL_NOTIFY** level may interrupt tasks that run at the **TPL_APPLICATION** or **TPL_CALLBACK** level. While **TPL_NOTIFY** is the highest level exposed to the boot services applications, the firmware may have higher task priority items it deals with. For example, the firmware may have to deal with tasks of higher priority like timer ticks and internal devices. Consequently, there is a fourth TPL, [TPL_HIGH_LEVEL](#), designed for use exclusively by the firmware.

The intended usage of the priority levels is shown in [Table 23](#) from the lowest level (**TPL_APPLICATION**) to the highest level (**TPL_HIGH_LEVEL**). As the level increases, the duration of the code and the amount of blocking allowed decrease. Execution generally occurs at the **TPL_APPLICATION** level. Execution occurs at other levels as a direct result of the triggering of an event notification function (this is typically caused by the signaling of an event). During timer interrupts, firmware signals timer events when an event’s “trigger time” has expired. This allows event notification functions to interrupt lower priority code to check devices (for example). The notification function can signal other events as required. After all pending event notification functions execute, execution continues at the **TPL_APPLICATION** level.

Table 23. TPL Usage

Task Priority Level	Usage
TPL_APPLICATION	This is the lowest priority level. It is the level of execution which occurs when no event notifications are pending and which interacts with the user. User I/O (and blocking on User I/O) can be performed at this level. The boot manager executes at this level and passes control to other UEFI applications at this level.
TPL_CALLBACK	Interrupts code executing below TPL_CALLBACK level Long term operations (such as file system operations and disk I/O) can occur at this level.
TPL_NOTIFY	Interrupts code executing below TPL_NOTIFY level Blocking is not allowed at this level. Code executes to completion and returns. If code requires more processing, it needs to signal an event to wait to obtain control again at whatever level it requires. This level is typically used to process low level IO to or from a device.
(Firmware Interrupts)	This level is internal to the firmware It is the level at which internal interrupts occur. Code running at this level interrupts code running at the TPL_NOTIFY level (or lower levels). If the interrupt requires extended time to complete, firmware signals another event (or events) to perform the longer term operations so that other interrupts can occur.
TPL_HIGH_LEVEL	Interrupts code executing below TPL_HIGH_LEVEL This is the highest priority level. It is not interruptible (interrupts are disabled) and is used sparingly by firmware to synchronize operations that need to be accessible from any priority level. For example, it must be possible to signal events while executing at any priority level. Therefore, firmware manipulates the internal event structure while at this priority level.

Executing code can temporarily raise its priority level by calling the [EFI_BOOT_SERVICES.RaiseTPL\(\)](#) function. Doing this masks event notifications from code running at equal or lower priority levels until the [EFI_BOOT_SERVICES.RestoreTPL\(\)](#) function is called to reduce the priority to a level below that of the pending event notifications. There are restrictions on the TPL levels at which many UEFI service functions and protocol interface functions can execute. [Table 24](#) summarizes the restrictions.

EFI_BOOT_SERVICES.CreateEvent()

Summary

Creates an event.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_CREATE_EVENT) (
    IN UINT32                Type,
    IN EFI_TPL               NotifyTpl,
    IN EFI_EVENT_NOTIFY     NotifyFunction, OPTIONAL
    IN VOID                  *NotifyContext, OPTIONAL
    OUT EFI_EVENT           *Event
);
```

Parameters

<i>Type</i>	The type of event to create and its mode and attributes. The #define statements in “Related Definitions” can be used to specify an event’s mode and attributes.
<i>NotifyTpl</i>	The task priority level of event notifications, if needed. See EFI_BOOT_SERVICES.RaiseTPL() .
<i>NotifyFunction</i>	Pointer to the event’s notification function, if any. See “Related Definitions.”
<i>NotifyContext</i>	Pointer to the notification function’s context; corresponds to parameter <i>Context</i> in the notification function.
<i>Event</i>	Pointer to the newly created event if the call succeeds; undefined otherwise.

Related Definitions

```
/**
//*****
// EFI_EVENT
//*****
typedef VOID *EFI_EVENT

//*****
// Event Types
//*****
// These types can be "ORed" together as needed - for example,
// EVT_TIMER might be "ORed" with EVT_NOTIFY_WAIT or
// EVT_NOTIFY_SIGNAL.
#define EVT_TIMER                0x80000000
#define EVT_RUNTIME              0x40000000

#define EVT_NOTIFY_WAIT         0x00000100
```

```
#define EVT_NOTIFY_SIGNAL                0x00000200

#define EVT_SIGNAL_EXIT_BOOT_SERVICES    0x00000201
#define EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE 0x60000202
```

EVT_TIMER The event is a timer event and may be passed to [EFI_BOOT_SERVICES.SetTimer\(\)](#). Note that timers only function during boot services time.

EVT_RUNTIME The event is allocated from runtime memory. If an event is to be signaled after the call to [EFI_BOOT_SERVICES.ExitBootServices\(\)](#), the event's data structure and notification function need to be allocated from runtime memory. For more information, see [SetVirtualAddressMap\(\)](#).

EVT_NOTIFY_WAIT If an event of this type is not already in the signaled state, then the event's *NotificationFunction* will be queued at the event's *NotifyTpl* whenever the event is being waited on via [EFI_BOOT_SERVICES.WaitForEvent\(\)](#) or [EFI_BOOT_SERVICES.CheckEvent\(\)](#).

EVT_NOTIFY_SIGNAL The event's *NotifyFunction* is queued whenever the event is signaled.

EVT_SIGNAL_EXIT_BOOT_SERVICES This event is to be notified by the system when [ExitBootServices\(\)](#) is invoked. This event is of type **EVT_NOTIFY_SIGNAL** and should not be combined with any other event types. The notification function for this event is not allowed to use the Memory Allocation Services, or call any functions that use the Memory Allocation Services and must only call functions that are known not to use Memory Allocation Services, because these services modify the current memory map. The notification function must not depend on timer events since timer services will be deactivated before any notification functions are called.

EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE The event is to be notified by the system when [SetVirtualAddressMap\(\)](#) is performed. This event type is a composite of **EVT_NOTIFY_SIGNAL**, **EVT_RUNTIME**, and **EVT_RUNTIME_CONTEXT** and should not be combined with any other event types.

```
/**/
// EFI_EVENT_NOTIFY
/**/
typedef
VOID
(EFI_API *EFI_EVENT_NOTIFY) (
    IN EFI_EVENT Event,
```

```

    IN VOID          *Context
    );

Event               Event whose notification function is being invoked.
Context             Pointer to the notification function's context, which is
                   implementation-dependent. Context corresponds to
                   NotifyContext in
                   EFI\_BOOT\_SERVICES.CreateEventEx\(\).

```

Description

The **CreateEvent()** function creates a new event of type *Type* and returns it in the location referenced by *Event*. The event's notification function, context, and task priority level are specified by *NotifyFunction*, *NotifyContext*, and *NotifyTpl*, respectively.

Events exist in one of two states, “waiting” or “signaled.” When an event is created, firmware puts it in the “waiting” state. When the event is signaled, firmware changes its state to “signaled” and, if **EVT_NOTIFY_SIGNAL** is specified, places a call to its notification function in a FIFO queue.

There is a queue for each of the “basic” task priority levels defined in [Section 6.1](#) (**TPL_CALLBACK**, and **TPL_NOTIFY**). The functions in these queues are invoked in FIFO order, starting with the highest priority level queue and proceeding to the lowest priority queue that is unmasked by the current TPL. If the current TPL is equal to or greater than the queued notification, it will wait until the TPL is lowered via [EFI_BOOT_SERVICES.RestoreTPL\(\)](#).

In a general sense, there are two “types” of events, synchronous and asynchronous. Asynchronous events are closely related to timers and are used to support periodic or timed interruption of program execution. This capability is typically used with device drivers. For example, a network device driver that needs to poll for the presence of new packets could create an event whose type includes **EVT_TIMER** and then call the [EFI_BOOT_SERVICES.SetTimer\(\)](#) function. When the timer expires, the firmware signals the event.

Synchronous events have no particular relationship to timers. Instead, they are used to ensure that certain activities occur following a call to a specific interface function. One example of this is the cleanup that needs to be performed in response to a call to the [EFI_BOOT_SERVICES.ExitBootServices\(\)](#) function. **ExitBootServices()** can clean up the firmware since it understands firmware internals, but it cannot clean up on behalf of drivers that have been loaded into the system. The drivers have to do that themselves by creating an event whose type is **EVT_SIGNAL_EXIT_BOOT_SERVICES** and whose notification function is a function within the driver itself. Then, when **ExitBootServices()** has finished its cleanup, it signals each event of type **EVT_SIGNAL_EXIT_BOOT_SERVICES**.

Another example of the use of synchronous events occurs when an event of type **EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE** is used in conjunction with the [SetVirtualAddressMap\(\)](#).

The **EVT_NOTIFY_WAIT** and **EVT_NOTIFY_SIGNAL** flags are exclusive. If neither flag is specified, the caller does not require any notification concerning the event and the *NotifyTpl*, *NotifyFunction*, and *NotifyContext* parameters are ignored. If **EVT_NOTIFY_WAIT** is specified and the event is not in the signaled state, then the **EVT_NOTIFY_WAIT** notify function is queued whenever a consumer of the event is waiting for the event (via [EFI_BOOT_SERVICES.WaitForEvent\(\)](#) or [EFI_BOOT_SERVICES.CheckEvent\(\)](#)).

If the **EVT_NOTIFY_SIGNAL** flag is specified then the event’s notify function is queued whenever the event is signaled.

Note: Because its internal structure is unknown to the caller, *Event* cannot be modified by the caller. The only way to manipulate it is to use the published event interfaces.

Status Codes Returned

EFI_SUCCESS	The event structure was created.
EFI_INVALID_PARAMETER	One of the parameters has an invalid value.
EFI_INVALID_PARAMETER	<i>Event</i> is NULL .
EFI_INVALID_PARAMETER	<i>Type</i> has an unsupported bit set.
EFI_INVALID_PARAMETER	<i>Type</i> has both EVT_NOTIFY_SIGNAL and EVT_NOTIFY_WAIT set.
EFI_INVALID_PARAMETER	<i>Type</i> has either EVT_NOTIFY_SIGNAL or EVT_NOTIFY_WAIT set and <i>NotifyFunction</i> is NULL .
EFI_INVALID_PARAMETER	Type has either EVT_NOTIFY_SIGNAL or EVT_NOTIFY_WAIT set and <i>NotifyTpl</i> is not a supported TPL level.
EFI_OUT_OF_RESOURCES	The event could not be allocated.

EFI_BOOT_SERVICES.CreateEventEx()

Summary

Creates an event in a group.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CREATE_EVENT_EX) (
    IN UINT32                Type,
    IN EFI_TPL               NotifyTpl,
    IN EFI_EVENT_NOTIFY     NotifyFunction OPTIONAL,
    IN CONST VOID           *NotifyContext OPTIONAL,
    IN CONST EFI_GUID       *EventGroup   OPTIONAL,
    OUT EFI_EVENT           *Event
);
```

Parameters

<i>Type</i>	The type of event to create and its mode and attributes.
<i>NotifyTpl</i>	The task priority level of event notifications, if needed. See EFI_BOOT_SERVICES.RaiseTPL() .
<i>NotifyFunction</i>	Pointer to the event's notification function, if any.
<i>NotifyContext</i>	Pointer to the notification function's context; corresponds to parameter <i>Context</i> in the notification function.
<i>EventGroup</i>	Pointer to the unique identifier of the group to which this event belongs. If this is NULL , then the function behaves as if the parameters were passed to CreateEvent .
<i>Event</i>	Pointer to the newly created event if the call succeeds; undefined otherwise.

Description

The **CreateEventEx** function creates a new event of type *Type* and returns it in the specified location indicated by *Event*. The event's notification function, context and task priority are specified by *NotifyFunction*, *NotifyContext*, and *NotifyTpl*, respectively. The event will be added to the group of events identified by *EventGroup*.

If no group is specified by *EventGroup*, then this function behaves as if the same parameters had been passed to **CreateEvent**.

Event groups are collections of events identified by a shared `EFI_GUID` where, when one member event is signaled, all other events are signaled and their individual notification actions are taken (as described in **CreateEvent**). All events are guaranteed to be signaled before the first notification action is taken. All notification functions will be executed in the order specified by their *NotifyTpl*.

A single event can only be part of a single event group. An event may be removed from an event group by using **CloseEvent**.

The *Type* of an event uses the same values as defined in **CreateEvent** except that **EVT_SIGNAL_EXIT_BOOT_SERVICES** and **EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE** are not valid.

If *Type* has **EVT_NOTIFY_SIGNAL** or **EVT_NOTIFY_WAIT**, then *NotifyFunction* must be non- **NULL** and *NotifyTpl* must be a valid task priority level. Otherwise these parameters are ignored.

More than one event of type **EVT_TIMER** may be part of a single event group. However, there is no mechanism for determining which of the timers was signaled.

Configuration Table Groups

The GUID for a configuration table also defines a corresponding event group GUID with the same value. If the data represented by a configuration table is changed, **InstallConfigurationTable()** should be called. When **InstallConfigurationTable()** is called, the corresponding event is signaled. When this event is signaled, any components that cache information from the configuration table can optionally update their cached state.

For example, **EFI_ACPI_TABLE_GUID** defines a configuration table for ACPI data. When ACPI data is changed, **InstallConfigurationTable()** is called. During the execution of **InstallConfigurationTable()**, a corresponding event group with **EFI_ACPI_TABLE_GUID** is signaled, allowing an application to invalidate any cached ACPI data.

Pre-Defined Event Groups

This section describes the pre-defined event groups used by the UEFI specification.

EFI_EVENT_GROUP_EXIT_BOOT_SERVICES

This event group is notified by the system when **ExitBootServices()** is invoked. The notification function for this event is not allowed to use the Memory Allocation Services, or call any functions that use the Memory Allocation Services, because these services modify the current memory map. The notification function must not depend on timer events since timer services will be deactivated before any notification functions are called. This is functionally equivalent to the **EVT_SIGNAL_EXIT_BOOT_SERVICES** flag for the *Type* argument of **CreateEvent**.

EFI_EVENT_GROUP_VIRTUAL_ADDRESS_CHANGE

This event group is notified by the system when **SetVirtualAddressMap()** is invoked. This is functionally equivalent to the **EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE** flag for the *Type* argument of **CreateEvent**.

EFI_EVENT_GROUP_MEMORY_MAP_CHANGE

This event group is notified by the system when the memory map has changed. The notification function for this event should not use Memory Allocation Services to avoid reentrancy complications.

EFI_EVENT_GROUP_READY_TO_BOOT

This event group is notified by the system when the Boot Manager is about to load and execute a boot option.

Related Definitions

EFI_EVENT is defined in **CreateEvent**.

EVT_SIGNAL_EXIT_BOOT_SERVICES and **EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE** are defined in **CreateEvent**.

```
#define EFI_EVENT_GROUP_EXIT_BOOT_SERVICES \
    {0x27abf055, 0xb1b8, 0x4c26, 0x80, 0x48, 0x74, 0x8f, 0x37, \
     0xba, 0xa2, 0xdf}}
```

```
#define EFI_EVENT_GROUP_VIRTUAL_ADDRESS_CHANGE \
    {0x13fa7698, 0xc831, 0x49c7, 0x87, 0xea, 0x8f, 0x43, 0xfc, \
     0xc2, 0x51, 0x96}
```

```
#define EFI_EVENT_GROUP_MEMORY_MAP_CHANGE \
    {0x78bee926, 0x692f, 0x48fd, 0x9e, 0xdb, 0x1, 0x42, 0x2e, \
     0xf0, 0xd7, 0xab}
```

```
#define EFI_EVENT_GROUP_READY_TO_BOOT \
    {0x7ce88fb3, 0x4bd7, 0x4679, 0x87, 0xa8, 0xa8, 0xd8, 0xde, \
     0xe5, 0xd, 0x2b}
```

Status Codes Returned

EFI_SUCCESS	The event structure was created.
EFI_INVALID_PARAMETER	One of the parameters has an invalid value.
EFI_INVALID_PARAMETER	<i>Event</i> is NULL .
EFI_INVALID_PARAMETER	<i>Type</i> has an unsupported bit set.
EFI_INVALID_PARAMETER	<i>Type</i> has both EVT_NOTIFY_SIGNAL and EVT_NOTIFY_WAIT set.
EFI_INVALID_PARAMETER	<i>Type</i> has either EVT_NOTIFY_SIGNAL or EVT_NOTIFY_WAIT set and <i>NotifyFunction</i> is NULL .
EFI_INVALID_PARAMETER	<i>Type</i> has either EVT_NOTIFY_SIGNAL or EVT_NOTIFY_WAIT set and <i>NotifyTpl</i> is not a supported TPL level.
EFI_OUT_OF_RESOURCES	The event could not be allocated.

EFI_BOOT_SERVICES.CloseEvent()

Summary

Closes an event.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CLOSE_EVENT) (
    IN EFI_EVENT Event
);
```

Parameters

Event The event to close. Type **EFI_EVENT** is defined in the [CreateEvent\(\)](#) function description.

Description

The **CloseEvent()** function removes the caller's reference to the event, removes it from any event group to which it belongs, and closes it. Once the event is closed, the event is no longer valid and may not be used on any subsequent function calls. If *Event* was registered with **RegisterProtocolNotify()** then **CloseEvent()** will remove the corresponding registration. It is safe to call **CloseEvent()** within the corresponding notify function.

Status Codes Returned

EFI_SUCCESS	The event has been closed.
-------------	----------------------------

EFI_BOOT_SERVICES.SignalEvent()

Summary

Signals an event.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_SIGNAL_EVENT) (
    IN EFI_EVENT Event
);
```

Parameters

Event The event to signal. Type **EFI_EVENT** is defined in the [EFI_BOOT_SERVICES.CheckEvent\(\)](#) function description.

Description

The supplied *Event* is placed in the signaled state. If *Event* is already in the signaled state, then **EFI_SUCCESS** is returned. If *Event* is of type **EVT_NOTIFY_SIGNAL**, then the event's notification function is scheduled to be invoked at the event's notification task priority level. **SignalEvent()** may be invoked from any task priority level.

If the supplied *Event* is a part of an event group, then all of the events in the event group are also signaled and their notification functions are scheduled.

When signaling an event group, it is possible to create an event in the group, signal it and then close the event to remove it from the group. For example:

```
EFI_EVENT Event;
EFI_GUID gMyEventGroupGuid = EFI_MY_EVENT_GROUP_GUID;
gBS->CreateEventEx (
    0,
    0,
    NULL,
    NULL,
    &gMyEventGroupGuid,
    &Event
);

gBS->SignalEvent (Event);
gBS->CloseEvent (Event);
```

Status Codes Returned

EFI_SUCCESS	The event was signaled.
-------------	-------------------------

EFI_BOOT_SERVICES.WaitForEvent()

Summary

Stops execution until an event is signaled.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_WAIT_FOR_EVENT) (
    IN UINTN      NumberOfEvents,
    IN EFI_EVENT  *Event,
    OUT UINTN     *Index
);
```

Parameters

<i>NumberOfEvents</i>	The number of events in the <i>Event</i> array.
<i>Event</i>	An array of EFI_EVENT . Type EFI_EVENT is defined in the CreateEvent() function description.
<i>Index</i>	Pointer to the index of the event which satisfied the wait condition.

Description

This function must be called at priority level **TPL_APPLICATION**. If an attempt is made to call it at any other priority level, **EFI_UNSUPPORTED** is returned.

The list of events in the *Event* array are evaluated in order from first to last, and this evaluation is repeated until an event is signaled or an error is detected. The following checks are performed on each event in the *Event* array.

- If an event is of type **EVT_NOTIFY_SIGNAL**, then **EFI_INVALID_PARAMETER** is returned and *Index* indicates the event that caused the failure.
- If an event is in the signaled state, the signaled state is cleared and **EFI_SUCCESS** is returned, and *Index* indicates the event that was signaled.
- If an event is not in the signaled state but does have a notification function, the notification function is queued at the event's notification task priority level. If the execution of the event's notification function causes the event to be signaled, then the signaled state is cleared, **EFI_SUCCESS** is returned, and *Index* indicates the event that was signaled.

To wait for a specified time, a timer event must be included in the *Event* array.

To check if an event is signaled without waiting, an already signaled event can be used as the last event in the list being checked, or the **CheckEvent()** interface may be used.

Status Codes Returned

EFI_SUCCESS	The event indicated by <i>Index</i> was signaled.
EFI_INVALID_PARAMETER	<i>NumberOfEvents</i> is 0.

EFI_INVALID_PARAMETER	The event indicated by <i>Index</i> is of type EVT_NOTIFY_SIGNAL .
EFI_UNSUPPORTED	The current TPL is not <u>TPL_APPLICATION</u> .

EFI_BOOT_SERVICES.CheckEvent()

Summary

Checks whether an event is in the signaled state.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CHECK_EVENT) (
    IN EFI_EVENT Event
);
```

Parameters

Event The event to check. Type **EFI_EVENT** is defined in the [CreateEvent\(\)](#) function description.

Description

The **CheckEvent()** function checks to see whether *Event* is in the signaled state. If *Event* is of type **EVT_NOTIFY_SIGNAL**, then **EFI_INVALID_PARAMETER** is returned. Otherwise, there are three possibilities:

- If *Event* is in the signaled state, it is cleared and **EFI_SUCCESS** is returned.
- If *Event* is not in the signaled state and has no notification function, **EFI_NOT_READY** is returned.
- If *Event* is not in the signaled state but does have a notification function, the notification function is queued at the event's notification task priority level. If the execution of the notification function causes *Event* to be signaled, then the signaled state is cleared and **EFI_SUCCESS** is returned; if the *Event* is not signaled, then **EFI_NOT_READY** is returned.

Status Codes Returned

EFI_SUCCESS	The event is in the signaled state.
EFI_NOT_READY	The event is not in the signaled state.
EFI_INVALID_PARAMETER	<i>Event</i> is of type EVT_NOTIFY_SIGNAL.

EFI_BOOT_SERVICES.SetTimer()

Summary

Sets the type of timer and the trigger time for a timer event.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SET_TIMER) (
    IN EFI_EVENT      Event,
    IN EFI_TIMER_DELAY Type,
    IN UINT64         TriggerTime
);
```

Parameters

<i>Event</i>	The timer event that is to be signaled at the specified time. Type EFI_EVENT is defined in the CreateEvent() function description.
<i>Type</i>	The type of time that is specified in <i>TriggerTime</i> . See the timer delay types in “Related Definitions.”
<i>TriggerTime</i>	The number of 100ns units until the timer expires. A <i>TriggerTime</i> of 0 is legal. If <i>Type</i> is TimerRelative and <i>TriggerTime</i> is 0, then the timer event will be signaled on the next timer tick. If <i>Type</i> is TimerPeriodic and <i>TriggerTime</i> is 0, then the timer event will be signaled on every timer tick.

Related Definitions

```

/*****
//EFI_TIMER_DELAY
/*****
typedef enum {
    TimerCancel,
    TimerPeriodic,
    TimerRelative
} EFI_TIMER_DELAY;
```

TimerCancel	The event’s timer setting is to be cancelled and no timer trigger is to be set. <i>TriggerTime</i> is ignored when canceling a timer.
TimerPeriodic	The event is to be signaled periodically at <i>TriggerTime</i> intervals from the current time. This is the only timer trigger <i>Type</i> for which the event timer does not need to be reset for each notification. All other timer trigger types are “one shot.”
TimerRelative	The event is to be signaled in <i>TriggerTime</i> 100ns units.

Description

The **SetTimer()** function cancels any previous time trigger setting for the event, and sets the new trigger time for the event. This function can only be used on events of type **EVT_TIMER**.

Status Codes Returned

EFI_SUCCESS	The event has been set to be signaled at the requested time.
EFI_INVALID_PARAMETER	<i>Event</i> or <i>Type</i> is not valid.

EFI_BOOT_SERVICES.RaiseTPL()

Summary

Raises a task's priority level and returns its previous level.

Prototype

```
typedef
EFI_TPL
(EFIAPI *EFI_RAISE_TPL) (
    IN EFI_TPL  NewTpl
);
```

Parameters

NewTpl

The new task priority level. It must be greater than or equal to the current task priority level. See “Related Definitions.”

Related Definitions

```

//*****
// EFI_TPL
//*****
typedef UINTN      EFI_TPL

//*****
// Task Priority Levels
//*****
#define TPL_APPLICATION      4
#define TPL_CALLBACK        8
#define TPL_NOTIFY          16
#define TPL_HIGH_LEVEL      31
```

Description

The [EFI_BOOT_SERVICES.RaiseTPL\(\)](#) function raises the priority of the currently executing task and returns its previous priority level.

Only three task priority levels are exposed outside of the firmware during boot services execution. The first is [TPL_APPLICATION](#) where all normal execution occurs. That level may be interrupted to perform various asynchronous interrupt style notifications, which occur at the [TPL_CALLBACK](#) or [TPL_NOTIFY](#) level. By raising the task priority level to [TPL_NOTIFY](#) such notifications are masked until the task priority level is restored, thereby synchronizing execution with such notifications. Synchronous blocking I/O functions execute at [TPL_NOTIFY](#). [TPL_CALLBACK](#) is the typically used for application level notification functions. Device drivers will typically use [TPL_CALLBACK](#) or [TPL_NOTIFY](#) for their notification functions. Applications and drivers may also use [TPL_NOTIFY](#) to protect data structures in critical sections of code.

The caller must restore the task priority level with [EFI_BOOT_SERVICES.RestoreTPL\(\)](#) to the previous level before returning.

Note: *If `NewTpl` is below the current TPL level, then the system behavior is indeterminate. Additionally, only `TPL_APPLICATION`, `TPL_CALLBACK`, `TPL_NOTIFY`, and `TPL_HIGH_LEVEL` may be used. All other values are reserved for use by the firmware; using them will result in unpredictable behavior. Good coding practice dictates that all code should execute at its lowest possible TPL level, and the use of TPL levels above `TPL_APPLICATION` must be minimized. Executing at TPL levels above `TPL_APPLICATION` for extended periods of time may also result in unpredictable behavior.*

Status Codes Returned

Unlike other UEFI interface functions, [EFI_BOOT_SERVICES.RaiseTPL\(\)](#) does not return a status code. Instead, it returns the previous task priority level, which is to be restored later with a matching call to `RestoreTPL()`.

EFI_BOOT_SERVICES.RestoreTPL()

Summary

Restores a task's priority level to its previous value.

Prototype

```
typedef
VOID
(EFI_API *EFI_RESTORE_TPL) (
    IN EFI_TPL  OldTpl
)
```

Parameters

OldTpl

The previous task priority level to restore (the value from a previous, matching call to [EFI_BOOT_SERVICES.RaiseTPL\(\)](#)). Type **EFI_TPL** is defined in the [RaiseTPL\(\)](#) function description.

Description

The [RestoreTPL\(\)](#) function restores a task's priority level to its previous value. Calls to [RestoreTPL\(\)](#) are matched with calls to [RaiseTPL\(\)](#).

Note: If *OldTpl* is above the current TPL level, then the system behavior is indeterminate. Additionally, only [TPL_APPLICATION](#), [TPL_CALLBACK](#), [TPL_NOTIFY](#), and [TPL_HIGH_LEVEL](#) may be used. All other values are reserved for use by the firmware; using them will result in unpredictable behavior. Good coding practice dictates that all code should execute at its lowest possible TPL level, and the use of TPL levels above [TPL_APPLICATION](#) must be minimized. Executing at TPL levels above [TPL_APPLICATION](#) for extended periods of time may also result in unpredictable behavior.

Status Codes Returned

None.

6.2 Memory Allocation Services

The functions that make up Memory Allocation Services are used during preboot to allocate and free memory, and to obtain the system's memory map. See [Table 25](#).

Table 25. Memory Allocation Functions

Name	Type	Description
AllocatePages	Boot	Allocates pages of a particular type.
FreePages	Boot	Frees allocated pages.
GetMemoryMap	Boot	Returns the current boot services memory map and memory map key.
AllocatePool	Boot	Allocates a pool of a particular type.

Name	Type	Description
FreePool	Boot	Frees allocated pool.

The way in which these functions are used is directly related to an important feature of UEFI memory design. This feature, which stipulates that EFI firmware owns the system's memory map during preboot, has three major consequences:

- During preboot, all components (including executing EFI images) must cooperate with the firmware by allocating and freeing memory from the system with the functions [EFI_BOOT_SERVICES.AllocatePages\(\)](#), [EFI_BOOT_SERVICES.AllocatePool\(\)](#), [EFI_BOOT_SERVICES.FreePages\(\)](#), and [EFI_BOOT_SERVICES.FreePool\(\)](#). The firmware dynamically maintains the memory map as these functions are called.
- During preboot, an executing EFI Image must only use the memory it has allocated.
- Before an executing EFI image exits and returns control to the firmware, it must free all resources it has explicitly allocated. This includes all memory pages, pool allocations, open file handles, etc. Memory allocated by the firmware to load an image is freed by the firmware when the image is unloaded.

When memory is allocated, it is “typed” according to the values in **EFI_MEMORY_TYPE** (see the description for [EFI_BOOT_SERVICES.AllocatePages\(\)](#)). Some of the types have a different usage *before* [EFI_BOOT_SERVICES.ExitBootServices\(\)](#) is called than they do *afterwards*. [Table 26](#) lists each type and its usage before the call; [Table 27](#) lists each type and its usage after the call. The system firmware must follow the processor-specific rules outlined in [Section 2.3.2](#) and [Section 2.3.4](#) in the layout of the EFI memory map to enable the OS to make the required virtual mappings.

Table 26. Memory Type Usage before `ExitBootServices()`

Mnemonic	Description
EfiReservedMemoryType	Not usable.
EfiLoaderCode	The code portions of a loaded UEFI application.
EfiLoaderData	The data portions of a loaded UEFI application and the default data allocation type used by a UEFI application to allocate pool memory.
EfiBootServicesCode	The code portions of a loaded UEFI Boot Service Driver.
EfiBootServicesData	The data portions of a loaded UEFI Boot Service Driver, and the default data allocation type used by a UEFI Boot Service Driver to allocate pool memory.
EfiRuntimeServicesCode	The code portions of a loaded UEFI Runtime Driver.
EfiRuntimeServicesData	The data portions of a loaded UEFI Runtime Driver and the default data allocation type used by a UEFI Runtime Driver to allocate pool memory.
EfiConventionalMemory	Free (unallocated) memory.
EfiUnusableMemory	Memory in which errors have been detected.
EfiACPIReclaimMemory	Memory that holds the ACPI tables.
EfiACPIMemoryNVS	Address space reserved for use by the firmware.

Mnemonic	Description
EfiMemoryMappedIO	Used by system firmware to request that a memory-mapped IO region be mapped by the OS to a virtual address so it can be accessed by EFI runtime services.
EfiMemoryMappedIOPortSpace	System memory-mapped IO region that is used to translate memory cycles to IO cycles by the processor.
EfiPalCode	Address space reserved by the firmware for code that is part of the processor.
EfiPersistentMemory	A memory region that operates as <i>EfiConventionalMemory</i> . However, it happens to also support byte-addressable non-volatility.

Note: *There is only one region of type `EfiMemoryMappedIoPortSpace` defined in the architecture for Itanium-based platforms. As a result, there should be one and only one region of type `EfiMemoryMappedIoPortSpace` in the EFI memory map of an Itanium-based platform.*

Table 27. Memory Type Usage after `ExitBootServices ()`

Mnemonic	Description
EfiReservedMemoryType	Not usable.
EfiLoaderCode	The UEFI OS Loader and/or OS may use this memory as they see fit. Note: the UEFI OS loader that called UEFI BOOT SERVICES.ExitBootServices () is utilizing one or more EfiLoaderCode ranges.
EfiLoaderData	The Loader and/or OS may use this memory as they see fit. Note: the OS loader that called ExitBootServices () is utilizing one or more EfiLoaderData ranges.
EfiBootServicesCode	Memory available for general use.
EfiBootServicesData	Memory available for general use.
EfiRuntimeServicesCode	The memory in this range is to be preserved by the UEFI OS loader and OS in the working and ACPI S1–S3 states.
EfiRuntimeServicesData	The memory in this range is to be preserved by the UEFI OS loader and OS in the working and ACPI S1–S3 states.
EfiConventionalMemory	Memory available for general use.
EfiUnusableMemory	Memory that contains errors and is not to be used.
EfiACPIReclaimMemory	This memory is to be preserved by the UEFI OS loader and OS until ACPI is enabled. Once ACPI is enabled, the memory in this range is available for general use.
EfiACPIMemoryNVS	This memory is to be preserved by the UEFI OS loader and OS in the working and ACPI S1–S3 states.
EfiMemoryMappedIO	This memory is not used by the OS. All system memory-mapped IO information should come from ACPI tables.
EfiMemoryMappedIOPortSpace	This memory is not used by the OS. All system memory-mapped IO port space information should come from ACPI tables.

Unified Extensible Firmware Interface Specification

EfiPalCode	This memory is to be preserved by the UEFI OS loader and OS in the working and ACPI S1–S4 states. This memory may also have other attributes that are defined by the processor implementation.
EfiPersistentMemory	A memory region that operates as <i>EfiConventionalMemory</i> . However, it happens to also support byte-addressable non-volatility.

Note: An image that calls **ExitBootServices()** (i.e., a UEFI OS Loader) first calls **EFI_BOOT_SERVICES.GetMemoryMap()** to obtain the current memory map. Following the **ExitBootServices()** call, the image implicitly owns all unused memory in the map. This includes memory types *EfiLoaderCode*, *EfiLoaderData*, *EfiBootServicesCode*, *EfiBootServicesData*, and *EfiConventionalMemory*. A UEFI OS Loader and OS must preserve the memory marked as *EfiRuntimeServicesCode* and *EfiRuntimeServicesData*.

EFI_BOOT_SERVICES.AllocatePages()

Summary

Allocates memory pages from the system.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_ALLOCATE_PAGES) (
    IN EFI_ALLOCATE_TYPE           Type,
    IN EFI_MEMORY_TYPE            MemoryType,
    IN UINTN                       Pages,
    IN OUT EFI_PHYSICAL_ADDRESS   *Memory
);
```

Parameters

<i>Type</i>	The type of allocation to perform. See “Related Definitions.”
<i>MemoryType</i>	The type of memory to allocate. The type EFI_MEMORY_TYPE is defined in “Related Definitions” below. These memory types are also described in more detail in Table 26 and Table 27 . Normal allocations (that is, allocations by any UEFI application) are of type EfiLoaderData . <i>MemoryType</i> values in the range 0x70000000..0x7FFFFFFF are reserved for OEM use. <i>MemoryType</i> values in the range 0x80000000..0xFFFFFFFF are reserved for use by UEFI OS loaders that are provided by operating system vendors.
<i>Pages</i>	The number of contiguous 4 KiB pages to allocate.
<i>Memory</i>	Pointer to a physical address. On input, the way in which the address is used depends on the value of <i>Type</i> . See “Description” for more information. On output the address is set to the base of the page range that was allocated. See “Related Definitions.”

Note: UEFI Applications, UEFI Drivers, and UEFI OS Loaders must not allocate memory of type **EfiReservedMemoryType**.

Related Definitions

```

//*****
//EFI_ALLOCATE_TYPE
//*****
// These types are discussed in the “Description” section below.
typedef enum {
    AllocateAnyPages,
    AllocateMaxAddress,
    AllocateAddress,
    MaxAllocateType
} EFI_ALLOCATE_TYPE;
```

```

//*****
//EFI_MEMORY_TYPE
//*****
// These type values are discussed in Table 26 and Table 27.
typedef enum {
    EfiReservedMemoryType,
    EfiLoaderCode,
    EfiLoaderData,
    EfiBootServicesCode,
    EfiBootServicesData,
    EfiRuntimeServicesCode,
    EfiRuntimeServicesData,
    EfiConventionalMemory,
    EfiUnusableMemory,
    EfiACPIReclaimMemory,
    EfiACPIMemoryNVS,
    EfiMemoryMappedIO,
    EfiMemoryMappedIOPortSpace,
    EfiPalCode,
    EfiPersistentMemory,
    EfiMaxMemoryType
} EFI_MEMORY_TYPE;

//*****
//EFI_PHYSICAL_ADDRESS
//*****
typedef UINT64 EFI_PHYSICAL_ADDRESS;

```

Description

The **AllocatePages ()** function allocates the requested number of pages and returns a pointer to the base address of the page range in the location referenced by *Memory*. The function scans the memory map to locate free pages. When it finds a physically contiguous block of pages that is large enough and also satisfies the allocation requirements of *Type*, it changes the memory map to indicate that the pages are now of type *MemoryType*.

In general, UEFI OS loaders and UEFI applications should allocate memory (and pool) of type **EfiLoaderData**. UEFI boot service drivers must allocate memory (and pool) of type **EfiBootServicesData**. UEFI runtime drivers should allocate memory (and pool) of type **EfiRuntimeServicesData** (although such allocation can only be made during boot services time).

Allocation requests of *Type* **AllocateAnyPages** allocate any available range of pages that satisfies the request. On input, the address pointed to by *Memory* is ignored.

Allocation requests of *Type* **AllocateMaxAddress** allocate any available range of pages whose uppermost address is less than or equal to the address pointed to by *Memory* on input.

Allocation requests of *Type* **AllocateAddress** allocate pages at the address pointed to by *Memory* on input.

Note: UEFI drivers and UEFI applications that are not targeted for a specific implementation must perform memory allocations for the following runtime types using **AllocateAnyPages** address mode:

EfiACPIReclaimMemory,
EfiACPIMemoryNVS,
EfiRuntimeServicesCode,
EfiRuntimeServicesData,
EfiReservedMemoryType.

Status Codes Returned

EFI_SUCCESS	The requested pages were allocated.
EFI_OUT_OF_RESOURCES	The pages could not be allocated.
EFI_INVALID_PARAMETER	<i>Type</i> is not AllocateAnyPages or AllocateMaxAddress or AllocateAddress .
EFI_INVALID_PARAMETER	<i>MemoryType</i> is in the range EfiMaxMemoryType ..0x6FFFFFFF.
EFI_INVALID_PARAMETER	<i>MemoryType</i> is EfiPersistentMemory .
EFI_INVALID_PARAMETER	<i>Memory</i> is NULL.
EFI_NOT_FOUND	The requested pages could not be found.

EFI_BOOT_SERVICES.FreePages()

Summary

Frees memory pages.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FREE_PAGES) (
    IN EFI_PHYSICAL_ADDRESS    Memory,
    IN UINTN                   Pages
);
```

Parameters

Memory

The base physical address of the pages to be freed. Type **EFI_PHYSICAL_ADDRESS** is defined in the [EFI_BOOT_SERVICES.AllocatePages\(\)](#) function description.

Pages

The number of contiguous 4 KiB pages to free.

Description

The **FreePages()** function returns memory allocated by **AllocatePages()** to the firmware.

Status Codes Returned

EFI_SUCCESS	The requested memory pages were freed.
EFI_NOT_FOUND	The requested memory pages were not allocated with AllocatePages() .
EFI_INVALID_PARAMETER	<i>Memory</i> is not a page-aligned address or <i>Pages</i> is invalid.

EFI_BOOT_SERVICES.GetMemoryMap()

Summary

Returns the current memory map.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_GET_MEMORY_MAP) (
    IN OUT UINTN                *MemoryMapSize,
    IN OUT EFI_MEMORY_DESCRIPTOR *MemoryMap,
    OUT UINTN                   *MapKey,
    OUT UINTN                   *DescriptorSize,
    OUT UINT32                  *DescriptorVersion
);
```

Parameters

<i>MemoryMapSize</i>	A pointer to the size, in bytes, of the <i>MemoryMap</i> buffer. On input, this is the size of the buffer allocated by the caller. On output, it is the size of the buffer returned by the firmware if the buffer was large enough, or the size of the buffer needed to contain the map if the buffer was too small.
<i>MemoryMap</i>	A pointer to the buffer in which firmware places the current memory map. The map is an array of EFI_MEMORY_DESCRIPTOR s. See “Related Definitions.”
<i>MapKey</i>	A pointer to the location in which firmware returns the key for the current memory map.
<i>DescriptorSize</i>	A pointer to the location in which firmware returns the size, in bytes, of an individual EFI_MEMORY_DESCRIPTOR .
<i>DescriptorVersion</i>	A pointer to the location in which firmware returns the version number associated with the EFI_MEMORY_DESCRIPTOR . See “Related Definitions.”

Related Definitions

```
/**
*****
//EFI_MEMORY_DESCRIPTOR
*****
typedef struct {
    UINT32                Type;
    EFI_PHYSICAL_ADDRESS  PhysicalStart;
    EFI_VIRTUAL_ADDRESS   VirtualStart;
    UINT64                NumberOfPages;
    UINT64                Attribute;
} EFI_MEMORY_DESCRIPTOR;
```

<i>Type</i>	Type of the memory region. Type EFI_MEMORY_TYPE is defined in the AllocatePages() function description.
<i>PhysicalStart</i>	Physical address of the first byte in the memory region. Physical start must be aligned on a 4 KiB boundary. Type EFI_PHYSICAL_ADDRESS is defined in the AllocatePages() function description.
<i>VirtualStart</i>	Virtual address of the first byte in the memory region. Virtual start must be aligned on a 4 KiB boundary. Type EFI_VIRTUAL_ADDRESS is defined in “Related Definitions.”
<i>NumberOfPages</i>	Number of 4 KiB pages in the memory region.
<i>Attribute</i>	Attributes of the memory region that describe the bit mask of capabilities for that memory region, and not necessarily the current settings for that memory region. See the following “Memory Attribute Definitions.”

```

//*****
// Memory Attribute Definitions
//*****
// These types can be "ORed" together as needed.
#define EFI_MEMORY_UC          0x0000000000000001
#define EFI_MEMORY_WC          0x0000000000000002
#define EFI_MEMORY_WT          0x0000000000000004
#define EFI_MEMORY_WB          0x0000000000000008
#define EFI_MEMORY_UCE         0x0000000000000010
#define EFI_MEMORY_WP          0x0000000000000100
#define EFI_MEMORY_RP          0x0000000000000200
#define EFI_MEMORY_XP          0x0000000000000400
#define EFI_MEMORY_NV          0x0000000000000800
#define EFI_MEMORY_MORE_RELIABLE 0x0000000000001000
#define EFI_MEMORY_RO          0x0000000000002000
#define EFI_MEMORY_RUNTIME     0x8000000000000000

```

EFI_MEMORY_UC	Memory cacheability attribute: The memory region supports being configured as not cacheable.
EFI_MEMORY_WC	Memory cacheability attribute: The memory region supports being configured as write combining.
EFI_MEMORY_WT	Memory cacheability attribute: The memory region supports being configured as cacheable with a “write through” policy. Writes that hit in the cache will also be written to main memory.
EFI_MEMORY_WB	Memory cacheability attribute: The memory region supports being configured as cacheable with a “write back” policy. Reads and writes that hit in the cache do not propagate to main memory. Dirty data is written back to main memory when a new cache line is allocated.
EFI_MEMORY_UCE	Memory cacheability attribute: The memory region supports being configured as not cacheable, exported, and supports the “fetch and add” semaphore mechanism.

EFI_MEMORY_WP Physical memory protection attribute: The memory region supports being configured as write-protected by system hardware. This is typically used as a cacheability attribute today. The memory region supports being configured as cacheable with a "write protected" policy. Reads come from cache lines when possible, and read misses cause cache fills. Writes are propagated to the system bus and cause corresponding cache lines on all processors on the bus to be invalidated.

Note: *UEFI spec 2.5 and following: use `EFI_MEMORY_RO` as write-protected physical memory protection attribute. Also, `EFI_MEMORY_WP` means cacheability attribute.*

EFI_MEMORY_RP Physical memory protection attribute: The memory region supports being configured as read-protected by system hardware.

EFI_MEMORY_XP Physical memory protection attribute: The memory region supports being configured so it is protected by system hardware from executing code.

EFI_MEMORY_NV Runtime memory attribute: The memory region refers to persistent memory

EFI_MEMORY_MORE_RELIABLE The memory region provides higher reliability relative to other memory in the system. If all memory has the same reliability, then this bit is not used.

EFI_MEMORY_RO Physical memory protection attribute: The memory region supports making this memory range read-only by system hardware.

EFI_MEMORY_RUNTIME Runtime memory attribute: The memory region needs to be given a virtual mapping by the operating system when [SetVirtualAddressMap\(\)](#) is called (described in [Section 7.4](#)).

```

//*****
//EFI_VIRTUAL_ADDRESS
//*****
typedef UINT64     EFI_VIRTUAL_ADDRESS;

//*****
// Memory Descriptor Version Number
//*****
#define EFI_MEMORY_DESCRIPTOR_VERSION 1

```

Description

The `GetMemoryMap()` function returns a copy of the current memory map. The map is an array of memory descriptors, each of which describes a contiguous block of memory. The map describes all of memory, no matter how it is being used. That is, it includes blocks allocated by [EFI_BOOT_SERVICES.AllocatePages\(\)](#) and

[EFI_BOOT_SERVICES.AllocatePool\(\)](#), as well as blocks that the firmware is using for its own purposes. The memory map is only used to describe memory that is present in the system. The firmware does not return a range description for address space regions that are not backed by physical hardware. Regions that are backed by physical hardware, but are not supposed to be accessed by the OS, must be returned as **EfiReservedMemoryType**. The OS may use addresses of memory ranges that are not described in the memory map at its own discretion.

Until [EFI_BOOT_SERVICES.ExitBootServices\(\)](#) is called, the memory map is owned by the firmware and the currently executing UEFI Image should only use memory pages it has explicitly allocated.

If the *MemoryMap* buffer is too small, the **EFI_BUFFER_TOO_SMALL** error code is returned and the *MemoryMapSize* value contains the size of the buffer needed to contain the current memory map. The actual size of the buffer allocated for the consequent call to **GetMemoryMap()** should be bigger than the value returned in *MemoryMapSize*, since allocation of the new buffer may potentially increase memory map size.

On success a *MapKey* is returned that identifies the current memory map. The firmware's key is changed every time something in the memory map changes. In order to successfully invoke [EFI_BOOT_SERVICES.ExitBootServices\(\)](#) the caller must provide the current memory map key.

The **GetMemoryMap()** function also returns the size and revision number of the **EFI_MEMORY_DESCRIPTOR**. The *DescriptorSize* represents the size in bytes of an **EFI_MEMORY_DESCRIPTOR** array element returned in *MemoryMap*. The size is returned to allow for future expansion of the **EFI_MEMORY_DESCRIPTOR** in response to hardware innovation. The structure of the **EFI_MEMORY_DESCRIPTOR** may be extended in the future but it will remain backwards compatible with the current definition. Thus OS software must use the *DescriptorSize* to find the start of each **EFI_MEMORY_DESCRIPTOR** in the *MemoryMap* array.

Status Codes Returned

EFI_SUCCESS	The memory map was returned in the <i>MemoryMap</i> buffer.
EFI_BUFFER_TOO_SMALL	The <i>MemoryMap</i> buffer was too small. The current buffer size needed to hold the memory map is returned in <i>MemoryMapSize</i> .
EFI_INVALID_PARAMETER	<i>MemoryMapSize</i> is NULL .
EFI_INVALID_PARAMETER	The <i>MemoryMap</i> buffer is not too small and <i>MemoryMap</i> is NULL .

EFI_BOOT_SERVICES.AllocatePool()

Summary

Allocates pool memory.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ALLOCATE_POOL) (
    IN EFI_MEMORY_TYPE  PoolType,
    IN UINTN             Size,
    OUT VOID             **Buffer
);
```

Parameters

PoolType

The type of pool to allocate. Type **EFI_MEMORY_TYPE** is defined in the [EFI_BOOT_SERVICES.AllocatePages\(\)](#) function description. *PoolType* values in the range 0x70000000..0x7FFFFFFF are reserved for OEM use. *PoolType* values in the range 0x80000000..0xFFFFFFFF are reserved for use by UEFI OS loaders that are provided by operating system vendors.

Size

The number of bytes to allocate from the pool.

Buffer

A pointer to a pointer to the allocated buffer if the call succeeds; undefined otherwise.

Note: UEFI applications and UEFI drivers must not allocate memory of type **EfiReservedMemoryType**.

Description

The **AllocatePool()** function allocates a memory region of *Size* bytes from memory of type *PoolType* and returns the address of the allocated memory in the location referenced by *Buffer*. This function allocates pages from **EfiConventionalMemory** as needed to grow the requested pool type. All allocations are eight-byte aligned.

The allocated pool memory is returned to the available pool with the [EFI_BOOT_SERVICES.FreePool\(\)](#) function.

Status Codes Returned

EFI_SUCCESS	The requested number of bytes was allocated.
EFI_OUT_OF_RESOURCES	The pool requested could not be allocated.
EFI_INVALID_PARAMETER	<i>PoolType</i> is in the range EfiMaxMemoryType ..0x6FFFFFFF.
EFI_INVALID_PARAMETER	<i>PoolType</i> is EfiPersistentMemory .
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL.

EFI_BOOT_SERVICES.FreePool()

Summary

Returns pool memory to the system.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FREE_POOL) (
    IN VOID    *Buffer
);
```

Parameters

Buffer Pointer to the buffer to free.

Description

The **FreePool()** function returns the memory specified by *Buffer* to the system. On return, the memory's type is **EfiConventionalMemory**. The *Buffer* that is freed must have been allocated by **AllocatePool()**.

Status Codes Returned

EFI_SUCCESS	The memory was returned to the system.
EFI_INVALID_PARAMETER	<i>Buffer</i> was invalid.

6.3 Protocol Handler Services

In the abstract, a protocol consists of a 128-bit globally unique identifier (GUID) and a Protocol Interface structure. The structure contains the functions and instance data that are used to access a device. The functions that make up Protocol Handler Services allow applications to install a protocol on a handle, identify the handles that support a given protocol, determine whether a handle supports a given protocol, and so forth. See [Table 28](#).

Table 28. Protocol Interface Functions

Name	Type	Description
InstallProtocolInterface	Boot	Installs a protocol interface on a device handle.
UninstallProtocolInterface	Boot	Removes a protocol interface from a device handle.
ReinstallProtocolInterface	Boot	Reinstalls a protocol interface on a device handle.
RegisterProtocolNotify	Boot	Registers an event that is to be signaled whenever an interface is installed for a specified protocol.
LocateHandle	Boot	Returns an array of handles that support a specified protocol.

Name	Type	Description
HandleProtocol	Boot	Queries a handle to determine if it supports a specified protocol.
LocateDevicePath	Boot	Locates all devices on a device path that support a specified protocol and returns the handle to the device that is closest to the path.
OpenProtocol	Boot	Adds elements to the list of agents consuming a protocol interface.
CloseProtocol	Boot	Removes elements from the list of agents consuming a protocol interface.
OpenProtocolInformation	Boot	Retrieve the list of agents that are currently consuming a protocol interface.
ConnectController	Boot	Uses a set of precedence rules to find the best set of drivers to manage a controller.
DisconnectController	Boot	Informs a set of drivers to stop managing a controller.
ProtocolsPerHandle	Boot	Retrieves the list of protocols installed on a handle. The return buffer is automatically allocated.
LocateHandleBuffer	Boot	Retrieves the list of handles from the handle database that meet the search criteria. The return buffer is automatically allocated.
LocateProtocol	Boot	Finds the first handle in the handle database the supports the requested protocol.
InstallMultipleProtocolInterfaces	Boot	Installs one or more protocol interfaces onto a handle.
UninstallMultipleProtocolInterfaces	Boot	Uninstalls one or more protocol interfaces from a handle.

The Protocol Handler boot services have been modified to take advantage of the information that is now being tracked with the [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) and [EFI_BOOT_SERVICES.CloseProtocol\(\)](#) boot services. Since the usage of protocol interfaces is being tracked with these new boot services, it is now possible to safely uninstall and reinstall protocol interfaces that are being consumed by UEFI drivers.

As depicted in [Figure 20](#), the firmware is responsible for maintaining a “data base” that shows which protocols are attached to each device handle. (The figure depicts the “data base” as a linked list, but the choice of data structure is implementation-dependent.) The “data base” is built dynamically by calling the [EFI_BOOT_SERVICES.InstallProtocolInterface\(\)](#) function. Protocols can only be installed by UEFI drivers or the firmware itself. In the figure, a device handle (**EFI_HANDLE**) refers to a list of one or more registered protocol interfaces for that handle. The first handle in the system has four attached protocols, and the second handle has two attached protocols. Each attached protocol is represented as a GUID/Interface pointer pair. The GUID is the name of the protocol, and Interface points to a protocol instance. This data structure will typically contain a list of interface functions, and some amount of instance data.

Access to devices is initiated by calling the [EFI_BOOT_SERVICES.HandleProtocol\(\)](#) function, which determines whether a handle supports a given protocol. If it does, a pointer to the matching Protocol Interface structure is returned.

When a protocol is added to the system, it may either be added to an existing device handle or it may be added to create a new device handle. [Figure 20](#) shows that protocol handlers are listed for each device handle and that each protocol handler is logically a UEFI driver.

OM13155

Figure 20. Device Handle to Protocol Handler Mapping

The ability to add new protocol interfaces as new handles or to layer them on existing interfaces provides great flexibility. Layering makes it possible to add a new protocol that builds on a device’s basic protocols. An example of this might be to layer on a [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) support that would build on the handle’s underlying [EFI_SERIAL_IO_PROTOCOL](#).

The ability to add new handles can be used to generate new devices as they are found, or even to generate abstract devices. An example of this might be to add a multiplexing device that replaces *ConsoleOut* with a virtual device that multiplexes the [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) protocol onto multiple underlying device handles.

Driver Model Boot Services

Following is a detailed description of the new UEFI boot services that are required by the UEFI *Driver Model*. These boot services are being added to reduce the size and complexity of the bus drivers and device drivers. This, in turn, will reduce the amount of ROM space required by drivers that are programmed into ROMs on adapters or into system FLASH, and reduce the development and testing time required by driver writers.

These new services fall into two categories. The first group is used to track the usage of protocol interfaces by different agents in the system. Protocol interfaces are stored in a handle database. The handle database consists of a list of handles, and on each handle there is a list of one or more protocol interfaces. The boot services

[EFI_BOOT_SERVICES.InstallProtocolInterface\(\)](#),

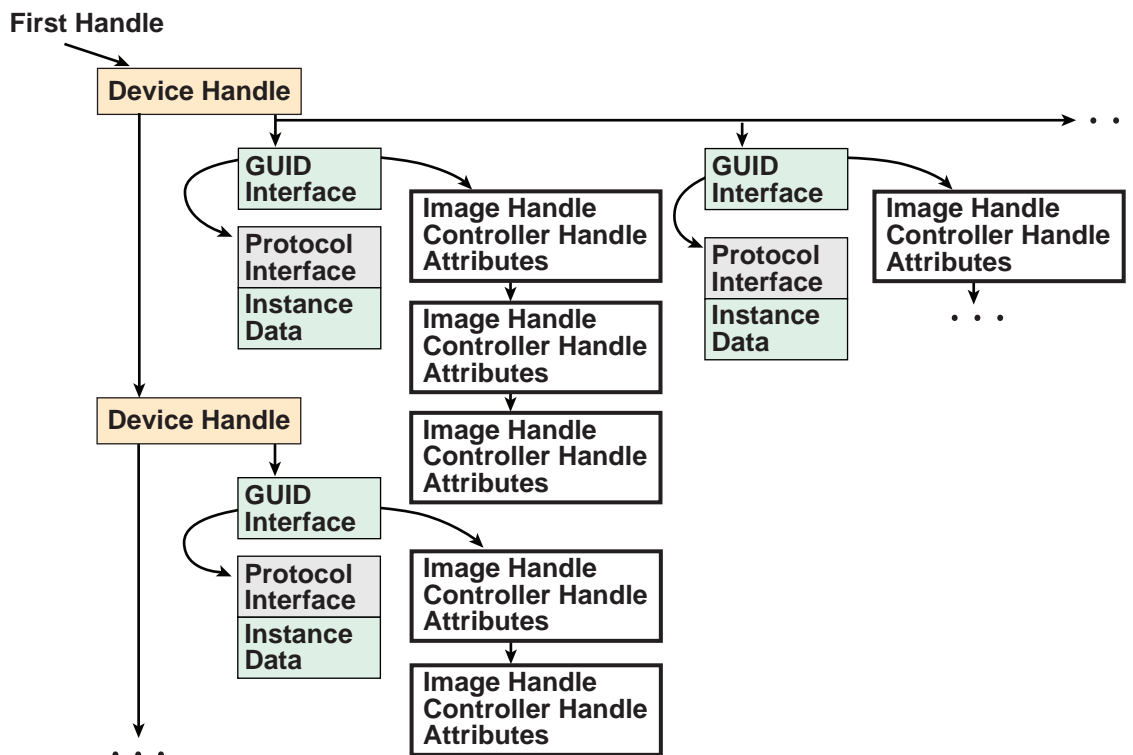

[EFI_BOOT_SERVICES.UninstallProtocolInterface\(\)](#), and

[EFI_BOOT_SERVICES.ReinstallProtocolInterface\(\)](#) are used to add, remove, and replace protocol interfaces in the handle database. The boot service

[EFI_BOOT_SERVICES.HandleProtocol\(\)](#) is used to look up a protocol interface in the handle database. However, agents that call **HandleProtocol()** are not tracked, so it is not safe to call **UninstallProtocolInterface()** or **ReinstallProtocolInterface()** because an agent may be using the protocol interface that is being removed or replaced.

The solution is to track the usage of protocol interfaces in the handle database itself. To accomplish this, each protocol interface includes a list of agents that are consuming the protocol interface.

[Figure 21](#) shows an example handle database with these new agent lists. An agent consists of an image handle, a controller handle, and some attributes. The image handle identifies the driver or application that is consuming the protocol interface. The controller handle identifies the controller that is consuming the protocol interface. Since a driver may manage more than one controller, the combination of a driver's image handle and a controller's controller handle uniquely identifies the agent that is consuming the protocol interface. The attributes show how the protocol interface is being used.

OM13156

Figure 21. Handle Database

In order to maintain these agent lists in the handle database, some new boot services are required. These are [EFI_BOOT_SERVICES.OpenProtocol\(\)](#), [EFI_BOOT_SERVICES.CloseProtocol\(\)](#), and [EFI_BOOT_SERVICES.OpenProtocolInformation\(\)](#). **OpenProtocol()** adds elements to the list of agents consuming a protocol interface. **CloseProtocol()** removes elements from the list of agents consuming a protocol interface, and [EFI_BOOT_SERVICES.OpenProtocolInformation\(\)](#) retrieves the entire list of agents that are currently using a protocol interface.

The second group of boot services is used to deterministically connect and disconnect drivers to controllers. The boot services in this group are [EFI_BOOT_SERVICES.ConnectController\(\)](#) and [EFI_BOOT_SERVICES.DisconnectController\(\)](#). These services take advantage of the new features of the handle database along with the new protocols described in this document to manage the drivers and controllers present in the system. **ConnectController()** uses a set of strict precedence rules to find the best set of drivers for a controller. This provides a deterministic matching of drivers to controllers with extensibility mechanisms for OEMs, IBVs, and IHVs. **DisconnectController()** allows drivers to be disconnected from controllers in a controlled manner, and by using the new features of the handle database it is possible to fail a disconnect request because a protocol interface cannot be released at the time of the disconnect request.

The third group of boot services is designed to help simplify the implementation of drivers, and produce drivers with smaller executable footprints. The [EFI BOOT SERVICES.LocateHandleBuffer\(\)](#) is a new version of [EFI BOOT SERVICES.LocateHandle\(\)](#) that allocates the required buffer for the caller. This eliminates two calls to `LocateHandle()` and a call to [EFI BOOT SERVICES.AllocatePool\(\)](#) from the caller's code. [EFI BOOT SERVICES.LocateProtocol\(\)](#) searches the handle database for the first protocol instance that matches the search criteria. The [EFI BOOT SERVICES.InstallMultipleProtocolInterfaces\(\)](#) and [EFI BOOT SERVICES.UninstallMultipleProtocolInterfaces\(\)](#) are very useful to driver writers. These boot services allow one or more protocol interfaces to be added or removed from a handle. In addition, `InstallMultipleProtocolInterfaces()` guarantees that a duplicate device path is never added to the handle database. This is very useful to bus drivers that can create one child handle at a time, because it guarantees that the bus driver will not inadvertently create two instances of the same child handle.

EFI_BOOT_SERVICES.InstallProtocolInterface()

Summary

Installs a protocol interface on a device handle. If the handle does not exist, it is created and added to the list of handles in the system. `InstallMultipleProtocolInterfaces()` performs more error checking than `InstallProtocolInterface()`, so it is recommended that `InstallMultipleProtocolInterfaces()` be used in place of `InstallProtocolInterface()`.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INSTALL_PROTOCOL_INTERFACE) (
    IN OUT EFI_HANDLE      *Handle,
    IN EFI_GUID            *Protocol,
    IN EFI_INTERFACE_TYPE  InterfaceType,
    IN VOID                *Interface
);
```

Parameters

<i>Handle</i>	A pointer to the EFI_HANDLE on which the interface is to be installed. If <i>*Handle</i> is NULL on input, a new handle is created and returned on output. If <i>*Handle</i> is not NULL on input, the protocol is added to the handle, and the handle is returned unmodified. The type EFI_HANDLE is defined in “Related Definitions.” If <i>*Handle</i> is not a valid handle, then EFI_INVALID_PARAMETER is returned.
<i>Protocol</i>	The numeric ID of the protocol interface. The type EFI_GUID is defined in “Related Definitions.” It is the caller’s responsibility to pass in a valid GUID. See “Wired For Management Baseline” for a description of valid GUID values.
<i>InterfaceType</i>	Indicates whether <i>Interface</i> is supplied in native form. This value indicates the original execution environment of the request. See “Related Definitions.”
<i>Interface</i>	A pointer to the protocol interface. The <i>Interface</i> must adhere to the structure defined by <i>Protocol</i> . NULL can be used if a structure is not associated with <i>Protocol</i> .

Related Definitions

```
/**
//*****
//EFI_HANDLE
//*****
typedef VOID *EFI_HANDLE;
```

```

//*****
//EFI_GUID
//*****
typedef struct {
    UINT32  Data1;
    UINT16  Data2;
    UINT16  Data3;
    UINT8   Data4[8];
} EFI_GUID;

//*****
//EFI_INTERFACE_TYPE
//*****
typedef enum {
    EFI_NATIVE_INTERFACE
} EFI_INTERFACE_TYPE;

```

Description

The **InstallProtocolInterface()** function installs a protocol interface (a GUID/Protocol Interface structure pair) on a device handle. The same GUID cannot be installed more than once onto the same handle. If installation of a duplicate GUID on a handle is attempted, an **EFI_INVALID_PARAMETER** will result.

Installing a protocol interface allows other components to locate the *Handle*, and the interfaces installed on it.

When a protocol interface is installed, the firmware calls all notification functions that have registered to wait for the installation of *Protocol*. For more information, see the [EFI_BOOT_SERVICES.RegisterProtocolNotify\(\)](#) function description.

Status Codes Returned

EFI_SUCCESS	The protocol interface was installed.
EFI_OUT_OF_RESOURCES	Space for a new handle could not be allocated.
EFI_INVALID_PARAMETER	<i>Handle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Protocol</i> is NULL .
EFI_INVALID_PARAMETER	<i>InterfaceType</i> is not EFI_NATIVE_INTERFACE .
EFI_INVALID_PARAMETER	<i>Protocol</i> is already installed on the handle specified by <i>Handle</i> .

EFI_BOOT_SERVICES.UninstallProtocolInterface()

Summary

Removes a protocol interface from a device handle. It is recommended that **UninstallMultipleProtocolInterfaces()** be used in place of **UninstallProtocolInterface()**.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_UNINSTALL_PROTOCOL_INTERFACE) (
    IN EFI_HANDLE    Handle,
    IN EFI_GUID      *Protocol,
    IN VOID           *Interface
);
```

Parameters

<i>Handle</i>	The handle on which the interface was installed. If <i>Handle</i> is not a valid handle, then EFI_INVALID_PARAMETER is returned. Type EFI_HANDLE is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>Protocol</i>	The numeric ID of the interface. It is the caller's responsibility to pass in a valid GUID. See "Wired For Management Baseline" for a description of valid GUID values. Type EFI_GUID is defined in the InstallProtocolInterface() function description.
<i>Interface</i>	A pointer to the interface. NULL can be used if a structure is not associated with <i>Protocol</i> .

Description

The **UninstallProtocolInterface()** function removes a protocol interface from the handle on which it was previously installed. The *Protocol* and *Interface* values define the protocol interface to remove from the handle.

The caller is responsible for ensuring that there are no references to a protocol interface that has been removed. In some cases, outstanding reference information is not available in the protocol, so the protocol, once added, cannot be removed. Examples include Console I/O, Block I/O, Disk I/O, and (in general) handles to device protocols.

If the last protocol interface is removed from a handle, the handle is freed and is no longer valid.

EFI 1.10 Extension

The extension to this service directly addresses the limitations described in the section above. There may be some drivers that are currently consuming the protocol interface that needs to be uninstalled, so it may be dangerous to just blindly remove a protocol interface from the system. Since the usage of protocol interfaces is now being tracked for components that use the

[EFI_BOOT_SERVICES.OpenProtocol\(\)](#) and [EFI_BOOT_SERVICES.CloseProtocol\(\)](#) boot services, a safe version of this function can be implemented. Before the protocol interface is removed, an attempt is made to force all the drivers that are consuming the protocol interface to stop consuming that protocol interface. This is done by calling the boot service [EFI_BOOT_SERVICES.DisconnectController\(\)](#) for the driver that currently have the protocol interface open with an attribute of **EFI_OPEN_PROTOCOL_BY_DRIVER** or **EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE**.

If the disconnect succeeds, then those agents will have called the boot service [EFI_BOOT_SERVICES.CloseProtocol\(\)](#) to release the protocol interface. Lastly, all of the agents that have the protocol interface open with an attribute of **EFI_OPEN_PROTOCOL_BY_HANDLE_PROTOCOL**, **EFI_OPEN_PROTOCOL_GET_PROTOCOL**, or **EFI_OPEN_PROTOCOL_TEST_PROTOCOL** are closed. If there are any agents remaining that still have the protocol interface open, the protocol interface is not removed from the handle and **EFI_ACCESS_DENIED** is returned. In addition, all of the drivers that were disconnected with the boot service **DisconnectController()** earlier, are reconnected with the boot service [EFI_BOOT_SERVICES.ConnectController\(\)](#). If there are no agents remaining that are consuming the protocol interface, then the protocol interface is removed from the handle as described above.

Status Codes Returned

EFI_SUCCESS	The interface was removed.
EFI_NOT_FOUND	The interface was not found.
EFI_ACCESS_DENIED	The interface was not removed because the interface is still being used by a driver.
EFI_INVALID_PARAMETER	<i>Handle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Protocol</i> is NULL .

EFI_BOOT_SERVICES.ReinstallProtocolInterface()

Summary

Reinstalls a protocol interface on a device handle.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_REINSTALL_PROTOCOL_INTERFACE) (
    IN EFI_HANDLE    Handle,
    IN EFI_GUID      *Protocol,
    IN VOID           *OldInterface,
    IN VOID           *NewInterface
);
```

Parameters

<i>Handle</i>	Handle on which the interface is to be reinstalled. If <i>Handle</i> is not a valid handle, then EFI_INVALID_PARAMETER is returned. Type EFI_HANDLE is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>Protocol</i>	The numeric ID of the interface. It is the caller's responsibility to pass in a valid GUID. See "Wired For Management Baseline" for a description of valid GUID values. Type EFI_GUID is defined in the InstallProtocolInterface() function description.
<i>OldInterface</i>	A pointer to the old interface. NULL can be used if a structure is not associated with <i>Protocol</i> .
<i>NewInterface</i>	A pointer to the new interface. NULL can be used if a structure is not associated with <i>Protocol</i> .

Description

The **ReinstallProtocolInterface()** function reinstalls a protocol interface on a device handle. The *OldInterface* for *Protocol* is replaced by the *NewInterface*. *NewInterface* may be the same as *OldInterface*. If it is, the registered protocol notifies occur for the handle without replacing the interface on the handle.

As with **InstallProtocolInterface()**, any process that has registered to wait for the installation of the interface is notified.

The caller is responsible for ensuring that there are no references to the *OldInterface* that is being removed.

EFI 1.10 Extension

The extension to this service directly addresses the limitations described in the section above. There may be some number of drivers currently consuming the protocol interface that is being reinstalled. In this case, it may be dangerous to replace a protocol interface in the system. It could result in an

unstable state, because a driver may attempt to use the old protocol interface after a new one has been reinstalled. Since the usage of protocol interfaces is now being tracked for components that use the [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) and [EFI_BOOT_SERVICES.CloseProtocol\(\)](#) boot services, a safe version of this function can be implemented.

When this function is called, a call is first made to the boot service [UninstallProtocolInterface\(\)](#). This will guarantee that all of the agents are currently consuming the protocol interface *OldInterface* will stop using *OldInterface*. If [UninstallProtocolInterface\(\)](#) returns **EFI_ACCESS_DENIED**, then this function returns **EFI_ACCESS_DENIED**, *OldInterface* remains on *Handle*, and the protocol notifies are not processed because *NewInterface* was never installed.

If [UninstallProtocolInterface\(\)](#) succeeds, then a call is made to the boot service [EFI_BOOT_SERVICES.InstallProtocolInterface\(\)](#) to put the *NewInterface* onto *Handle*.

Finally, the boot service [EFI_BOOT_SERVICES.ConnectController\(\)](#) is called so all agents that were forced to release *OldInterface* with [UninstallProtocolInterface\(\)](#) can now consume the protocol interface *NewInterface* that was installed with [InstallProtocolInterface\(\)](#). After *OldInterface* has been replaced with *NewInterface*, any process that has registered to wait for the installation of the interface is notified.

Status Codes Returned

EFI_SUCCESS	The protocol interface was reinstalled.
EFI_NOT_FOUND	The <i>OldInterface</i> on the handle was not found.
EFI_ACCESS_DENIED	The protocol interface could not be reinstalled, because <i>OldInterface</i> is still being used by a driver that will not release it.
EFI_INVALID_PARAMETER	<i>Handle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Protocol</i> is NULL .

EFI_BOOT_SERVICES.RegisterProtocolNotify()

Summary

Creates an event that is to be signaled whenever an interface is installed for a specified protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_REGISTER_PROTOCOL_NOTIFY) (
    IN EFI_GUID    *Protocol,
    IN EFI_EVENT   Event,
    OUT VOID       **Registration
);
```

Parameters

<i>Protocol</i>	The numeric ID of the protocol for which the event is to be registered. Type EFI_GUID is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>Event</i>	Event that is to be signaled whenever a protocol interface is registered for <i>Protocol</i> . The type EFI_EVENT is defined in the CreateEvent() function description. The same EFI_EVENT may be used for multiple protocol notify registrations.
<i>Registration</i>	A pointer to a memory location to receive the registration value. This value must be saved and used by the notification function of <i>Event</i> to retrieve the list of handles that have added a protocol interface of type <i>Protocol</i> .

Description

The [RegisterProtocolNotify\(\)](#) function creates an event that is to be signaled whenever a protocol interface is installed for *Protocol* by [InstallProtocolInterface\(\)](#) or [EFI_BOOT_SERVICES.ReinstallProtocolInterface\(\)](#).

Once **Event** has been signaled, the [EFI_BOOT_SERVICES.LocateHandle\(\)](#) function can be called to identify the newly installed, or reinstalled, handles that support *Protocol*. The **Registration** parameter in [EFI_BOOT_SERVICES.RegisterProtocolNotify\(\)](#) corresponds to the **SearchKey** parameter in [LocateHandle\(\)](#). Note that the same handle may be returned multiple times if the handle reinstalls the target protocol ID multiple times. This is typical for removable media devices, because when such a device reappears, it will reinstall the Block I/O protocol to indicate that the device needs to be checked again. In response, layered Disk I/O and Simple File System protocols may then reinstall their protocols to indicate that they can be re-checked, and so forth.

Events that have been registered for protocol interface notification can be unregistered by calling [CloseEvent\(\)](#).

Status Codes Returned

EFI_SUCCESS	The notification event has been registered.
EFI_OUT_OF_RESOURCES	Space for the notification event could not be allocated.
EFI_INVALID_PARAMETER	<i>Protocol</i> is NULL .
EFI_INVALID_PARAMETER	<i>Event</i> is NULL .
EFI_INVALID_PARAMETER	<i>Registration</i> is NULL .

EFI_BOOT_SERVICES.LocateHandle()

Summary

Returns an array of handles that support a specified protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_LOCATE_HANDLE) (
    IN EFI_LOCATE_SEARCH_TYPE    SearchType,
    IN EFI_GUID                  *Protocol OPTIONAL,
    IN VOID                      *SearchKey OPTIONAL,
    IN OUT UINTN                 *BufferSize,
    OUT EFI_HANDLE               *Buffer
);
```

Parameters

<i>SearchType</i>	Specifies which handle(s) are to be returned. Type EFI_LOCATE_SEARCH_TYPE is defined in “Related Definitions.”
<i>Protocol</i>	Specifies the protocol to search by. This parameter is only valid if <i>SearchType</i> is ByProtocol . Type EFI_GUID is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>SearchKey</i>	Specifies the search key. This parameter is ignored if <i>SearchType</i> is AllHandles or ByProtocol . If <i>SearchType</i> is ByRegisterNotify , the parameter must be the <i>Registration</i> value returned by function EFI_BOOT_SERVICES.RegisterProtocolNotify() .
<i>BufferSize</i>	On input, the size in bytes of <i>Buffer</i> . On output, the size in bytes of the array returned in <i>Buffer</i> (if the buffer was large enough) or the size, in bytes, of the buffer needed to obtain the array (if the buffer was not large enough).
<i>Buffer</i>	The buffer in which the array is returned. Type EFI_HANDLE is defined in the InstallProtocolInterface() function description.

Related Definitions

```
/**
//*****
// EFI_LOCATE_SEARCH_TYPE
//*****
typedef enum {
    AllHandles,
    ByRegisterNotify,
};
```

```

    ByProtocol
} EFI_LOCATE_SEARCH_TYPE;

```

- AllHandles** *Protocol* and *SearchKey* are ignored and the function returns an array of every handle in the system.
- ByRegisterNotify** *SearchKey* supplies the *Registration* value returned by [EFI_BOOT_SERVICES.RegisterProtocolNotify\(\)](#). The function returns the next handle that is new for the registration. Only one handle is returned at a time, starting with the first, and the caller must loop until no more handles are returned. *Protocol* is ignored for this search type.
- ByProtocol** All handles that support *Protocol* are returned. *SearchKey* is ignored for this search type.

Description

The **LocateHandle()** function returns an array of handles that match the *SearchType* request. If the input value of *BufferSize* is too small, the function returns **EFI_BUFFER_TOO_SMALL** and updates *BufferSize* to the size of the buffer needed to obtain the array.

Status Codes Returned

EFI_SUCCESS	The array of handles was returned.
EFI_NOT_FOUND	No handles match the search.
EFI_BUFFER_TOO_SMALL	The <i>BufferSize</i> is too small for the result. <i>BufferSize</i> has been updated with the size needed to complete the request.
EFI_INVALID_PARAMETER	<i>SearchType</i> is not a member of EFI_LOCATE_SEARCH_TYPE .
EFI_INVALID_PARAMETER	<i>SearchType</i> is ByRegisterNotify and <i>SearchKey</i> is NULL .
EFI_INVALID_PARAMETER	<i>SearchType</i> is ByProtocol and <i>Protocol</i> is NULL .
EFI_INVALID_PARAMETER	One or more matches are found and <i>BufferSize</i> is NULL .
EFI_INVALID_PARAMETER	<i>BufferSize</i> is large enough for the result and <i>Buffer</i> is NULL .

EFI_BOOT_SERVICES.HandleProtocol()

Summary

Queries a handle to determine if it supports a specified protocol.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_HANDLE_PROTOCOL) (
    IN EFI_HANDLE Handle,
    IN EFI_GUID *Protocol,
    OUT VOID **Interface
);
```

Parameters

<i>Handle</i>	The handle being queried. If <i>Handle</i> is NULL , then EFI_INVALID_PARAMETER is returned. Type EFI_HANDLE is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>Protocol</i>	The published unique identifier of the protocol. It is the caller's responsibility to pass in a valid GUID. See "Wired For Management Baseline" for a description of valid GUID values. Type EFI_GUID is defined in the InstallProtocolInterface() function description.
<i>Interface</i>	Supplies the address where a pointer to the corresponding Protocol Interface is returned. NULL will be returned in <i>Interface</i> if a structure is not associated with <i>Protocol</i> .

Description

The **HandleProtocol()** function queries **Handle** to determine if it supports *Protocol*. If it does, then on return *Interface* points to a pointer to the corresponding Protocol Interface. *Interface* can then be passed to any protocol service to identify the context of the request.

EFI 1.10 Extension

The **HandleProtocol()** function is still available for use by old EFI applications and drivers. However, all new applications and drivers should use [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) in place of **HandleProtocol()**. The following code fragment shows a possible implementation of **HandleProtocol()** using **OpenProtocol()**. The variable **EfiCoreImageHandle** is the image handle of the EFI core.

```
EFI_STATUS
HandleProtocol (
    IN EFI_HANDLE Handle,
    IN EFI_GUID *Protocol,
    OUT VOID **Interface
```

```

    )
  {
    return OpenProtocol (
      Handle,
      Protocol,
      Interface,
      EfiCoreImageHandle,
      NULL,
      EFI_OPEN_PROTOCOL_BY_HANDLE_PROTOCOL
    );
  }

```

Status Codes Returned

EFI_SUCCESS	The interface information for the specified protocol was returned.
EFI_UNSUPPORTED	The device does not support the specified protocol.
EFI_INVALID_PARAMETER	<i>Handle</i> is NULL ..
EFI_INVALID_PARAMETER	<i>Protocol</i> is NULL .
EFI_INVALID_PARAMETER	<i>Interface</i> is NULL .

EFI_BOOT_SERVICES.LocateDevicePath()

Summary

Locates the handle to a device on the device path that supports the specified protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_LOCATE_DEVICE_PATH) (
    IN EFI_GUID                *Protocol,
    IN OUT EFI_DEVICE_PATH_PROTOCOL **DevicePath,
    OUT EFI_HANDLE             *Device
);
```

Parameters

<i>Protocol</i>	The protocol to search for. Type EFI_GUID is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>DevicePath</i>	On input, a pointer to a pointer to the device path. On output, the device path pointer is modified to point to the remaining part of the device path—that is, when the function finds the closest handle, it splits the device path into two parts, stripping off the front part, and returning the remaining portion. EFI_DEVICE_PATH_PROTOCOL is defined in Section 9.2 .
<i>Device</i>	A pointer to the returned device handle. Type EFI_HANDLE is defined in the InstallProtocolInterface() function description.

Description

The **LocateDevicePath()** function locates all devices on *DevicePath* that support *Protocol* and returns the handle to the device that is closest to *DevicePath*. *DevicePath* is advanced over the device path nodes that were matched.

This function is useful for locating the proper instance of a protocol interface to use from a logical parent device driver. For example, a target device driver may issue the request with its own device path and locate the interfaces to perform I/O on its bus. It can also be used with a device path that contains a file path to strip off the file system portion of the device path, leaving the file path and handle to the file system driver needed to access the file.

If the handle for *DevicePath* supports the protocol (a direct match), the resulting device path is advanced to the device path terminator node. If *DevicePath* is a multi-instance device path, the function will operate on the first instance.

Status Codes Returned

EFI_SUCCESS	The resulting handle was returned.
EFI_NOT_FOUND	No handles matched the search.

EFI_INVALID_PARAMETER	<i>Protocol</i> is NULL
EFI_INVALID_PARAMETER	<i>DevicePath</i> is NULL .
EFI_INVALID_PARAMETER	A handle matched the search and <i>Device</i> is NULL .

EFI_BOOT_SERVICES.OpenProtocol()

Summary

Queries a handle to determine if it supports a specified protocol. If the protocol is supported by the handle, it opens the protocol on behalf of the calling agent. This is an extended version of the EFI boot service [EFI_BOOT_SERVICES.HandleProtocol\(\)](#).

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_OPEN_PROTOCOL) (
    IN  EFI_HANDLE          Handle,
    IN  EFI_GUID           *Protocol,
    OUT VOID               **Interface          OPTIONAL,
    IN  EFI_HANDLE          AgentHandle,
    IN  EFI_HANDLE          ControllerHandle,
    IN  UINT32              Attributes
);
```

Parameters

<i>Handle</i>	The handle for the protocol interface that is being opened.
<i>Protocol</i>	The published unique identifier of the protocol. It is the caller's responsibility to pass in a valid GUID. See "Wired For Management Baseline" for a description of valid GUID values.
<i>Interface</i>	Supplies the address where a pointer to the corresponding Protocol Interface is returned. NULL will be returned in <i>*Interface</i> if a structure is not associated with <i>Protocol</i> . This parameter is optional, and will be ignored if <i>Attributes</i> is EFI_OPEN_PROTOCOL_TEST_PROTOCOL .
<i>AgentHandle</i>	The handle of the agent that is opening the protocol interface specified by <i>Protocol</i> and <i>Interface</i> . For agents that follow the <i>UEFI Driver Model</i> , this parameter is the handle that contains the EFI_DRIVER_BINDING_PROTOCOL instance that is produced by the UEFI driver that is opening the protocol interface. For UEFI applications, this is the image handle of the UEFI application that is opening the protocol interface. For applications that use HandleProtocol() to open a protocol interface, this parameter is the image handle of the EFI firmware.
<i>ControllerHandle</i>	If the agent that is opening a protocol is a driver that follows the <i>UEFI Driver Model</i> , then this parameter is the controller handle that requires the protocol interface. If the agent does not follow the <i>UEFI Driver Model</i> , then this parameter is optional and may be NULL .
<i>Attributes</i>	The open mode of the protocol interface specified by <i>Handle</i> and <i>Protocol</i> . See "Related Definitions" for the list of legal attributes.

Description

This function opens a protocol interface on the handle specified by *Handle* for the protocol specified by *Protocol*. The first three parameters are the same as [EFI_BOOT_SERVICES.HandleProtocol\(\)](#). The only difference is that the agent that is opening a protocol interface is tracked in an EFI's internal handle database. The tracking is used by the *UEFI Driver Model*, and also used to determine if it is safe to uninstall or reinstall a protocol interface.

The agent that is opening the protocol interface is specified by *AgentHandle*, *ControllerHandle*, and *Attributes*. If the protocol interface can be opened, then *AgentHandle*, *ControllerHandle*, and *Attributes* are added to the list of agents that are consuming the protocol interface specified by *Handle* and *Protocol*. In addition, the protocol interface is returned in *Interface*, and **EFI_SUCCESS** is returned. If *Attributes* is **TEST_PROTOCOL**, then *Interface* is optional, and can be **NULL**.

There are a number of reasons that this function call can return an error. If an error is returned, then *AgentHandle*, *ControllerHandle*, and *Attributes* are not added to the list of agents consuming the protocol interface specified by *Handle* and *Protocol*, and *Interface* is returned unmodified. The following is the list of conditions that must be checked before this function can return **EFI_SUCCESS**.

If *Protocol* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *Interface* is **NULL** and *Attributes* is not **TEST_PROTOCOL**, then **EFI_INVALID_PARAMETER** is returned.

If *Handle* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *Handle* does not support *Protocol*, then **EFI_UNSUPPORTED** is returned.

If *Attributes* is not a legal value, then **EFI_INVALID_PARAMETER** is returned. The legal values are listed in “Related Definitions.”

If *Attributes* is **BY_CHILD_CONTROLLER**, **BY_DRIVER**, **EXCLUSIVE**, or **BY_DRIVER|EXCLUSIVE**, and *AgentHandle* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *Attributes* is **BY_CHILD_CONTROLLER**, **BY_DRIVER**, or **BY_DRIVER|EXCLUSIVE**, and *ControllerHandle* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *Attributes* is **BY_CHILD_CONTROLLER** and *Handle* is identical to *ControllerHandle*, then **EFI_INVALID_PARAMETER** is returned.

If *Attributes* is **BY_DRIVER**, **BY_DRIVER|EXCLUSIVE**, or **EXCLUSIVE**, and there are any items on the open list of the protocol interface with an attribute of **EXCLUSIVE** or **BY_DRIVER|EXCLUSIVE**, then **EFI_ACCESS_DENIED** is returned.

If *Attributes* is **BY_DRIVER**, and there are any items on the open list of the protocol interface with an attribute of **BY_DRIVER**, and *AgentHandle* is the same agent handle in the open list item, then **EFI_ALREADY_STARTED** is returned.

If *Attributes* is **BY_DRIVER**, and there are any items on the open list of the protocol interface with an attribute of **BY_DRIVER**, and *AgentHandle* is different than the agent handle in the open list item, then **EFI_ACCESS_DENIED** is returned.

If *Attributes* is **BY_DRIVER|EXCLUSIVE**, and there are any items on the open list of the protocol interface with an attribute of **BY_DRIVER|EXCLUSIVE**, and *AgentHandle* is the same agent handle in the open list item, then **EFI_ALREADY_STARTED** is returned.

If *Attributes* is **BY_DRIVER|EXCLUSIVE**, and there are any items on the open list of the protocol interface with an attribute of **BY_DRIVER|EXCLUSIVE**, and *AgentHandle* is different than the agent handle in the open list item, then **EFI_ACCESS_DENIED** is returned.

If *Attributes* is **BY_DRIVER|EXCLUSIVE** or **EXCLUSIVE**, and there is an item on the open list of the protocol interface with an attribute of **BY_DRIVER**, then the boot service [EFI_BOOT_SERVICES.DisconnectController\(\)](#) is called for the driver on the open list. If there is an item in the open list of the protocol interface with an attribute of **BY_DRIVER** remaining after the **DisconnectController()** call has been made, **EFI_ACCESS_DENIED** is returned.

Related Definitions

```
#define EFI_OPEN_PROTOCOL_BY_HANDLE_PROTOCOL    0x00000001
#define EFI_OPEN_PROTOCOL_GET_PROTOCOL         0x00000002
#define EFI_OPEN_PROTOCOL_TEST_PROTOCOL        0x00000004
#define EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER  0x00000008
#define EFI_OPEN_PROTOCOL_BY_DRIVER           0x00000010
#define EFI_OPEN_PROTOCOL_EXCLUSIVE           0x00000020
```

The following is the list of legal values for the *Attributes* parameter, and how each value is used.

- BY_HANDLE_PROTOCOL** Used in the implementation of [EFI_BOOT_SERVICES.HandleProtocol\(\)](#). Since [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) performs the same function as **HandleProtocol()** with additional functionality, **HandleProtocol()** can simply call **OpenProtocol()** with this *Attributes* value.
- GET_PROTOCOL** Used by a driver to get a protocol interface from a handle. Care must be taken when using this open mode because the driver that opens a protocol interface in this manner will not be informed if the protocol interface is uninstalled or reinstalled. The caller is also not required to close the protocol interface with [EFI_BOOT_SERVICES.CloseProtocol\(\)](#).
- TEST_PROTOCOL** Used by a driver to test for the existence of a protocol interface on a handle. *Interface* is optional for this attribute value, so it is ignored, and the caller should only use the return status code. The caller is also not required to close the protocol interface with **CloseProtocol()**.
- BY_CHILD_CONTROLLER** Used by bus drivers to show that a protocol interface is being used by one of the child controllers of a bus. This information is used by the boot service [EFI_BOOT_SERVICES.ConnectController\(\)](#) to recursively connect all child controllers and by the boot service

[EFI_BOOT_SERVICES.DisconnectController\(\)](#) to get the list of child controllers that a bus driver created.

BY_DRIVER

Used by a driver to gain access to a protocol interface. When this mode is used, the driver's [Stop\(\)](#) function will be called by [EFI_BOOT_SERVICES.DisconnectController\(\)](#) if the protocol interface is reinstalled or uninstalled. Once a protocol interface is opened by a driver with this attribute, no other drivers will be allowed to open the same protocol interface with the **BY_DRIVER** attribute.

BY_DRIVER|EXCLUSIVE

Used by a driver to gain exclusive access to a protocol interface. If any other drivers have the protocol interface opened with an attribute of **BY_DRIVER**, then an attempt will be made to remove them with [DisconnectController\(\)](#).

EXCLUSIVE

Used by applications to gain exclusive access to a protocol interface. If any drivers have the protocol interface opened with an attribute of **BY_DRIVER**, then an attempt will be made to remove them by calling the driver's **Stop()** function.

Status Codes Returned

EFI_SUCCESS	An item was added to the open list for the protocol interface, and the protocol interface was returned in <i>Interface</i> .
EFI_INVALID_PARAMETER	<i>Protocol</i> is NULL .
EFI_INVALID_PARAMETER	<i>Interface</i> is NULL , and <i>Attributes</i> is not TEST_PROTOCOL .
EFI_INVALID_PARAMETER	<i>Handle</i> is NULL ..
EFI_UNSUPPORTED	<i>Handle</i> does not support <i>Protocol</i> .
EFI_INVALID_PARAMETER	<i>Attributes</i> is not a legal value.
EFI_INVALID_PARAMETER	<i>Attributes</i> is BY_CHILD_CONTROLLER and <i>AgentHandle</i> is NULL ..
EFI_INVALID_PARAMETER	<i>Attributes</i> is BY_DRIVER and <i>AgentHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Attributes</i> is BY_DRIVER EXCLUSIVE and <i>AgentHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Attributes</i> is EXCLUSIVE and <i>AgentHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Attributes</i> is BY_CHILD_CONTROLLER and <i>ControllerHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Attributes</i> is BY_DRIVER and <i>ControllerHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Attributes</i> is BY_DRIVER EXCLUSIVE and <i>ControllerHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Attributes</i> is BY_CHILD_CONTROLLER and <i>Handle</i> is identical to <i>ControllerHandle</i> .

EFI_ACCESS_DENIED	<i>Attributes</i> is BY_DRIVER and there is an item on the open list with an attribute of BY_DRIVER EXCLUSIVE or EXCLUSIVE .
EFI_ACCESS_DENIED	<i>Attributes</i> is BY_DRIVER EXCLUSIVE and there is an item on the open list with an attribute of EXCLUSIVE .
EFI_ACCESS_DENIED	<i>Attributes</i> is EXCLUSIVE and there is an item on the open list with an attribute of BY_DRIVER EXCLUSIVE or EXCLUSIVE .
EFI_ALREADY_STARTED	<i>Attributes</i> is BY_DRIVER and there is an item on the open list with an attribute of BY_DRIVER whose agent handle is the same as <i>AgentHandle</i> .
EFI_ACCESS_DENIED	<i>Attributes</i> is BY_DRIVER and there is an item on the open list with an attribute of BY_DRIVER whose agent handle is different than <i>AgentHandle</i> .
EFI_ALREADY_STARTED	<i>Attributes</i> is BY_DRIVER EXCLUSIVE and there is an item on the open list with an attribute of BY_DRIVER EXCLUSIVE whose agent handle is the same as <i>AgentHandle</i> .
EFI_ACCESS_DENIED	<i>Attributes</i> is BY_DRIVER EXCLUSIVE and there is an item on the open list with an attribute of BY_DRIVER EXCLUSIVE whose agent handle is different than <i>AgentHandle</i> .
EFI_ACCESS_DENIED	<i>Attributes</i> is BY_DRIVER EXCLUSIVE or EXCLUSIVE and there are items in the open list with an attribute of BY_DRIVER that could not be removed when <u>EFI_BOOT_SERVICES.DisconnectController()</u> was called for that open item.

```

EFI_BOOT_SERVICES.CloseProtocol()

Summary

Closes a protocol on a handle that was opened using [EFI_BOOT_SERVICES.OpenProtocol\(\)](#).

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CLOSE_PROTOCOL) (
    IN EFI_HANDLE           Handle,
    IN EFI_GUID             *Protocol,
    IN EFI_HANDLE           AgentHandle,
    IN EFI_HANDLE           ControllerHandle
);
```

Parameters

<i>Handle</i>	The handle for the protocol interface that was previously opened with OpenProtocol() , and is now being closed.
<i>Protocol</i>	The published unique identifier of the protocol. It is the caller's responsibility to pass in a valid GUID. See "Wired For Management Baseline" for a description of valid GUID values.
<i>AgentHandle</i>	The handle of the agent that is closing the protocol interface. For agents that follow the <i>UEFI Driver Model</i> , this parameter is the handle that contains the EFI_DRIVER_BINDING_PROTOCOL instance that is produced by the UEFI driver that is opening the protocol interface. For UEFI applications, this is the image handle of the UEFI application. For applications that used EFI_BOOT_SERVICES.HandleProtocol() to open the protocol interface, this will be the image handle of the EFI firmware.
<i>ControllerHandle</i>	If the agent that opened a protocol is a driver that follows the <i>UEFI Driver Model</i> , then this parameter is the controller handle that required the protocol interface. If the agent does not follow the <i>UEFI Driver Model</i> , then this parameter is optional and may be NULL .

Description

This function updates the handle database to show that the protocol instance specified by *Handle* and *Protocol* is no longer required by the agent and controller specified *AgentHandle* and *ControllerHandle*.

If *Handle* or *AgentHandle* is **NULL**, then [EFI_INVALID_PARAMETER](#) is returned. If *ControllerHandle* is not **NULL**, and *ControllerHandle* is **NULL**, then [EFI_INVALID_PARAMETER](#) is returned. If *Protocol* is **NULL**, then [EFI_INVALID_PARAMETER](#) is returned.

If the interface specified by *Protocol* is not supported by the handle specified by *Handle*, then **EFI_NOT_FOUND** is returned.

If the interface specified by *Protocol* is supported by the handle specified by *Handle*, then a check is made to see if the protocol instance specified by *Protocol* and *Handle* was opened by *AgentHandle* and *ControllerHandle* with [EFI_BOOT_SERVICES.OpenProtocol\(\)](#). If the protocol instance was not opened by *AgentHandle* and *ControllerHandle*, then **EFI_NOT_FOUND** is returned. If the protocol instance was opened by *AgentHandle* and *ControllerHandle*, then all of those references are removed from the handle database, and **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The protocol instance was closed.
EFI_INVALID_PARAMETER	<i>Handle</i> is NULL .
EFI_INVALID_PARAMETER	<i>AgentHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>ControllerHandle</i> is not NULL and <i>ControllerHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Protocol</i> is NULL .
EFI_NOT_FOUND	<i>Handle</i> does not support the protocol specified by <i>Protocol</i> .
EFI_NOT_FOUND	The protocol interface specified by <i>Handle</i> and <i>Protocol</i> is not currently open by <i>AgentHandle</i> and <i>ControllerHandle</i> .

Examples

```

EFI_BOOT_SERVICES      *gBS;
EFI_HANDLE              ImageHandle;
EFI_DRIVER_BINDING_PROTOCOL *This;
IN EFI_HANDLE           ControllerHandle,
extern EFI_GUID         gEfiXyzIoProtocol;
EFI_STATUS              Status;

//
// Close the XYZ I/O Protocol that was opened on behalf of ControllerHandle
//
Status = gBS->CloseProtocol (
    ControllerHandle,
    &gEfiXyzIoProtocol,
    This->DriverBindingHandle,
    ControllerHandle
);

//
// Close the XYZ I/O Protocol that was opened with BY_HANDLE_PROTOCOL
//
Status = gBS->CloseProtocol (
    ControllerHandle,
    &gEfiXyzIoProtocol,
    ImageHandle,
    NULL
);

```

EFI_BOOT_SERVICES.OpenProtocolInformation()

Summary

Retrieves the list of agents that currently have a protocol interface opened.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_OPEN_PROTOCOL_INFORMATION) (
    IN  EFI_HANDLE           Handle,
    IN  EFI_GUID            *Protocol,
    OUT EFI_OPEN_PROTOCOL_INFORMATION_ENTRY **EntryBuffer,
    OUT UINTN               *EntryCount
);
```

Parameters

<i>Handle</i>	The handle for the protocol interface that is being queried.
<i>Protocol</i>	The published unique identifier of the protocol. It is the caller's responsibility to pass in a valid GUID. See "Wired For Management Baseline" for a description of valid GUID values.
<i>EntryBuffer</i>	A pointer to a buffer of open protocol information in the form of EFI_OPEN_PROTOCOL_INFORMATION_ENTRY structures. See "Related Definitions" for the declaration of this type. The buffer is allocated by this service, and it is the caller's responsibility to free this buffer when the caller no longer requires the buffer's contents.
<i>EntryCount</i>	A pointer to the number of entries in <i>EntryBuffer</i> .

Related Definitions

```
typedef struct {
    EFI_HANDLE AgentHandle;
    EFI_HANDLE ControllerHandle;
    UINT32 Attributes;
    UINT32 OpenCount;
} EFI_OPEN_PROTOCOL_INFORMATION_ENTRY;
```

Description

This function allocates and returns a buffer of **EFI_OPEN_PROTOCOL_INFORMATION_ENTRY** structures. The buffer is returned in *EntryBuffer*, and the number of entries is returned in *EntryCount*.

If the interface specified by *Protocol* is not supported by the handle specified by *Handle*, then **EFI_NOT_FOUND** is returned.

If the interface specified by *Protocol* is supported by the handle specified by *Handle*, then *EntryBuffer* is allocated with the boot service [EFI_BOOT_SERVICES.AllocatePool\(\)](#),

and *EntryCount* is set to the number of entries in *EntryBuffer*. Each entry of *EntryBuffer* is filled in with the image handle, controller handle, and attributes that were passed to [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) when the protocol interface was opened. The field **OpenCount** shows the number of times that the protocol interface has been opened by the agent specified by **ImageHandle**, **ControllerHandle**, and **Attributes**. After the contents of *EntryBuffer* have been filled in, **EFI_SUCCESS** is returned. It is the caller's responsibility to call [EFI_BOOT_SERVICES.FreePool\(\)](#) on *EntryBuffer* when the caller no longer required the contents of *EntryBuffer*.

If there are not enough resources available to allocate *EntryBuffer*, then **EFI_OUT_OF_RESOURCES** is returned.

Status Codes Returned

EFI_SUCCESS	The open protocol information was returned in <i>EntryBuffer</i> , and the number of entries was returned <i>EntryCount</i> .
EFI_NOT_FOUND	<i>Handle</i> does not support the protocol specified by <i>Protocol</i> .
EFI_OUT_OF_RESOURCES	There are not enough resources available to allocate <i>EntryBuffer</i> .

Examples

See example in the [EFI_BOOT_SERVICES.LocateHandleBuffer\(\)](#) function description for an example on how **LocateHandleBuffer()**, [EFI_BOOT_SERVICES.ProtocolsPerHandle\(\)](#), **OpenProtocol()**, and [EFI_BOOT_SERVICES.OpenProtocolInformation\(\)](#) can be used to traverse the entire handle database.

EFI_BOOT_SERVICES.ConnectController()

Summary

Connects one or more drivers to a controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CONNECT_CONTROLLER) (
    IN  EFI_HANDLE           ControllerHandle,
    IN  EFI_HANDLE           *DriverImageHandle  OPTIONAL,
    IN  EFI_DEVICE_PATH_PROTOCOL *RemainingDevicePath  OPTIONAL,
    IN  BOOLEAN              Recursive
);
```

Parameters

- | | |
|----------------------------|--|
| <i>ControllerHandle</i> | The handle of the controller to which driver(s) are to be connected. |
| <i>DriverImageHandle</i> | A pointer to an ordered list handles that support the EFI_DRIVER_BINDING_PROTOCOL . The list is terminated by a NULL handle value. These handles are candidates for the Driver Binding Protocol(s) that will manage the controller specified by <i>ControllerHandle</i> . This is an optional parameter that may be NULL . This parameter is typically used to debug new drivers. |
| <i>RemainingDevicePath</i> | A pointer to the device path that specifies a child of the controller specified by <i>ControllerHandle</i> . This is an optional parameter that may be NULL . If it is NULL , then handles for all the children of <i>ControllerHandle</i> will be created. This parameter is passed unchanged to the Supported() and Start() services of the EFI_DRIVER_BINDING_PROTOCOL attached to <i>ControllerHandle</i> . |
| <i>Recursive</i> | If TRUE , then ConnectController() is called recursively until the entire tree of controllers below the controller specified by <i>ControllerHandle</i> have been created. If FALSE , then the tree of controllers is only expanded one level. |

Description

This function connects one or more drivers to the controller specified by *ControllerHandle*. If *ControllerHandle* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If there are no **EFI_DRIVER_BINDING_PROTOCOL** instances present in the system, then return **EFI_NOT_FOUND**. If there are not enough resources available to complete this function, then **EFI_OUT_OF_RESOURCES** is returned.

If the platform supports user authentication, as specified in [Section 34](#), the device path associated with *ControllerHandle* is checked against the connect permissions in the current user profile. If forbidden, then **EFI_SECURITY_VIOLATION** is returned. Then, before connecting any of the *DriverImageHandles*, the device path associated with the handle is checked against the connect permissions in the current user profile.

If *Recursive* is **FALSE**, then this function returns after all drivers have been connected to *ControllerHandle*. If *Recursive* is **TRUE**, then **ConnectController()** is called recursively on all of the child controllers of *ControllerHandle*. The child controllers can be identified by searching the handle database for all the controllers that have opened *ControllerHandle* with an attribute of **EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER**.

This functions uses five precedence rules when deciding the order that drivers are tested against controllers. These five rules from highest precedence to lowest precedence are as follows:

1. *Context Override* : *DriverImageHandle* is an ordered list of handles that support the **EFI_DRIVER_BINDING_PROTOCOL**. The highest priority image handle is the first element of the list, and the lowest priority image handle is the last element of the list. The list is terminated with a **NULL** image handle.
2. *Platform Driver Override* : If an **EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL** instance is present in the system, then the [GetDriver\(\)](#) service of this protocol is used to retrieve an ordered list of image handles for *ControllerHandle*. From this list, the image handles found in rule (1) above are removed. The first image handle returned from **GetDriver()** has the highest precedence, and the last image handle returned from **GetDriver()** has the lowest precedence. The ordered list is terminated when **GetDriver()** returns **EFI_NOT_FOUND**. It is legal for no image handles to be returned by **GetDriver()**. There can be at most a single instance in the system of the **EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL**. If there is more than one, then the system behavior is not deterministic.
3. *Driver Family Override Search* : The list of available driver image handles can be found by using the boot service [EFI_BOOT_SERVICES.LocateHandle\(\)](#) with a *SearchType* of *ByProtocol* for the GUID of the **EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL**. From this list, the image handles found in rules (1), and (2) above are removed. The remaining image handles are sorted from highest to lowest based on the value returned from the **GetVersion()** function of the **EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL** associated with each image handle.
4. *Bus Specific Driver Override* : If there is an instance of the **EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL** attached to *ControllerHandle*, then the [GetDriver\(\)](#) service of this protocol is used to retrieve an ordered list of image handle for *ControllerHandle*. From this list, the image handles found in rules (1), (2), and (3) above are removed. The first image handle returned from **GetDriver()** has the highest precedence, and the last image handle returned from **GetDriver()** has the lowest precedence. The ordered list is terminated when **GetDriver()** returns **EFI_NOT_FOUND**. It is legal for no image handles to be returned by **GetDriver()**.
5. *Driver Binding Search* : The list of available driver image handles can be found by using the boot service [EFI_BOOT_SERVICES.LocateHandle\(\)](#) with a *SearchType* of *ByProtocol* for the GUID of the **EFI_DRIVER_BINDING_PROTOCOL**. From this list, the image handles found in rules (1), (2), (3), and (4) above are removed. The remaining image

handles are sorted from highest to lowest based on the *Version* field of the **EFI_DRIVER_BINDING_PROTOCOL** instance associated with each image handle.

Each of the five groups of image handles listed above is tested against *ControllerHandle* in order by using the **EFI_DRIVER_BINDING_PROTOCOL** service **Supported()**.

RemainingDevicePath is passed into **Supported()** unmodified. The first image handle whose **Supported()** service returns **EFI_SUCCESS** is marked so the image handle will not be tried again during this call to **ConnectController()**. Then, the **Start()** service of the **EFI_DRIVER_BINDING_PROTOCOL** is called for *ControllerHandle*. Once again, *RemainingDevicePath* is passed in unmodified. Every time **Supported()** returns **EFI_SUCCESS**, the search for drivers restarts with the highest precedence image handle. This process is repeated until no image handles pass the **Supported()** check.

If at least one image handle returned **EFI_SUCCESS** from its **Start()** service, then **EFI_SUCCESS** is returned.

If no image handles returned **EFI_SUCCESS** from their **Start()** service then **EFI_NOT_FOUND** is returned unless *RemainingDevicePath* is not **NULL**, and *RemainingDevicePath* is an End Node. In this special case, **EFI_SUCCESS** is returned because it is not an error to fail to start a child controller that is specified by an End Device Path Node.

Status Codes Returned

EFI_SUCCESS	One or more drivers were connected to <i>ControllerHandle</i> .
EFI_SUCCESS	No drivers were connected to <i>ControllerHandle</i> , but <i>RemainingDevicePath</i> is not NULL , and it is an End Device Path Node.
EFI_INVALID_PARAMETER	<i>ControllerHandle</i> is NULL .
EFI_NOT_FOUND	There are no EFI_DRIVER_BINDING_PROTOCOL instances present in the system.
EFI_NOT_FOUND	No drivers were connected to <i>ControllerHandle</i> .
EFI_SECURITY_VIOLATION	The user has no permission to start UEFI device drivers on the device path associated with the <i>ControllerHandle</i> or specified by the <i>RemainingDevicePath</i> .

Examples

```
//
// Connect All Handles Example
// The following example recursively connects all controllers in a platform.
//

EFI_STATUS Status;
EFI_BOOT_SERVICES *gBS;
UINTN HandleCount;
EFI_HANDLE *HandleBuffer;
UINTN HandleIndex;

//
// Retrieve the list of all handles from the handle database
//
Status = gBS->LocateHandleBuffer (
```

```

        AllHandles,
        NULL,
        NULL,
        &HandleCount,
        &HandleBuffer
    );
if (!EFI_ERROR (Status)) {
    for (HandleIndex = 0; HandleIndex < HandleCount; HandleIndex++) {
        Status = gBS->ConnectController (
            HandleBuffer[HandleIndex],
            NULL,
            NULL,
            TRUE
        );
    }
    gBS->FreePool(HandleBuffer);
}

//
// Connect Device Path Example
// The following example walks the device path nodes of a device path, and
// connects only the drivers required to force a handle with that device path
// to be present in the handle database. This algorithm guarantees that
// only the minimum number of devices and drivers are initialized.
//

EFI_STATUS          Status;
EFI_DEVICE_PATH_PROTOCOL *DevicePath;
EFI_DEVICE_PATH_PROTOCOL *RemainingDevicePath;
EFI_HANDLE          Handle;

do {
    //
    // Find the handle that best matches the Device Path. If it is only a
    // partial match the remaining part of the device path is returned in
    // RemainingDevicePath.
    //
    RemainingDevicePath = DevicePath;
    Status = gBS->LocateDevicePath (
        &gEfiDevicePathProtocolGuid,
        &RemainingDevicePath,
        &Handle
    );
    if (EFI_ERROR(Status)) {
        return EFI_NOT_FOUND;
    }

    //
    // Connect all drivers that apply to Handle and RemainingDevicePath
    // If no drivers are connected Handle, then return EFI_NOT_FOUND
    // The Recursive flag is FALSE so only one level will be expanded.
    //
    Status = gBS->ConnectController (
        Handle,
        NULL,
        RemainingDevicePath,
        FALSE
    );
    if (EFI_ERROR(Status)) {
        return EFI_NOT_FOUND;
    }
}

```

```
//  
// Loop until RemainingDevicePath is an empty device path  
//  
} while (!IsDevicePathEnd (RemainingDevicePath));  
  
//  
// A handle with DevicePath exists in the handle database  
//  
return EFI_SUCCESS;
```

EFI_BOOT_SERVICES.DisconnectController()

Summary

Disconnects one or more drivers from a controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISCONNECT_CONTROLLER) (
    IN EFI_HANDLE  ControllerHandle,
    IN EFI_HANDLE  DriverImageHandle  OPTIONAL,
    IN EFI_HANDLE  ChildHandle        OPTIONAL
);
```

Parameters

- | | |
|--------------------------|--|
| <i>ControllerHandle</i> | The handle of the controller from which driver(s) are to be disconnected. |
| <i>DriverImageHandle</i> | The driver to disconnect from <i>ControllerHandle</i> . If <i>DriverImageHandle</i> is NULL , then all the drivers currently managing <i>ControllerHandle</i> are disconnected from <i>ControllerHandle</i> . |
| <i>ChildHandle</i> | The handle of the child to destroy. If <i>ChildHandle</i> is NULL , then all the children of <i>ControllerHandle</i> are destroyed before the drivers are disconnected from <i>ControllerHandle</i> . |

Description

This function disconnects one or more drivers from the controller specified by *ControllerHandle*. If *DriverImageHandle* is **NULL**, then all of the drivers currently managing *ControllerHandle* are disconnected from *ControllerHandle*. If *DriverImageHandle* is not **NULL**, then only the driver specified by *DriverImageHandle* is disconnected from *ControllerHandle*. If *ChildHandle* is **NULL**, then all of the children of *ControllerHandle* are destroyed before the drivers are disconnected from *ControllerHandle*. If *ChildHandle* is not **NULL**, then only the child controller specified by *ChildHandle* is destroyed. If *ChildHandle* is the only child of *ControllerHandle*, then the driver specified by *DriverImageHandle* will be disconnected from *ControllerHandle*. A driver is disconnected from a controller by calling the **Stop()** service of the **EFI_DRIVER_BINDING_PROTOCOL**. The **EFI_DRIVER_BINDING_PROTOCOL** is on the driver image handle, and the handle of the controller is passed into the **Stop()** service. The list of drivers managing a controller, and the list of children for a specific controller can be retrieved from the handle database with the boot service [EFI_BOOT_SERVICES.OpenProtocolInformation\(\)](#). If all the required drivers are disconnected from *ControllerHandle*, then **EFI_SUCCESS** is returned.

If *ControllerHandle* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If no drivers are managing *ControllerHandle*, then **EFI_SUCCESS** is returned. If *DriverImageHandle* is not **NULL**, and *DriverImageHandle* is **NULL**, then

EFI_INVALID_PARAMETER is returned. If *DriverImageHandle* is not **NULL**, and *DriverImageHandle* is not currently managing *ControllerHandle*, then **EFI_SUCCESS** is returned. If *ChildHandle* is not **NULL**, and *ChildHandle* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If there are not enough resources available to disconnect drivers from *ControllerHandle*, then **EFI_OUT_OF_RESOURCES** is returned.

Status Codes Returned

EFI_SUCCESS	One or more drivers were disconnected from the controller.
EFI_SUCCESS	On entry, no drivers are managing <i>ControllerHandle</i> .
EFI_SUCCESS	<i>DriverImageHandle</i> is not NULL , and on entry <i>DriverImageHandle</i> is not managing <i>ControllerHandle</i> .
EFI_INVALID_PARAMETER	<i>ControllerHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>DriverImageHandle</i> is not NULL , and it is not a valid EFI_HANDLE .
EFI_INVALID_PARAMETER	<i>ChildHandle</i> is not NULL , and it is not a valid EFI_HANDLE .
EFI_OUT_OF_RESOURCES	There are not enough resources available to disconnect any drivers from <i>ControllerHandle</i> .
EFI_DEVICE_ERROR	The controller could not be disconnected because of a device error.
EFI_INVALID_PARAMETER	<i>DriverImageHandle</i> does not support the EFI_DRIVER_BINDING_PROTOCOL .

Examples

```
//
// Disconnect All Handles Example
// The following example recursively disconnects all drivers from all
// controllers in a platform.
//

EFI_STATUS Status;
EFI_BOOT_SERVICES *gBS;
UINTN HandleCount;
EFI_HANDLE *HandleBuffer;
UINTN HandleIndex;

//
// Retrieve the list of all handles from the handle database
//
Status = gBS->LocateHandleBuffer (
    AllHandles,
    NULL,
    NULL,
    &HandleCount,
    &HandleBuffer
);
if (!EFI_ERROR (Status)) {
    for (HandleIndex = 0; HandleIndex < HandleCount; HandleIndex++) {
        Status = gBS->DisconnectController (
            HandleBuffer[HandleIndex],
            NULL,
```

Unified Extensible Firmware Interface Specification

```
        NULL
    );
}
gBS->FreePool(HandleBuffer);
```

EFI_BOOT_SERVICES.ProtocolsPerHandle()

Summary

Retrieves the list of protocol interface GUIDs that are installed on a handle in a buffer allocated from pool.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_PROTOCOLS_PER_HANDLE) (
    IN EFI_HANDLE Handle,
    OUT EFI_GUID ***ProtocolBuffer,
    OUT UINTN *ProtocolBufferCount
);
```

Parameters

<i>Handle</i>	The handle from which to retrieve the list of protocol interface GUIDs.
<i>ProtocolBuffer</i>	A pointer to the list of protocol interface GUID pointers that are installed on <i>Handle</i> . This buffer is allocated with a call to the Boot Service EFI_BOOT_SERVICES.AllocatePool() . It is the caller's responsibility to call the Boot Service EFI_BOOT_SERVICES.FreePool() when the caller no longer requires the contents of <i>ProtocolBuffer</i> .
<i>ProtocolBufferCount</i>	A pointer to the number of GUID pointers present in <i>ProtocolBuffer</i> .

Description

The **ProtocolsPerHandle()** function retrieves the list of protocol interface GUIDs that are installed on *Handle*. The list is returned in *ProtocolBuffer*, and the number of GUID pointers in *ProtocolBuffer* is returned in *ProtocolBufferCount*.

If *Handle* is **NULL** or *Handle* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *ProtocolBuffer* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *ProtocolBufferCount* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If there are not enough resources available to allocate *ProtocolBuffer*, then **EFI_OUT_OF_RESOURCES** is returned.

Status Codes Returned

EFI_SUCCESS	The list of protocol interface GUIDs installed on <i>Handle</i> was returned in <i>ProtocolBuffer</i> . The number of protocol interface GUIDs was returned in <i>ProtocolBufferCount</i> .
EFI_INVALID_PARAMETER	<i>Handle</i> is NULL .
EFI_INVALID_PARAMETER	<i>ProtocolBuffer</i> is NULL .
EFI_INVALID_PARAMETER	<i>ProtocolBufferCount</i> is NULL .
EFI_OUT_OF_RESOURCES	There is not enough pool memory to store the results.

Examples

See example in the [EFI_BOOT_SERVICES.LocateHandleBuffer\(\)](#) function description for an example on how **LocateHandleBuffer()**, [EFI_BOOT_SERVICES.ProtocolsPerHandle\(\)](#), [EFI_BOOT_SERVICES.OpenProtocol\(\)](#), and [EFI_BOOT_SERVICES.OpenProtocolInformation\(\)](#) can be used to traverse the entire handle database.

EFI_BOOT_SERVICES.LocateHandleBuffer()

Summary

Returns an array of handles that support the requested protocol in a buffer allocated from pool.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_LOCATE_HANDLE_BUFFER) (
    IN EFI_LOCATE_SEARCH_TYPE  SearchType,
    IN EFI_GUID                 *Protocol  OPTIONAL,
    IN VOID                     *SearchKey OPTIONAL,
    IN OUT UINTN                *NoHandles,
    OUT EFI_HANDLE              **Buffer
);
```

Parameters

<i>SearchType</i>	Specifies which handle(s) are to be returned.
<i>Protocol</i>	Provides the protocol to search by. This parameter is only valid for a <i>SearchType</i> of ByProtocol .
<i>SearchKey</i>	Supplies the search key depending on the <i>SearchType</i> .
<i>NoHandles</i>	The number of handles returned in <i>Buffer</i> .
<i>Buffer</i>	A pointer to the buffer to return the requested array of handles that support <i>Protocol</i> . This buffer is allocated with a call to the Boot Service EFI_BOOT_SERVICES.AllocatePool() . It is the caller's responsibility to call the Boot Service EFI_BOOT_SERVICES.FreePool() when the caller no longer requires the contents of <i>Buffer</i> .

Description

The **LocateHandleBuffer()** function returns one or more handles that match the *SearchType* request. *Buffer* is allocated from pool, and the number of entries in *Buffer* is returned in *NoHandles*. Each *SearchType* is described below:

AllHandles	<i>Protocol</i> and <i>SearchKey</i> are ignored and the function returns an array of every handle in the system.
ByRegisterNotify	<i>SearchKey</i> supplies the Registration returned by EFI_BOOT_SERVICES.RegisterProtocolNotify() . The function returns the next handle that is new for the Registration. Only one handle is returned at a time, and the caller must loop until no more handles are returned. <i>Protocol</i> is ignored for this search type.
ByProtocol	All handles that support <i>Protocol</i> are returned. <i>SearchKey</i> is ignored for this search type.

If *NoHandles* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *Buffer* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If there are no handles in the handle database that match the search criteria, then **EFI_NOT_FOUND** is returned.

If there are not enough resources available to allocate *Buffer*, then **EFI_OUT_OF_RESOURCES** is returned.

Status Codes Returned

EFI_SUCCESS	The array of handles was returned in <i>Buffer</i> , and the number of handles in <i>Buffer</i> was returned in <i>NoHandles</i> .
EFI_INVALID_PARAMETER	<i>NoHandles</i> is NULL
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL
EFI_NOT_FOUND	No handles match the search.
EFI_OUT_OF_RESOURCES	There is not enough pool memory to store the matching results.

Examples

```
//
// The following example traverses the entire handle database. First all of
// the handles in the handle database are retrieved by using
// LocateHandleBuffer(). Then it uses ProtocolsPerHandle() to retrieve the
// list of protocol GUIDs attached to each handle. Then it uses OpenProtocol()
// to get the protocol instance associated with each protocol GUID on the
// handle. Finally, it uses OpenProtocolInformation() to retrieve the list of
// agents that have opened the protocol on the handle. The caller of these
// functions must make sure that they free the return buffers with FreePool()
// when they are done.
//

EFI_STATUS Status;

                // ProtocolGuidArray[ProtocolIndex] is the protocol GUID
                // Instance is the protocol instance for the protocol
                // OpenInfo[OpenInfoIndex] is an agent that has opened a protocol
                //
            }
            if (OpenInfo != NULL) {
                gBS->FreePool (OpenInfo);
            }
        }
    }
    if (ProtocolGuidArray != NULL) {
        gBS->FreePool (ProtocolGuidArray);
    }
}
if (HandleBuffer != NULL) {
    gBS->FreePool (HandleBuffer);
}
}

```

EFI_BOOT_SERVICES.LocateProtocol()

Summary

Returns the first protocol instance that matches the given protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_LOCATE_PROTOCOL) (
    IN EFI_GUID *Protocol,
    IN VOID *Registration OPTIONAL,
    OUT VOID **Interface
);
```

Parameters

<i>Protocol</i>	Provides the protocol to search for.
<i>Registration</i>	Optional registration key returned from EFI_BOOT_SERVICES.RegisterProtocolNotify() . If <i>Registration</i> is NULL , then it is ignored.
<i>Interface</i>	On return, a pointer to the first interface that matches <i>Protocol</i> and <i>Registration</i> .

Description

The **LocateProtocol()** function finds the first device handle that support *Protocol*, and returns a pointer to the protocol interface from that handle in *Interface*. If no protocol instances are found, then *Interface* is set to **NULL**.

If *Interface* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *Registration* is **NULL**, and there are no handles in the handle database that support *Protocol*, then **EFI_NOT_FOUND** is returned.

If *Registration* is not **NULL**, and there are no new handles for *Registration*, then **EFI_NOT_FOUND** is returned.

Status Codes Returned

EFI_SUCCESS	A protocol instance matching <i>Protocol</i> was found and returned in <i>Interface</i> .
EFI_INVALID_PARAMETER	<i>Interface</i> is NULL .
EFI_NOT_FOUND	No protocol instances were found that match <i>Protocol</i> and <i>Registration</i> .

EFI_BOOT_SERVICES.InstallMultipleProtocolInterfaces()

Summary

Installs one or more protocol interfaces into the boot services environment.

Prototype

```
typedef
EFI_STATUS
EFIAPI *EFI_INSTALL_MULTIPLE_PROTOCOL_INTERFACES) (
    IN OUT EFI_HANDLE  *Handle,
    ...
);
```

Parameters

Handle The pointer to a handle to install the new protocol interfaces on, or a pointer to **NULL** if a new handle is to be allocated.

... A variable argument list containing pairs of protocol GUIDs and protocol interfaces.

Description

This function installs a set of protocol interfaces into the boot services environment. It removes arguments from the variable argument list in pairs. The first item is always a pointer to the protocol's GUID, and the second item is always a pointer to the protocol's interface. These pairs are used to call the boot service [EFI_BOOT_SERVICES.InstallProtocolInterface\(\)](#) to add a protocol interface to *Handle*. If *Handle* is **NULL** on entry, then a new handle will be allocated. The pairs of arguments are removed in order from the variable argument list until a **NULL** protocol GUID value is found. If any errors are generated while the protocol interfaces are being installed, then all the protocols installed prior to the error will be uninstalled with the boot service [EFI_BOOT_SERVICES.UninstallProtocolInterface\(\)](#) before the error is returned. The same GUID cannot be installed more than once onto the same handle.

It is illegal to have two handles in the handle database with identical device paths. This service performs a test to guarantee a duplicate device path is not inadvertently installed on two different handles. Before any protocol interfaces are installed onto *Handle*, the list of GUID/pointer pair parameters are searched to see if a Device Path Protocol instance is being installed. If a Device Path Protocol instance is going to be installed onto *Handle*, then a check is made to see if a handle is already present in the handle database with an identical Device Path Protocol instance. If an identical Device Path Protocol instance is already present in the handle database, then no protocols are installed onto *Handle*, and **EFI_ALREADY_STARTED** is returned.

Status Codes Returned

EFI_SUCCESS	All the protocol interfaces were installed.
EFI_ALREADY_STARTED	A Device Path Protocol instance was passed in that is already present in the handle database.

Unified Extensible Firmware Interface Specification

EFI_OUT_OF_RESOURCES	There was not enough memory in pool to install all the protocols.
EFI_INVALID_PARAMETER	Handle is NULL.
EFI_INVALID_PARAMETER	Protocol is already installed on the handle specified by Handle.

EFI_BOOT_SERVICES.UninstallMultipleProtocolInterfaces()

Summary

Removes one or more protocol interfaces into the boot services environment.

Prototype

```
typedef
EFI_STATUS
EFI_API *EFI_UNINSTALL_MULTIPLE_PROTOCOL_INTERFACES) (
    IN EFI_HANDLE Handle,
    ...
);
```

Parameters

Handle The handle to remove the protocol interfaces from.

...A variable argument list containing pairs of protocol GUIDs and protocol interfaces.

Description

This function removes a set of protocol interfaces from the boot services environment. It removes arguments from the variable argument list in pairs. The first item is always a pointer to the protocol's GUID, and the second item is always a pointer to the protocol's interface. These pairs are used to call the boot service [EFI_BOOT_SERVICES.UninstallProtocolInterface\(\)](#) to remove a protocol interface from *Handle*. The pairs of arguments are removed in order from the variable argument list until a **NULL** protocol GUID value is found. If all of the protocols are uninstalled from *Handle*, then **EFI_SUCCESS** is returned. If any errors are generated while the protocol interfaces are being uninstalled, then the protocols uninstalled prior to the error will be reinstalled with the boot service [EFI_BOOT_SERVICES.InstallProtocolInterface\(\)](#) and the status code **EFI_INVALID_PARAMETER** is returned.

Status Codes Returned

EFI_SUCCESS	All the protocol interfaces were removed.
EFI_INVALID_PARAMETER	One of the protocol interfaces was not previously installed on <i>Handle</i> .

6.4 Image Services

Three types of images can be loaded: UEFI applications written (see [Section 2.1.2](#)), UEFI boot services drivers (see [Section 2.1.4](#)), and EFI runtime drivers (see [Section 2.1.4](#)). A UEFI OS Loader (see [Section 2.1.3](#)) is a type of UEFI application. The most significant difference between these image types is the type of memory into which they are loaded by the firmware's loader. [Table 29](#) summarizes the differences between images.

Table 29. Image Type Differences Summary

	UEFI Application	UEFI Boot Service Driver	UEFI Runtime Driver
Description	<p>A transient application that is loaded during boot services time. UEFI applications are either unloaded when they complete (see Section 2.1.2), or they take responsibility for the continued operation of the system via ExitBootServices () (see Section 2.1.3).</p> <p>The UEFI applications are loaded in sequential order by the boot manager, but one UEFI application may dynamically load another.</p>	<p>A program that is loaded into boot services memory and stays resident until boot services terminate. See Section 2.1.4.</p>	<p>A program that is loaded into runtime services memory and stays resident during runtime. The memory required for a UEFI runtime services driver must be performed in a single memory allocation, and marked as EfiRuntimeServicesData. (Note that the memory only stays resident when booting an EFI-compatible operating system. Legacy operating systems will reuse the memory.) See Section 2.1.4.</p>
Loaded into memory type	EfiLoaderCode , EfiLoaderData	EfiBootServicesCode , EfiBootServicesData	EfiRuntimeServicesCode, EfiRuntimeServicesData
Default pool allocations from memory type	EfiLoaderData	EfiBootServicesData	EfiRuntimeServicesData
Exit behavior	When an application exits, firmware frees the memory used to hold its image.	When a UEFI boot service driver exits with an error code, firmware frees the memory used to hold its image. When a UEFI boot service driver's entry point completes with EFI_SUCCESS , the image is retained in memory.	When a UEFI runtime driver exits with an error code, firmware frees the memory used to hold its image. When a UEFI runtime services driver's entry point completes with EFI_SUCCESS , the image is retained in memory.
Notes	This type of image would not install any protocol interfaces or handles.	This type of image would typically use InstallProtocolInterface () .	A UEFI runtime driver can only allocate runtime memory during boot services time. Due to the complexity of performing a virtual relocation for a runtime image, this driver type is discouraged unless it is absolutely required.

Most UEFI images are loaded by the boot manager. When a UEFI application or UEFI driver is installed, the installation procedure registers itself with the boot manager for loading. However, in some cases a UEFI application or UEFI driver may want to programmatically load and start another UEFI image. This can be done with the [EFI_BOOT_SERVICES.LoadImage\(\)](#) and [EFI_BOOT_SERVICES.StartImage\(\)](#) interfaces. UEFI drivers may only load UEFI applications during the UEFI driver's initialization entry point. [Table 30](#) lists the functions that make up Image Services.

Table 30. Image Functions

Name	Type	Description
LoadImage	Boot	Loads an EFI image into memory.
StartImage	Boot	Transfers control to a loaded image's entry point.
UnloadImage	Boot	Unloads an image.
EFI_IMAGE_ENTRY_POINT	Boot	Prototype of an EFI Image's entry point.
Exit	Boot	Exits the image's entry point.
ExitBootServices	Boot	Terminates boot services.

The Image boot services have been modified to take advantage of the information that is now being tracked with the [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) and [EFI_BOOT_SERVICES.CloseProtocol\(\)](#) boot services. Since the usage of protocol interfaces is being tracked with these new boot services, it is now possible to automatically close protocol interfaces when a UEFI application or a UEFI driver is unloaded or exited.

EFI_BOOT_SERVICES.LoadImage()

Summary

Loads an EFI image into memory.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_IMAGE_LOAD) (
    IN BOOLEAN                BootPolicy,
    IN EFI_HANDLE             ParentImageHandle,
    IN EFI_DEVICE_PATH_PROTOCOL *DevicePath,
    IN VOID                   *SourceBuffer OPTIONAL,
    IN UINTN                  SourceSize,
    OUT EFI_HANDLE            *ImageHandle
);
```

Parameters

<i>BootPolicy</i>	If TRUE , indicates that the request originates from the boot manager, and that the boot manager is attempting to load <i>DevicePath</i> as a boot selection. Ignored if <i>SourceBuffer</i> is not NULL .
<i>ParentImageHandle</i>	The caller's image handle. Type EFI_HANDLE is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description. This field is used to initialize the <i>ParentHandle</i> field of the EFI_LOADED_IMAGE_PROTOCOL for the image that is being loaded.
<i>DevicePath</i>	The <i>DeviceHandle</i> specific file path from which the image is loaded. EFI_DEVICE_PATH_PROTOCOL is defined in Section 9.2 .
<i>SourceBuffer</i>	If not NULL , a pointer to the memory location containing a copy of the image to be loaded.
<i>SourceSize</i>	The size in bytes of <i>SourceBuffer</i> . Ignored if <i>SourceBuffer</i> is NULL .
<i>ImageHandle</i>	Pointer to the returned image handle that is created when the image is successfully loaded. Type EFI_HANDLE is defined in the InstallProtocolInterface() function description.

Related Definitions

```
#define EFI_HII_PACKAGE_LIST_PROTOCOL_GUID \
    { 0x6a1ee763, 0xd47a, 0x43b4, \
      { 0xaa, 0xbe, 0xef, 0x1d, 0xe2, 0xab, 0x56, 0xfc } }
```

```
typedef EFI_HII_PACKAGE_LIST_HEADER
*EFI_HII_PACKAGE_LIST_PROTOCOL;
```

Description

The **LoadImage ()** function loads an EFI image into memory and returns a handle to the image. The image is loaded in one of two ways.

- If *SourceBuffer* is not **NULL**, the function is a memory-to-memory load in which *SourceBuffer* points to the image to be loaded and *SourceSize* indicates the image's size in bytes. In this case, the caller has copied the image into *SourceBuffer* and can free the buffer once loading is complete.
- If *SourceBuffer* is **NULL**, the function is a file copy operation that uses the [EFI SIMPLE FILE SYSTEM PROTOCOL](#).

If there is no instance of [EFI SIMPLE FILE SYSTEM PROTOCOL](#) associated with file path, then this function will attempt to use [EFI_LOAD_FILE_PROTOCOL](#) (*BootPolicy* is **TRUE**) or [EFI_LOAD_FILE2_PROTOCOL](#), and then [EFI_LOAD_FILE_PROTOCOL](#) (*BootPolicy* is **FALSE**).

In all cases, this function will use the instance of these protocols associated with the handle that most closely matches *DevicePath* will be used. See the boot service description for more information on how the closest handle is located.

- In the case of [EFI_SIMPLE_FILE_SYSTEM_PROTOCOL](#), the path name from the File Path Media Device Path node(s) of *DevicePath* is used.
- In the case of [EFI_LOAD_FILE_PROTOCOL](#), the remaining device path nodes of *DevicePath* and the *BootPolicy* flag are passed to the [EFI_LOAD_FILE_PROTOCOL.LoadFile \(\)](#) function. The default image responsible for booting is loaded when *DevicePath* specifies only the device (and there are no further device nodes). For more information see the discussion of the [EFI_LOAD_FILE_PROTOCOL](#) in [Section 12.1](#).
- In the case of [EFI_LOAD_FILE2_PROTOCOL](#), the behavior is the same as above, except that it is only used if *BootOption* is **FALSE**. For more information, see the discussion of the [EFI_LOAD_FILE2_PROTOCOL](#).
- If the platform supports driver signing, as specified in [Section 30.4.2](#), and the image signature is not valid, then information about the image is recorded (see Image Execution Information Table in [Section 30.4.2](#)) and **EFI_SECURITY_VIOLATION** is returned.
- If the platform supports user authentication, as described in [Section 34](#), and loading of images on the specified *FilePath* is forbidden in the current user profile, then the information about the image is recorded (see Deferred Execution in [Section 34.1.5](#)) and **EFI_SECURITY_VIOLATION** is returned.

Once the image is loaded, firmware creates and returns an **EFI_HANDLE** that identifies the image and supports [EFI_LOADED_IMAGE_PROTOCOL](#) and the [EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL](#). The caller may fill in the image's "load options" data, or add additional protocol support to the handle before passing control to the newly loaded image by calling [EFI_BOOT_SERVICES.StartImage \(\)](#). Also, once the image is

loaded, the caller either starts it by calling **StartImage()** or unloads it by calling [EFI_BOOT_SERVICES.UnloadImage\(\)](#).

Once the image is loaded, **LoadImage()** installs **EFI_HII_PACKAGE_LIST_PROTOCOL** on the handle if the image contains a custom PE/COFF resource with the type 'HII'. The protocol's interface pointer points to the HII package list which is contained in the resource's data. The format of this is in [Section 31.3.1](#).

Status Codes Returned

EFI_SUCCESS	Image was loaded into memory correctly.
EFI_NOT_FOUND	Both <i>SourceBuffer</i> and <i>DevicePath</i> are NULL .
EFI_INVALID_PARAMETER	One of the parameters has an invalid value.
EFI_INVALID_PARAMETER	<i>ImageHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>ParentImageHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>ParentImageHandle</i> is NULL .
EFI_UNSUPPORTED	The image type is not supported.
EFI_OUT_OF_RESOURCES	Image was not loaded due to insufficient resources.
EFI_LOAD_ERROR	Image was not loaded because the image format was corrupt or not understood.
EFI_DEVICE_ERROR	Image was not loaded because the device returned a read error.
EFI_ACCESS_DENIED	Image was not loaded because the platform policy prohibits the image from being loaded. NULL is returned in <i>*ImageHandle</i> .
EFI_SECURITY_VIOLATION	Image was loaded and an <i>ImageHandle</i> was created with a valid EFI_LOADED_IMAGE_PROTOCOL . However, the current platform policy specifies that the image should not be started.

EFI_BOOT_SERVICES.StartImage()

Summary

Transfers control to a loaded image's entry point.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_IMAGE_START) (
    IN EFI_HANDLE          ImageHandle,
    OUT UINTN              *ExitDataSize,
    OUT CHAR16             **ExitData OPTIONAL
);
```

Parameters

<i>ImageHandle</i>	Handle of image to be started. Type EFI_HANDLE is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>ExitDataSize</i>	Pointer to the size, in bytes, of <i>ExitData</i> . If <i>ExitData</i> is NULL , then this parameter is ignored and the contents of <i>ExitDataSize</i> are not modified.
<i>ExitData</i>	Pointer to a pointer to a data buffer that includes a Null-terminated string, optionally followed by additional binary data. The string is a description that the caller may use to further indicate the reason for the image's exit.

Description

The **StartImage()** function transfers control to the entry point of an image that was loaded by [EFI_BOOT_SERVICES.LoadImage\(\)](#). The image may only be started one time.

Control returns from **StartImage()** when the loaded image's **EFI_IMAGE_ENTRY_POINT** returns or when the loaded image calls [EFI_BOOT_SERVICES.Exit\(\)](#). When that call is made, the *ExitData* buffer and *ExitDataSize* from **Exit()** are passed back through the *ExitData* buffer and *ExitDataSize* in this function. The caller of this function is responsible for returning the *ExitData* buffer to the pool by calling [EFI_BOOT_SERVICES.FreePool\(\)](#) when the buffer is no longer needed. Using **Exit()** is similar to returning from the image's **EFI_IMAGE_ENTRY_POINT** except that **Exit()** may also return additional *ExitData*. **Exit()** function description defines clean up procedure performed by the firmware once loaded image returns control.

EFI 1.10 Extension

To maintain compatibility with UEFI drivers that are written to the *EFI 1.02 Specification*, **StartImage()** must monitor the handle database before and after each image is started. If any handles are created or modified when an image is started, then [EFI_BOOT_SERVICES.ConnectController\(\)](#) must be called with the *Recursive*

parameter set to **TRUE** for each of the newly created or modified handles before **StartImage()** returns.

Status Codes Returned

EFI_INVALID_PARAMETER	<i>ImageHandle</i> is either an invalid image handle or the image has already been initialized with StartImage
Exit code from image	Exit code from image.
EFI_SECURITY_VIOLATION	The current platform policy specifies that the image should not be started.

EFI_BOOT_SERVICES.UnloadImage()

Summary

Unloads an image.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_IMAGE_UNLOAD) (
    IN EFI_HANDLE ImageHandle
);
```

Parameters

ImageHandle Handle that identifies the image to be unloaded.

Description

The **UnloadImage()** function unloads a previously loaded image.

There are three possible scenarios. If the image has not been started, the function unloads the image and returns **EFI_SUCCESS**.

If the image has been started and has an **Unload()** entry point, control is passed to that entry point. If the image's unload function returns **EFI_SUCCESS**, the image is unloaded; otherwise, the error returned by the image's unload function is returned to the caller. The image unload function is responsible for freeing all allocated memory and ensuring that there are no references to any freed memory, or to the image itself, before returning **EFI_SUCCESS**.

If the image has been started and does not have an **Unload()** entry point, the function returns **EFI_UNSUPPORTED**.

EFI 1.10 Extension

All of the protocols that were opened by *ImageHandle* using the boot service [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) are automatically closed with the boot service [EFI_BOOT_SERVICES.CloseProtocol\(\)](#). If all of the open protocols are closed, then **EFI_SUCCESS** is returned. If any call to **CloseProtocol()** fails, then the error code from **CloseProtocol()** is returned.

Status Codes Returned

EFI_SUCCESS	The image has been unloaded.
EFI_UNSUPPORTED	The image has been started, and does not support unload.
EFI_INVALID_PARAMETER	<i>ImageHandle</i> is not a valid image handle.
Exit code from Unload handler	Exit code from the image's unload function.

EFI_IMAGE_ENTRY_POINT

Summary

This is the declaration of an EFI image entry point. This can be the entry point to an application written to this specification, an EFI boot service driver, or an EFI runtime driver.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_IMAGE_ENTRY_POINT) (
    IN EFI_HANDLE                ImageHandle,
    IN EFI_SYSTEM_TABLE         *SystemTable
);
```

Parameters

<i>ImageHandle</i>	Handle that identifies the loaded image. Type EFI_HANDLE is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>SystemTable</i>	System Table for this image. Type EFI_SYSTEM_TABLE is defined in Section 4 .

Description

An image's entry point is of type **EFI_IMAGE_ENTRY_POINT**. After firmware loads an image into memory, control is passed to the image's entry point. The entry point is responsible for initializing the image. The image's *ImageHandle* is passed to the image. The *ImageHandle* provides the image with all the binding and data information it needs. This information is available through protocol interfaces. However, to access the protocol interfaces on *ImageHandle* requires access to boot services functions. Therefore, [EFI_BOOT_SERVICES.LoadImage\(\)](#) passes to the **EFI_IMAGE_ENTRY_POINT** a *SystemTable* that is inherited from the current scope of [LoadImage\(\)](#).

All image handles support the [EFI_LOADED_IMAGE_PROTOCOL](#) and the [EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL](#). These protocols can be used to obtain information about the loaded image's state—for example, the device from which the image was loaded and the image's load options. In addition, the *ImageHandle* may support other protocols provided by the parent image.

If the image supports dynamic unloading, it must supply an unload function in the **EFI_LOADED_IMAGE_PROTOCOL** structure before returning control from its entry point.

In general, an image returns control from its initialization entry point by calling [EFI_BOOT_SERVICES.Exit\(\)](#) or by returning control from its entry point. If the image returns control from its entry point, the firmware passes control to **Exit()** using the return code as the *ExitStatus* parameter to **Exit()**.

See **Exit()** below for entry point exit conditions.

EFI_BOOT_SERVICES.Exit()

Summary

Terminates a loaded EFI image and returns control to boot services.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EXIT) (
    IN EFI_HANDLE    ImageHandle,
    IN EFI_STATUS    ExitStatus,
    IN UINTN         ExitDataSize,
    IN CHAR16        *ExitData    OPTIONAL
);
```

Parameters

<i>ImageHandle</i>	Handle that identifies the image. This parameter is passed to the image on entry.
<i>ExitStatus</i>	The image's exit code.
<i>ExitDataSize</i>	The size, in bytes, of <i>ExitData</i> . Ignored if <i>ExitStatus</i> is EFI_SUCCESS .
<i>ExitData</i>	Pointer to a data buffer that includes a Null-terminated string, optionally followed by additional binary data. The string is a description that the caller may use to further indicate the reason for the image's exit. <i>ExitData</i> is only valid if <i>ExitStatus</i> is something other than EFI_SUCCESS . The <i>ExitData</i> buffer must be allocated by calling EFI_BOOT_SERVICES.AllocatePool() .

Description

The **Exit()** function terminates the image referenced by *ImageHandle* and returns control to boot services. This function may not be called if the image has already returned from its entry point ([EFI_IMAGE_ENTRY_POINT](#)) or if it has loaded any child images that have not exited (all child images must exit before this image can exit).

Using **Exit()** is similar to returning from the image's **EFI_IMAGE_ENTRY_POINT** except that **Exit()** may also return additional *ExitData*.

When an application exits a compliant system, firmware frees the memory used to hold the image. The firmware also frees its references to the *ImageHandle* and the handle itself. Before exiting, the application is responsible for freeing any resources it allocated. This includes memory (pages and/or pool), open file system handles, and so forth. The only exception to this rule is the *ExitData* buffer, which must be freed by the caller of [EFI_BOOT_SERVICES.StartImage\(\)](#). (If the buffer is needed, firmware must allocate it by calling [EFI_BOOT_SERVICES.AllocatePool\(\)](#) and must return a pointer to it to the caller of **StartImage()**.)

When an EFI boot service driver or runtime service driver exits, firmware frees the image only if the *ExitStatus* is an error code; otherwise the image stays resident in memory. The driver must not return an error code if it has installed any protocol handlers or other active callbacks into the system that have not (or cannot) be cleaned up. If the driver exits with an error code, it is responsible for freeing all resources before exiting. This includes any allocated memory (pages and/or pool), open file system handles, and so forth.

It is valid to call **Exit()** or **UnloadImage()** for an image that was loaded by [EFI_BOOT_SERVICES.LoadImage\(\)](#) before calling [EFI_BOOT_SERVICES.StartImage\(\)](#). This will free the image from memory without having started it.

EFI 1.10 Extension

If *ImageHandle* is a UEFI application, then all of the protocols that were opened by *ImageHandle* using the boot service [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) are automatically closed with the boot service [EFI_BOOT_SERVICES.CloseProtocol\(\)](#). If *ImageHandle* is a UEFI boot service driver or UEFI runtime service driver, and *ExitStatus* is an error code, then all of the protocols that were opened by *ImageHandle* using the boot service **OpenProtocol()** are automatically closed with the boot service **CloseProtocol()**. If *ImageHandle* is a UEFI boot service driver or UEFI runtime service driver, and *ExitStatus* is not an error code, then no protocols are automatically closed by this service.

Status Codes Returned

(Does not return.)	Image exit. Control is returned to the StartImage() call that invoked the image specified by <i>ImageHandle</i> .
EFI_SUCCESS	The image specified by <i>ImageHandle</i> was unloaded. This condition only occurs for images that have been loaded with LoadImage() but have not been started with StartImage() .
EFI_INVALID_PARAMETER	The image specified by <i>ImageHandle</i> has been loaded and started with LoadImage() and StartImage() , but the image is not the currently executing image.

EFI_BOOT_SERVICES.ExitBootServices()

Summary

Terminates all boot services.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EXIT_BOOT_SERVICES) (
    IN EFI_HANDLE ImageHandle,
    IN UINTN      MapKey
);
```

Parameters

<i>ImageHandle</i>	Handle that identifies the exiting image. Type EFI_HANDLE is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>MapKey</i>	Key to the latest memory map.

Description

The **ExitBootServices()** function is called by the currently executing UEFI OS loader image to terminate all boot services. On success, the UEFI OS loader becomes responsible for the continued operation of the system. All events of type **EVT_SIGNAL_EXIT_BOOT_SERVICES** must be signaled before **ExitBootServices()** returns **EFI_SUCCESS**. The events are only signaled once even if **ExitBootServices()** is called multiple times.

A UEFI OS loader must ensure that it has the system's current memory map at the time it calls **ExitBootServices()**. This is done by passing in the current memory map's *MapKey* value as returned by [EFI_BOOT_SERVICES.GetMemoryMap\(\)](#). Care must be taken to ensure that the memory map does not change between these two calls. It is suggested that **GetMemoryMap()** be called immediately before calling **ExitBootServices()**. If *MapKey* value is incorrect, **ExitBootServices()** returns **EFI_INVALID_PARAMETER** and **GetMemoryMap()** with **ExitBootServices()** must be called again. Firmware implementation may choose to do a partial shutdown of the boot services during the first call to **ExitBootServices()**. A UEFI OS loader should not make calls to any boot service function other than **GetMemoryMap()** after the first call to **ExitBootServices()**.

On success, the UEFI OS loader owns all available memory in the system. In addition, the UEFI OS loader can treat all memory in the map marked as **EfiBootServicesCode** and **EfiBootServicesData** as available free memory. No further calls to boot service functions or EFI device-handle-based protocols may be used, and the boot services watchdog timer is disabled. On success, several fields of the EFI System Table should be set to **NULL**. These include *ConsoleInHandle*, *ConIn*, *ConsoleOutHandle*, *ConOut*, *StandardErrorHandle*, *StdErr*, and *BootServicesTable*. In addition, since fields of the EFI System Table are being modified, the 32-bit CRC for the EFI System Table must be recomputed.

Firmware must ensure that timer event activity is stopped before any of the **EXIT_BOOT_SERVICES** handlers are called within UEFI drivers. UEFI Drivers must not rely on timer event functionality in order to accomplish ExitBootServices handling since timer events will be disabled.

Status Codes Returned

EFI_SUCCESS	Boot services have been terminated.
EFI_INVALID_PARAMETER	<i>MapKey</i> is incorrect.

6.5 Miscellaneous Boot Services

This section contains the remaining function definitions for boot services not defined elsewhere but which are required to complete the definition of the EFI environment. [Table 31](#) lists the Miscellaneous Boot Services Functions.

Table 31. Miscellaneous Boot Services Functions

Name	Type	Description
SetWatchDogTimer	Boot	Resets and sets a watchdog timer used during boot services time.
Stall	Boot	Stalls the processor.
CopyMem	Boot	Copies the contents of one buffer to another buffer.
SetMem	Boot	Fills a buffer with a specified value.
GetNextMonotonicCount	Boot	Returns a monotonically increasing count for the platform.
InstallConfigurationTable	Boot	Adds, updates, or removes a configuration table from the EFI System Table.
CalculateCrc32	Boot	Computes and returns a 32-bit CRC for a data buffer.

The [EFI_BOOT_SERVICES.CalculateCrc32\(\)](#) service was added because there are several places in EFI that 32-bit CRCs are used. These include the EFI System Table, the EFI Boot Services Table, the EFI Runtime Services Table, and the GUID Partition Table (GPT) structures. The **CalculateCrc32()** service allows new 32-bit CRCs to be computed, and existing 32-bit CRCs to be validated.

EFI_BOOT_SERVICES.SetWatchdogTimer()

Summary

Sets the system's watchdog timer.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SET_WATCHDOG_TIMER) ((
    IN UINTN                Timeout,
    IN UINT64               WatchdogCode,
    IN UINTN                DataSize,
    IN CHAR16               *WatchdogData    OPTIONAL
    );
```

Parameters

<i>Timeout</i>	The number of seconds to set the watchdog timer to. A value of zero disables the timer.
<i>WatchdogCode</i>	The numeric code to log on a watchdog timer timeout event. The firmware reserves codes 0x0000 to 0xFFFF. Loaders and operating systems may use other timeout codes.
<i>DataSize</i>	The size, in bytes, of <i>WatchdogData</i> .
<i>WatchdogData</i>	A data buffer that includes a Null-terminated string, optionally followed by additional binary data. The string is a description that the call may use to further indicate the reason to be logged with a watchdog event.

Description

The **SetWatchdogTimer()** function sets the system's watchdog timer.

If the watchdog timer expires, the event is logged by the firmware. The system may then either reset with the Runtime Service [ResetSystem\(\)](#), or perform a platform specific action that must eventually cause the platform to be reset. The watchdog timer is armed before the firmware's boot manager invokes an EFI boot option. The watchdog must be set to a period of 5 minutes. The EFI Image may reset or disable the watchdog timer as needed. If control is returned to the firmware's boot manager, the watchdog timer must be disabled.

The watchdog timer is only used during boot services. On successful completion of [EFI_BOOT_SERVICES.ExitBootServices\(\)](#) the watchdog timer is disabled.

The accuracy of the watchdog timer is +/- 1 second from the requested *Timeout*.

Status Codes Returned

EFI_SUCCESS	The timeout has been set.
EFI_INVALID_PARAMETER	The supplied <i>WatchdogCode</i> is invalid.
EFI_UNSUPPORTED	The system does not have a watchdog timer.

EFI_DEVICE_ERROR	The watch dog timer could not be programmed due to a hardware error.
------------------	--

EFI_BOOT_SERVICES.Stall()

Summary

Induces a fine-grained stall.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_STALL) (
    IN UINTN    Microseconds
)
```

Parameters

Microseconds The number of microseconds to stall execution.

Description

The **Stall()** function stalls execution on the processor for at least the requested number of microseconds. Execution of the processor is *not* yielded for the duration of the stall.

Status Codes Returned

EFI_SUCCESS	Execution was stalled at least the requested number of <i>Microseconds</i> .
-------------	--

EFI_BOOT_SERVICES.CopyMem()

Summary

The **CopyMem()** function copies the contents of one buffer to another buffer.

Prototype

```
typedef
VOID
(EFI_API *EFI_COPY_MEM) (
    IN VOID      *Destination,
    IN VOID      *Source,
    IN UINTN     Length
);
```

Parameters

<i>Destination</i>	Pointer to the destination buffer of the memory copy.
<i>Source</i>	Pointer to the source buffer of the memory copy.
<i>Length</i>	Number of bytes to copy from <i>Source</i> to <i>Destination</i> .

Description

The **CopyMem()** function copies *Length* bytes from the buffer *Source* to the buffer *Destination*.

The implementation of **CopyMem()** must be reentrant, and it must handle overlapping *Source* and *Destination* buffers. This means that the implementation of **CopyMem()** must choose the correct direction of the copy operation based on the type of overlap that exists between the *Source* and *Destination* buffers. If either the *Source* buffer or the *Destination* buffer crosses the top of the processor's address space, then the result of the copy operation is unpredictable.

The contents of the *Destination* buffer on exit from this service must match the contents of the *Source* buffer on entry to this service. Due to potential overlaps, the contents of the *Source* buffer may be modified by this service. The following rules can be used to guarantee the correct behavior:

1. If *Destination* and *Source* are identical, then no operation should be performed.
2. If $Destination > Source$ and $Destination < (Source + Length)$, then the data should be copied from the *Source* buffer to the *Destination* buffer starting from the end of the buffers and working toward the beginning of the buffers.
3. Otherwise, the data should be copied from the *Source* buffer to the *Destination* buffer starting from the beginning of the buffers and working toward the end of the buffers.

Status Codes Returned

None.

EFI_BOOT_SERVICES.SetMem()

Summary

The **SetMem()** function fills a buffer with a specified value.

Prototype

```
typedef
VOID
EFIAPI *EFI_SET_MEM) (
    IN VOID      *Buffer,
    IN UINTN     Size,
    IN UINT8     Value
);
```

Parameters

<i>Buffer</i>	Pointer to the buffer to fill.
<i>Size</i>	Number of bytes in <i>Buffer</i> to fill.
<i>Value</i>	Value to fill <i>Buffer</i> with.

Description

This function fills *Size* bytes of *Buffer* with *Value*. The implementation of **SetMem()** must be reentrant. If *Buffer* crosses the top of the processor's address space, the result of the **SetMem()** operation is unpredictable.

Status Codes Returned

None.

EFI_BOOT_SERVICES.GetNextMonotonicCount()

Summary

Returns a monotonically increasing count for the platform.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_GET_NEXT_MONOTONIC_COUNT) (
    OUT UINT64 *Count
);
```

Parameters

Count Pointer to returned value.

Description

The **GetNextMonotonicCount()** function returns a 64-bit value that is numerically larger than the last time the function was called.

The platform's monotonic counter is comprised of two parts: the high 32 bits and the low 32 bits. The low 32-bit value is volatile and is reset to zero on every system reset. It is increased by 1 on every call to **GetNextMonotonicCount()**. The high 32-bit value is nonvolatile and is increased by one on whenever the system resets or the low 32-bit counter overflows.

Status Codes Returned

EFI_SUCCESS	The next monotonic count was returned.
EFI_DEVICE_ERROR	The device is not functioning properly.
EFI_INVALID_PARAMETER	<i>Count</i> is NULL .

EFI_BOOT_SERVICES.InstallConfigurationTable()

Summary

Adds, updates, or removes a configuration table entry from the EFI System Table.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INSTALL_CONFIGURATION_TABLE) (
    IN EFI_GUID    *Guid,
    IN VOID        *Table
);
```

Parameters

Guid A pointer to the GUID for the entry to add, update, or remove.

Table A pointer to the configuration table for the entry to add, update, or remove. May be **NULL**.

Description

The **InstallConfigurationTable()** function is used to maintain the list of configuration tables that are stored in the EFI System Table. The list is stored as an array of (GUID, Pointer) pairs. The list must be allocated from pool memory with *PoolType* set to **EfiRuntimeServicesData**.

If *Guid* is **NULL**, **EFI_INVALID_PARAMETER** is returned. If *Guid* is valid, there are four possibilities:

- If *Guid* is not present in the System Table, and *Table* is not **NULL**, then the (*Guid*, *Table*) pair is added to the System Table. See Note below.
- If *Guid* is not present in the System Table, and *Table* is **NULL**, then **EFI_NOT_FOUND** is returned.
- If *Guid* is present in the System Table, and *Table* is not **NULL**, then the (*Guid*, *Table*) pair is updated with the new *Table* value.
- If *Guid* is present in the System Table, and *Table* is **NULL**, then the entry associated with *Guid* is removed from the System Table.

If an add, modify, or remove operation is completed, then **EFI_SUCCESS** is returned.

Note: *If there is not enough memory to perform an add operation, then **EFI_OUT_OF_RESOURCES** is returned.*

Status Codes Returned

EFI_SUCCESS	The (<i>Guid</i> , <i>Table</i>) pair was added, updated, or removed.
EFI_INVALID_PARAMETER	<i>Guid</i> is NULL .
EFI_NOT_FOUND	An attempt was made to delete a nonexistent entry.
EFI_OUT_OF_RESOURCES	There is not enough memory available to complete the operation.

EFI_BOOT_SERVICES.CalculateCrc32()

Summary

Computes and returns a 32-bit CRC for a data buffer.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_CALCULATE_CRC32)
  IN VOID      *Data,
  IN UINTN    DataSize,
  OUT UINT32   *Crc32
  );
```

Parameters

<i>Data</i>	A pointer to the buffer on which the 32-bit CRC is to be computed.
<i>DataSize</i>	The number of bytes in the buffer <i>Data</i> .
<i>Crc32</i>	The 32-bit CRC that was computed for the data buffer specified by <i>Data</i> and <i>DataSize</i> .

Description

This function computes the 32-bit CRC for the data buffer specified by *Data* and *DataSize*. If the 32-bit CRC is computed, then it is returned in *Crc32* and **EFI_SUCCESS** is returned.

If *Data* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *Crc32* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *DataSize* is 0, then **EFI_INVALID_PARAMETER** is returned.

Status Codes Returned

EFI_SUCCESS	The 32-bit CRC was computed for the data buffer and returned in <i>Crc32</i> .
EFI_INVALID_PARAMETER	<i>Data</i> is NULL .
EFI_INVALID_PARAMETER	<i>Crc32</i> is NULL .
EFI_INVALID_PARAMETER	<i>DataSize</i> is 0.

Services — Runtime Services

This section discusses the fundamental services that are present in a compliant system. The services are defined by interface functions that may be used by code running in the EFI environment. Such code may include protocols that manage device access or extend platform capability, as well as applications running in the preboot environment and EFI OS loaders.

Two types of services are described here:

- **Boot Services.** Functions that are available *before* a successful call to [EFI_BOOT_SERVICES.ExitBootServices\(\)](#). These functions are described in [Section 6](#).
- **Runtime Services.** Functions that are available *before and after* any call to [ExitBootServices\(\)](#). These functions are described in this section.

During boot, system resources are owned by the firmware and are controlled through boot services interface functions. These functions can be characterized as “global” or “handle-based.” The term “global” simply means that a function accesses system services and is available on all platforms (since all platforms support all system services). The term “handle-based” means that the function accesses a specific device or device functionality and may not be available on some platforms (since some devices are not available on some platforms). Protocols are created dynamically. This section discusses the “global” functions and runtime functions; subsequent sections discuss the “handle-based.”

UEFI applications (including UEFI OS loaders) must use boot services functions to access devices and allocate memory. On entry, an image is provided a pointer to a system table which contains the Boot Services dispatch table and the default handles for accessing the console. All boot services functionality is available until a UEFI OS loader loads enough of its own environment to take control of the system’s continued operation and then terminates boot services with a call to [ExitBootServices\(\)](#).

In principle, the [ExitBootServices\(\)](#) call is intended for use by the operating system to indicate that its loader is ready to assume control of the platform and all platform resource management. Thus boot services are available up to this point to assist the UEFI OS loader in preparing to boot the operating system. Once the UEFI OS loader takes control of the system and completes the operating system boot process, only runtime services may be called. Code other than the UEFI OS loader, however, may or may not choose to call [ExitBootServices\(\)](#). This choice may in part depend upon whether or not such code is designed to make continued use of EFI boot services or the boot services environment.

The rest of this section discusses individual functions. Runtime Services fall into these categories:

- Runtime Rules and Restrictions ([Section 7.1](#))
- Variable Services ([Section 7.2](#))
- Time Services ([Section 7.3](#))
- Virtual Memory Services ([Section 7.4](#))

- Miscellaneous Services ([Section 7.5](#))

7.1 Runtime Services Rules and Restrictions

All of the Runtime Services may be called with interrupts enabled if desired. The Runtime Service functions will internally disable interrupts when it is required to protect access to hardware resources. The interrupt enable control bit will be returned to its entry state after the access to the critical hardware resources is complete.

All callers of Runtime Services are restricted from calling the same or certain other Runtime Service functions prior to the completion and return of a previous Runtime Service call. These restrictions apply to:

- Runtime Services that have been interrupted
- Runtime Services that are active on another processor.

Callers are prohibited from using certain other services from another processor or on the same processor following an interrupt as specified in [Table 32](#). For this table ‘Busy’ is defined as the state when a Runtime Service has been entered and has not returned to the caller.

The consequence of a caller violating these restrictions is undefined except for certain special cases described below.

Table 32. Rules for Reentry Into Runtime Services

If previous call is busy in	Forbidden to call
Any	SetVirtualAddressMap()
ConvertPointer()	ConvertPointer()
SetVariable(), UpdateCapsule(), SetTime(), SetWakeupTime(), GetNextHighMonotonicCount()	ResetSystem()
GetVariable(), GetNextVariableName(), SetVariable(), QueryVariableInfo(), UpdateCapsule(), QueryCapsuleCapabilities(), GetNextHighMonotonicCount()	GetVariable(), GetNextVariableName(), SetVariable(), QueryVariableInfo(), UpdateCapsule(), QueryCapsuleCapabilities(), GetNextHighMonotonicCount()
GetTime(), SetTime(), GetWakeupTime(), SetWakeupTime()	GetTime(), SetTime(), GetWakeupTime(), SetWakeupTime()

7.1.1 Exception for Machine Check, INIT, and NMI

Certain asynchronous events (e.g., NMI on IA-32 and x64 systems, Machine Check and INIT on Itanium systems) can not be masked and may occur with any setting of interrupt

enabled. These events also may require OS level handler's involvement that may involve the invocation of some of the runtime services (see below).

If **SetVirtualAddressMap()** has been called, all calls to runtime services after Machine Check, INIT, or NMI, must be made using the virtual address map set by that call.

A Machine Check may have interrupted a runtime service (see below). If the OS determines that the Machine Check is recoverable, the OS level handler must follow the normal restrictions in [Table 32](#).

If the OS determines that the Machine Check is non-recoverable, the OS level handler may ignore the normal restrictions and may invoke the runtime services described in [Table 33](#) even in the case where a previous call was busy. The system firmware will honor the new runtime service call(s) and the operation of the previous interrupted call is not guaranteed. Any interrupted runtime functions will not be restarted.

The INIT and NMI events follow the same restrictions.

Note: *On Itanium systems, the OS Machine Check Handler must not call `ResetSystem()`. If a reset is required, the OS Machine Check Handler may request SAL to reset upon return to `SAL_CHECK`.*

The platform implementations are required to clear any runtime services in progress in order to enable the OS handler to invoke these runtime services even in the case where a previous call was busy. In this case, the proper operation of the original interrupted call is not guaranteed.

Table 33. Functions that may be called after Machine Check ,INIT and NMI

Function	Called after Machine Check, INIT and NMI
GetTime()	Yes, even if previously busy
GetVariable()	Yes, even if previously busy
GetNextVariableName()	Yes, even if previously busy
QueryVariableInfo()	Yes, even if previously busy
SetVariable()	Yes, even if previously busy
UpdateCapsule()	Yes, even if previously busy
QueryCapsuleCapabilities()	Yes, even if previously busy
ResetSystem()	Yes, even if previously busy

7.2 Variable Services

Variables are defined as key/value pairs that consist of identifying information plus attributes (the key) and arbitrary data (the value). Variables are intended for use as a means to store data that is passed between the EFI environment implemented in the platform and EFI OS loaders and other applications that run in the EFI environment.

Although the implementation of variable storage is not defined in this specification, variables must be persistent in most cases. This implies that the EFI implementation on a platform must arrange it so that variables passed in for storage are retained and available for use each time the system boots, at least until they are explicitly deleted or overwritten. Provision of this type of nonvolatile storage may be very limited on some platforms, so variables should be used sparingly in cases where other means of communicating information cannot be used.

[Table 34](#) lists the variable services functions described in this section:

Table 34. Variable Services Functions

Name	Type	Description
GetVariable	Runtime	Returns the value of a variable.
GetNextVariableName	Runtime	Enumerates the current variable names.
SetVariable	Runtime	Sets the value of a variable.
QueryVariableInfo	Runtime	Returns information about the EFI variables

GetVariable()

Summary

Returns the value of a variable.

Prototype

```
typedef
EFI_STATUS
GetVariable (
    IN CHAR16          *VariableName,
    IN EFI_GUID       *VendorGuid,
    OUT UINT32        *Attributes OPTIONAL,
    IN OUT UINTN      *DataSize,
    OUT VOID          *Data OPTIONAL
);
```

Parameters

<i>VariableName</i>	A Null-terminated string that is the name of the vendor's variable.
<i>VendorGuid</i>	A unique identifier for the vendor. Type EFI_GUID is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>Attributes</i>	If not NULL , a pointer to the memory location to return the attributes bitmask for the variable. See "Related Definitions."
<i>DataSize</i>	On input, the size in bytes of the return <i>Data</i> buffer. On output the size of data returned in <i>Data</i> .
<i>Data</i>	The buffer to return the contents of the variable. May be NULL with a zero <i>DataSize</i> in order to determine the size buffer needed.

Related Definitions

```

//*****
// Variable Attributes
//*****
#define EFI_VARIABLE_NON_VOLATILE                0x00000001
#define EFI_VARIABLE_BOOTSERVICE_ACCESS        0x00000002
#define EFI_VARIABLE_RUNTIME_ACCESS             0x00000004
#define EFI_VARIABLE_HARDWARE_ERROR_RECORD      0x00000008 \
//This attribute is identified by the mnemonic 'HR' elsewhere
//in this specification.
#define EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS 0x00000010
#define EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS \
0x00000020
#define EFI_VARIABLE_APPEND_WRITE                0x00000040
    
```

Description

Each vendor may create and manage its own variables without the risk of name conflicts by using a unique *VendorGuid*. When a variable is set its *Attributes* are supplied to indicate how the data variable should be stored and maintained by the system. The attributes affect when the variable may be accessed and volatility of the data. Any attempts to access a variable that does not have the attribute set for runtime access will yield the **EFI_NOT_FOUND** error.

If the *Data* buffer is too small to hold the contents of the variable, the error **EFI_BUFFER_TOO_SMALL** is returned and *DataSize* is set to the required buffer size to obtain the data.

The **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** and the **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** attributes may both be set in the returned *Attributes* bitmask parameter of a **GetVariable()** call. The **EFI_VARIABLE_APPEND_WRITE** attribute will never be set in the returned *Attributes* bitmask parameter.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_NOT_FOUND	The variable was not found.
EFI_BUFFER_TOO_SMALL	The <i>DataSize</i> is too small for the result. <i>DataSize</i> has been updated with the size needed to complete the request.
EFI_INVALID_PARAMETER	<i>VariableName</i> is NULL .
EFI_INVALID_PARAMETER	<i>VendorGuid</i> is NULL .
EFI_INVALID_PARAMETER	<i>DataSize</i> is NULL .
EFI_INVALID_PARAMETER	The <i>DataSize</i> is not too small and <i>Data</i> is NULL .
EFI_DEVICE_ERROR	The variable could not be retrieved due to a hardware error.
EFI_SECURITY_VIOLATION	The variable could not be retrieved due to an authentication failure.

GetNextVariableName()

Summary

Enumerates the current variable names.

Prototype

```
typedef
EFI_STATUS
GetNextVariableName (
    IN OUT UINTN      *VariableNameSize,
    IN OUT CHAR16     *VariableName,
    IN OUT EFI_GUID   *VendorGuid
);
```

Parameters

<i>VariableNameSize</i>	The size of the <i>VariableName</i> buffer.
<i>VariableName</i>	On input, supplies the last <i>VariableName</i> that was returned by GetNextVariableName() . On output, returns the Null-terminated string of the current variable.
<i>VendorGuid</i>	On input, supplies the last <i>VendorGuid</i> that was returned by GetNextVariableName() . On output, returns the <i>VendorGuid</i> of the current variable. Type EFI_GUID is defined in the EFI BOOT SERVICES.InstallProtocolInterface() function description.

Description

GetNextVariableName() is called multiple times to retrieve the *VariableName* and *VendorGuid* of all variables currently available in the system. On each call to **GetNextVariableName()** the previous results are passed into the interface, and on output the interface returns the next variable name data. When the entire variable list has been returned, the error **EFI_NOT_FOUND** is returned.

Note that if **EFI_BUFFER_TOO_SMALL** is returned, the *VariableName* buffer was too small for the next variable. When such an error occurs, the *VariableNameSize* is updated to reflect the size of buffer needed. In all cases when calling **GetNextVariableName()** the *VariableNameSize* must not exceed the actual buffer size that was allocated for *VariableName*.

To start the search, a Null-terminated string is passed in *VariableName*; that is, *VariableName* is a pointer to a Null character. This is always done on the initial call to **GetNextVariableName()**. When *VariableName* is a pointer to a Null character, *VendorGuid* is ignored. **GetNextVariableName()** cannot be used as a filter to return variable names with a specific GUID. Instead, the entire list of variables must be retrieved, and the caller may act as a filter if it chooses. Calls to [SetVariable\(\)](#) between calls to **GetNextVariableName()** may produce unpredictable results. Passing in a *VariableName*

parameter that is neither a Null-terminated string nor a value that was returned on the previous call to [GetNextVariableName\(\)](#) may also produce unpredictable results.

Once [EFI_BOOT_SERVICES.ExitBootServices\(\)](#) is performed, variables that are only visible during boot services will no longer be returned. To obtain the data contents or attribute for a variable returned by [GetNextVariableName\(\)](#), the [GetVariable\(\)](#) interface is used.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_NOT_FOUND	The next variable was not found.
EFI_BUFFER_TOO_SMALL	The <i>VariableNameSize</i> is too small for the result. <i>VariableNameSize</i> has been updated with the size needed to complete the request.
EFI_INVALID_PARAMETER	<i>VariableNameSize</i> is NULL .
EFI_INVALID_PARAMETER	<i>VariableName</i> is NULL .
EFI_INVALID_PARAMETER	<i>VendorGuid</i> is NULL .
EFI_DEVICE_ERROR	The variable name could not be retrieved due to a hardware error.

SetVariable()

Summary

Sets the value of a variable.

Prototype

```
typedef
EFI_STATUS
SetVariable (
    IN CHAR16          *VariableName,
    IN EFI_GUID        *VendorGuid,
    IN UINT32          Attributes,
    IN UINTN           DataSize,
    IN VOID            *Data
);
```

Parameters

<i>VariableName</i>	A Null-terminated string that is the name of the vendor's variable. Each <i>VariableName</i> is unique for each <i>VendorGuid</i> . <i>VariableName</i> must contain 1 or more characters. If <i>VariableName</i> is an empty string, then EFI_INVALID_PARAMETER is returned.
<i>VendorGuid</i>	A unique identifier for the vendor. Type EFI_GUID is defined in the EFI_BOOT_SERVICES.InstallProtocolInterface() function description.
<i>Attributes</i>	Attributes bitmask to set for the variable. Refer to the GetVariable() function description.
<i>DataSize</i>	The size in bytes of the <i>Data</i> buffer. Unless the EFI_VARIABLE_APPEND_WRITE , EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS , or EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS attribute is set, a size of zero causes the variable to be deleted. When the EFI_VARIABLE_APPEND_WRITE attribute is set, then a SetVariable() call with a <i>DataSize</i> of zero will not cause any change to the variable value (the timestamp associated with the variable may be updated however, even if no new data value is provided; see the description of the EFI_VARIABLE_AUTHENTICATION_2 descriptor below). In this case the <i>DataSize</i> will not be zero since the EFI_VARIABLE_AUTHENTICATION_2 descriptor will be populated).
<i>Data</i>	The contents for the variable.

Related Definitions

```

//*****
// Variable Attributes
//*****

//
// EFI_VARIABLE_AUTHENTICATION descriptor
//
// A counter-based authentication method descriptor template
//
typedef struct {
    UINT64                MonotonicCount;
    WIN_CERTIFICATE_UEFI_GUID AuthInfo;
} EFI_VARIABLE_AUTHENTICATION;

```

MonotonicCount

Included in the signature of *AuthInfo*. Used to ensure freshness/no replay. Incremented during each "Write" access.

AuthInfo

Provides the authorization for the variable access. It is a signature across the variable data and the Monotonic Count value. Caller uses Private key that is associated with a public key that has been provisioned via the key exchange.

```

//
// EFI_VARIABLE_AUTHENTICATION_2 descriptor
//
// A time-based authentication method descriptor template
//
typedef struct {
    EFI_TIME                TimeStamp;
    WIN_CERTIFICATE_UEFI_GUID AuthInfo;
} EFI_VARIABLE_AUTHENTICATION_2;

```

TimeStamp

Time associated with the authentication descriptor. For the *TimeStamp* value, components *Pad1*, *Nanosecond*, *TimeZone*, *Daylight* and *Pad2* shall be set to 0. This means that the time shall always be expressed in GMT.

AuthInfo

Provides the authorization for the variable access. Only a *CertType* of **EFI_CERT_TYPE_PKCS7_GUID** is accepted.

Description

Variables are stored by the firmware and may maintain their values across power cycles. Each vendor may create and manage its own variables without the risk of name conflicts by using a unique *VendorGuid*.

Each variable has *Attributes* that define how the firmware stores and maintains the data value. If the **EFI_VARIABLE_NON_VOLATILE** attribute is *not* set, the firmware stores the variable in normal memory and it is not maintained across a power cycle. Such variables are used to pass information from one component to another. An example of this is the firmware's language code support variable. It is created at firmware initialization time for access by EFI components that may need the information, but does not need to be backed up to nonvolatile storage.

EFI_VARIABLE_NON_VOLATILE variables are stored in fixed hardware that has a limited storage capacity; sometimes a severely limited capacity. Software should only use a nonvolatile variable when absolutely necessary. In addition, if software uses a nonvolatile variable it should use a variable that is only accessible at boot services time if possible.

A variable must contain one or more bytes of *Data*. Unless the **EFI_VARIABLE_APPEND_WRITE**, **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS**, or **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute is set (see below), using **SetVariable()** with a *DataSize* of zero will cause the entire variable to be deleted. The space consumed by the deleted variable may not be available until the next power cycle.

The Attributes have the following usage rules:

- If a preexisting variable is rewritten with different attributes, **SetVariable()** shall not modify the variable and shall return **EFI_INVALID_PARAMETER**. The only exception to this is when the only attribute differing is **EFI_VARIABLE_APPEND_WRITE**. In such cases the call's successful outcome or not is determined by the actual value being written. There are two exceptions to this rule:
 - If a preexisting variable is rewritten with no access attributes specified, the variable will be deleted.
 - **EFI_VARIABLE_APPEND_WRITE** attribute presents a special case. It is acceptable to rewrite the variable with or without **EFI_VARIABLE_APPEND_WRITE** attribute.
- Setting a data variable with no access attributes causes it to be deleted.
- Unless the **EFI_VARIABLE_APPEND_WRITE**, **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS**, or **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute is set, setting a data variable with zero *DataSize* specified, causes it to be deleted.
- Runtime access to a data variable implies boot service access. Attributes that have **EFI_VARIABLE_RUNTIME_ACCESS** set must also have **EFI_VARIABLE_BOOTSERVICE_ACCESS** set. The caller is responsible for following this rule.
- Once [**EFI_BOOT_SERVICES.ExitBootServices\(\)**](#) is performed, data variables that did not have **EFI_VARIABLE_RUNTIME_ACCESS** set are no longer visible to [**GetVariable\(\)**](#).
- Once **ExitBootServices()** is performed, only variables that have **EFI_VARIABLE_RUNTIME_ACCESS** and **EFI_VARIABLE_NON_VOLATILE** set can be

set with **SetVariable()**. Variables that have runtime access but that are not nonvolatile are read-only data variables once **ExitBootServices()** is performed

- When the **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute is set in a **SetVariable()** call, the authentication shall use the **EFI_VARIABLE_AUTHENTICATION_2** descriptor.
- If both the **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** attribute and the **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute are set in a **SetVariable()** call, then the firmware must return **EFI_INVALID_PARAMETER**.
- If the **EFI_VARIABLE_APPEND_WRITE** attribute is set in a **SetVariable()** call, then any existing variable value shall be appended with the value of the *Data* parameter. If the firmware does not support the append operation, then the **SetVariable()** call shall return **EFI_INVALID_PARAMETER**.
- If the **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute is set in a **SetVariable()** call, and firmware does not support signature type of the certificate included in the **EFI_VARIABLE_AUTHENTICATION_2** descriptor, then the **SetVariable()** call shall return **EFI_INVALID_PARAMETER**. The list of signature types supported by the firmware is defined by the SignatureSupport variable. Signature type of the certificate is defined by its digest and encryption algorithms.
- If the **EFI_VARIABLE_HARDWARE_ERROR_RECORD** attribute is set, *VariableName* and *VendorGuid* must comply with the rules stated in [Section 7.2.3.2](#) and [Appendix P](#). Otherwise, the **SetVariable()** call shall return **EFI_INVALID_PARAMETER**.
- Globally Defined Variables defined in [Section 3.3](#) must be created with the attributes defined in the [Table 11](#). If a globally defined variable is created with the wrong attributes, the result is indeterminate and may vary between implementations.
- Secure Boot Policy Variable must be created with the **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute set, and the authentication shall use the **EFI_VARIABLE_AUTHENTICATION_2** descriptor. If the appropriate attribute bit is not set, then the firmware shall return **EFI_INVALID_PARAMETER**.

The only rules the firmware must implement when saving a nonvolatile variable is that it has actually been saved to nonvolatile storage before returning **EFI_SUCCESS**, and that a partial save is not performed. If power fails during a call to **SetVariable()** the variable may contain its previous value, or its new value. In addition there is no read, write, or delete security protection.

To delete a variable created with the **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** or the **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute, *SetVariable* must be used with attributes matching the existing variable and the *DataSize* set to the size of the *AuthInfo* descriptor. The *Data* buffer must contain an instance of the *AuthInfo* descriptor which will be validated according to the steps in the appropriate section above referring to updates of Authenticated variables. An attempt to delete a variable created with the **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** or **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute for which the prescribed *AuthInfo* validation fails or when called using *DataSize* of zero will fail with an **EFI_SECURITY_VIOLATION** status.

Status Codes Returned

EFI_SUCCESS	The firmware has successfully stored the variable and its data as defined by the Attributes.
EFI_INVALID_PARAMETER	An invalid combination of attribute bits, name, and GUID was supplied, or the <i>DataSize</i> exceeds the maximum allowed.
EFI_INVALID_PARAMETER	<i>VariableName</i> is an empty string.
EFI_OUT_OF_RESOURCES	Not enough storage is available to hold the variable and its data.
EFI_DEVICE_ERROR	The variable could not be saved due to a hardware failure.
EFI_WRITE_PROTECTED	The variable in question is read-only.
EFI_WRITE_PROTECTED	The variable in question cannot be deleted.
EFI_SECURITY_VIOLATION	The variable could not be written due to EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS or EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS being set, but the <i>AuthInfo</i> does NOT pass the validation check carried out by the firmware.
EFI_NOT_FOUND	The variable trying to be updated or deleted was not found.

7.2.1 Using the EFI_VARIABLE_AUTHENTICATION_2 descriptor (Recommended)

When the attribute **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** is set, then the Data buffer shall begin with an instance of a complete (and serialized) **EFI_VARIABLE_AUTHENTICATION_2** descriptor. The descriptor shall be followed by the new variable value and *DataSize* shall reflect the combined size of the descriptor and the new variable value. The authentication descriptor is not part of the variable data and is not returned by subsequent calls to **GetVariable()**.

A caller that invokes the **SetVariable()** service with the **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute set shall do the following prior to invoking the service:

1. Create a descriptor

Create an **EFI_VARIABLE_AUTHENTICATION_2** descriptor where:

- *TimeStamp* is set to the current time.

Note: *In certain environments a reliable time source may not be available. In this case, an implementation may still add values to an authenticated variable since the **EFI_VARIABLE_APPEND_WRITE** attribute, when set, disables timestamp verification (see below). In these instances, the special time value where every component of the **EFI_TIME** struct including the *Day* and *Month* is set to 0 shall be used.*

- *AuthInfo.CertType* is set to **EFI_CERT_TYPE_PKCS7_GUID**.

2. Hash the serialization

Hash the serialization of the values of the *VariableName*, *VendorGuid* and *Attributes* parameters of the **SetVariable()** call and the *TimeStamp* component of the **EFI_VARIABLE_AUTHENTICATION_2** descriptor followed by the variable's new value (i.e.

the *Data* parameter's new variable content). That is, $digest = hash(VariableName, VendorGuid, Attributes, TimeStamp, Data_{New_variable_content})$. The NULL character terminating the *VariableName* value shall not be included in the hash computation.

3. Sign the resulting digest
Sign the resulting digest using a selected signature scheme (e.g. PKCS #1 v1.5)
4. Construct a DER-encoded PKCS
Construct a DER-encoded PKCS #7 version 1.5 SignedData (see [RFC2315]) with the signed content as follows:
 - a SignedData.version shall be set to 1
 - b SignedData.digestAlgorithms shall contain the digest algorithm used when preparing the signature. Only a digest algorithm of SHA-256 is accepted.
 - c SignedData.contentInfo.contentType shall be set to id-data
 - d SignedData.contentInfo.content shall be absent (the content is provided in the *Data* parameter to the SetVariable() call)
 - e SignedData.certificates shall contain, at a minimum, the signer's DER-encoded X.509 certificate
 - f SignedData.crls is optional.
 - g SignedData.signerInfos shall be constructed as:
 - SignerInfo.version shall be set to 1
 - SignerInfo.issuerAndSerial shall be present and as in the signer's certificate
 - SignerInfo.authenticatedAttributes shall not be present.
 - SignerInfo.digestEncryptionAlgorithm shall be set to the algorithm used to sign the data. Only a digest encryption algorithm of RSA with PKCS #1 v1.5 padding (RSASSA_PKCS1-v1_5). is accepted.
 - SignerInfo.encryptedDigest shall be present
 - SignerInfo.unauthenticatedAttributes shall not be present.
5. Set AuthInfo.CertData
Set *AuthInfo.CertData* to the DER-encoded PKCS #7 SignedData value.
6. Construct Data parameter
Construct the **SetVariable()**'s *Data* parameter by concatenating the complete, serialized **EFI_VARIABLE_AUTHENTICATION_2** descriptor with the new value of the variable (*DataNew_variable_content*).

Firmware that implements the **SetVariable()** service and supports the **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** attribute shall do the following in response to being called:

1. Verify that the correct *AuthInfo.CertType* (**EFI_CERT_TYPE_PKCS7_GUID**) has been used and that the *AuthInfo.CertData* value parses correctly as a PKCS #7 SignedData value
2. Verify that Pad1, Nanosecond, TimeZone, Daylight and Pad2 components of the *TimeStamp* value are set to zero. Unless the **EFI_VARIABLE_APPEND_WRITE** attribute is set, verify that the *TimeStamp* value is later than the current timestamp value associated with the variable.

3. If the variable SetupMode==1, and the variable is a secure boot policy variable, then the firmware implementation shall consider the checks in the following steps 4 and 5 to have passed, and proceed with updating the variable value as outlined below.
4. Verify the signature by:
 - extracting the **EFI_VARIABLE_AUTHENTICATION_2** descriptor from the *Data* buffer;
 - using the descriptor contents and other parameters to
 - a construct the input to the digest algorithm;
 - b computing the digest; and
 - c comparing the digest with the result of applying the signer's public key to the signature.
5. If the variable is the global PK variable or the global KEK variable, verify that the signature has been made with the current Platform Key.

If the variable is the “db”, “dbt”, “dbr”, or “dbx” variable mentioned in step 3, verify that the signer's certificate chains to a certificate in the Key Exchange Key database (or that the signature was made with the current Platform Key).

If the variable is the "OsRecoveryOrder" variable mentioned in step 3, verify that the signer's certificate chains to a certificate in the "dbr" database, the Key Exchange Key database, or that the signature was made with the current Platform Key.

If the variable isn't one of the variables mentioned in step 3, and the variable previously existed, verify that the public key used to verify the signature is the public key already associated with the variable

The driver shall update the value of the variable only if all of these checks pass. If any of the checks fails, firmware must return **EFI_SECURITY_VIOLATION**.

The firmware shall perform an append to an existing variable value only if the **EFI_VARIABLE_APPEND_WRITE** attribute is set.

For variables with the GUID **EFI_IMAGE_SECURITY_DATABASE_GUID** (i.e. where the data buffer is formatted as **EFI_SIGNATURE_LIST**), the driver shall not perform an append of **EFI_SIGNATURE_DATA** values that are already part of the existing variable value .

Note: *This situation is not considered an error, and shall in itself not cause a status code other than **EFI_SUCCESS** to be returned or the timestamp associated with the variable not to be updated.*

The firmware shall associate the new timestamp with the updated value (in the case when the **EFI_VARIABLE_APPEND_WRITE** attribute is set, this only applies if the new *TimeStamp* value is later than the current timestamp associated with the variable).

If the variable did not previously exist, and is not one of the variables listed in step 3 above, then firmware shall associate the signer's public key with the variable for future verification purposes

7.2.2 Using the **EFI_VARIABLE_AUTHENTICATION** descriptor

When the attribute **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** is set, but the **EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS** is not set (i.e. when the **EFI_VARIABLE_AUTHENTICATION** descriptor is used), then the *Data* buffer shall begin with an instance of the authentication descriptor *AuthInfo* prior to the data payload and *DataSize* should reflect the data and descriptor size. The authentication descriptor is not part of the variable data and is not returned by the subsequent calls to *GetVariable*. The caller shall digest the

Monotonic Count value and the associated data for the variable update using the SHA-256 1-way hash algorithm. The ensuing the 32-byte digest will be signed using the private key associated w/ the public 2048-bit RSA key *PublicKey* described in the **EFI_CERT_BLOCK_RSA_2048_SHA256** structure.

The **WIN_CERTIFICATE** shall be used to describe the signature of the Variable data **Data*. In addition, the signature will also include the *MonotonicCount* value to guard against replay attacks. The *MonotonicCount* value must be increased by the caller prior to an update of the **Data* when the **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** is set.

From the **EFI_CERT_BLOCK_RSA_2048_SHA256**, the *HashType* will be **EFI_SHA256_HASH** and the **ANYSIZE_ARRAY** of *Signature* will be 256. The **WIN_CERTIFICATE_PKCS1_15** could have been used but was not for the following reason: There are possibly various different principals to create authenticated variables, so the public key corresponding to a given principal is added to the **EFI_CERT_BLOCK_RSA_2048_SHA256** within the **WIN_CERTIFICATE**. This does not lend cryptographic value so much as it provides something akin to a handle for the platform firmware to use during its verification operation.

The *MonotonicCount* value must be strictly greater for each successive variable update operation. This allows for ensuring freshness of the update operation and defense against replay attacks (i.e., if someone had the value of a former *AuthInfo*, such as a Man-in-the-Middle they could not re-invoke that same update session). For maintenance, the party who initially provisioned the variable (i.e., caller of *SetVariable*) and set the monotonic count will have to pass the credential (key-pair and monotonic count) to any party who is delegated to make successive updates to the variable with the **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** set. This 3-tuple of {public key, private key, monotonic count} becomes part of the management metadata for these access-controlled items.

The responsibility of the caller that invokes the **SetVariable()** service with the **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** attribute will do the following prior to invoking the service:

- Update the Monotonic Count value.
- Hash the variable contents (Data, Size, Monotonic count) using the *HashType* in the *AuthInfo* structure.
- Sign the resultant hash of above step using a caller private key and create the digital signature *Signature*. Ensure that the public key associated with signing private key is in the *AuthInfo* structure.
- Invoke *SetVariables* with **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** attribute set.

The responsibility of the firmware that implements the **SetVariable()** service and supports the **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** attribute will do the following in response to being called:

- The first time it uses *SetVariable* with the **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** attribute set. Use the public key in the *AuthInfo* structure for subsequent verification.
- Hash the variable contents (Data, Size, Monotonic count) using the *HashType* in the *AuthInfo* structure.

- Compare the public key in the *AuthInfo* structure with the public key passed in on the first invocation.
- Verify the digital signature *Signature* of the signed hash using the stored public key associated with the variable.
- Compare the verification of the signature with the instance generated by the caller
- If comparison fails, return **EFI_SECURITY_VIOLATION**.
- Compare the new monotonic count and ensure that it is greater than the last SetVariable operation with the **EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS** attribute set.
- If new monotonic count is not strictly greater, then return **EFI_SECURITY_VIOLATION**.

QueryVariableInfo()

Summary

Returns information about the EFI variables.

Prototype

```
typedef
EFI_STATUS
QueryVariableInfo (
    IN UINT32           Attributes,
    OUT UINT64          *MaximumVariableStorageSize,
    OUT UINT64          *RemainingVariableStorageSize,
    OUT UINT64          *MaximumVariableSize
);
```

Attributes Attributes bitmask to specify the type of variables on which to return information. Refer to the **GetVariable()** function description. The **EFI_VARIABLE_APPEND_WRITE** attribute, if set in the attributes bitmask, will be ignored.

MaximumVariableStorageSize On output the maximum size of the storage space available for the EFI variables associated with the attributes specified.

RemainingVariableStorageSize Returns the remaining size of the storage space available for EFI variables associated with the attributes specified.

MaximumVariableSize Returns the maximum size of an individual EFI variable associated with the attributes specified.

Description

The **QueryVariableInfo()** function allows a caller to obtain the information about the maximum size of the storage space available for the EFI variables, the remaining size of the storage space available for the EFI variables and the maximum size of each individual EFI variable, associated with the attributes specified.

The *MaximumVariableSize* value will reflect the overhead associated with the saving of a single EFI variable with the exception of the overhead associated with the length of the string name of the EFI variable.

The returned *MaximumVariableStorageSize*, *RemainingVariableStorageSize*, *MaximumVariableSize* information may change immediately after the call based on other runtime activities including asynchronous error events. Also, these values associated with different attributes are not additive in nature.

After the system has transitioned into runtime (after **ExitBootServices()** is called), an implementation may not be able to accurately return information about the Boot Services variable store. In such cases, **EFI_INVALID_PARAMETER** should be returned.

Status Codes Returned

EFI_SUCCESS	Valid answer returned.
EFI_INVALID_PARAMETER	An invalid combination of attribute bits was supplied
EFI_UNSUPPORTED	The attribute is not supported on this platform, and the <i>MaximumVariableStorageSize</i> , <i>RemainingVariableStorageSize</i> , <i>MaximumVariableSize</i> are undefined.

7.2.3 Hardware Error Record Persistence

This section defines how Hardware Error Record Persistence is to be implemented. By implementing support for Hardware Error Record Persistence, the platform enables the OS to utilize the EFI Variable Services to save hardware error records so they are persistent and remain available across OS sessions until they are explicitly cleared or overwritten by their creator.

7.2.3.1 Hardware Error Record Non-Volatile Store

A platform which implements support hardware error record persistence is required to guarantee some amount of NVR is available to the OS for saving hardware error records. The platform communicates the amount of space allocated for error records via the `QueryVariableInfo` routine as described in [Appendix P](#).

7.2.3.2 Hardware Error Record Variables

This section defines a set of Hardware Error Record variables that have architecturally defined meanings. In addition to the defined data content, each such variable has an architecturally defined attribute that indicates when the data variable may be accessed. The variables with an attribute of HR are stored in the portion of NVR allocated for error records. NV, BS and RT have the meanings defined in section 3.2. All hardware error record variables use the

EFI_HARDWARE_ERROR_VARIABLE VendorGuid:

```
#define EFI_HARDWARE_ERROR_VARIABLE\  
{0x414E6BDD, 0xE47B, 0x47cc, {0xB2, 0x44, 0xBB, 0x61, 0x02, 0x0C, 0xF5, 0x16}}
```

Table 35. Hardware Error Record Persistence Variables

Variable Name	Attribute	Description
HwErrRec####	NV, BS, RT, HR	A hardware error record. #### is a printed hex value. No 0x or h is included in the hex value

The HwErrRec#### variable contains a hardware error record. Each HwErrRec#### variable is the name "HwErrRec" appended with a unique 4-digit hexadecimal number. For example, HwErrRec0001, HwErrRec0002, HwErrRecF31A, etc. The HR attribute indicates that this variable is to be stored in the portion of NVR allocated for error records.

7.2.3.3 Common Platform Error Record Format

Error record variables persisted using this interface are encoded in the Common Platform Error Record format, which is described in appendix N of the *UEFI Specification*. Because error records

persisted using this interface conform to this standardized format, the error information may be used by entities other than the OS.

7.3 Time Services

This section contains function definitions for time-related functions that are typically needed by operating systems at runtime to access underlying hardware that manages time information and services. The purpose of these interfaces is to provide operating system writers with an abstraction for hardware time devices, thereby relieving the need to access legacy hardware devices directly. There is also a stalling function for use in the preboot environment. [Table 36](#) lists the time services functions described in this section:

Table 36. Time Services Functions

Name	Type	Description
GetTime	Runtime	Returns the current time and date, and the time-keeping capabilities of the platform.
SetTime	Runtime	Sets the current local time and date information.
GetWakeupTime	Runtime	Returns the current wakeup alarm clock setting.
SetWakeupTime	Runtime	Sets the system wakeup alarm clock time.

GetTime()

Summary

Returns the current time and date information, and the time-keeping capabilities of the hardware platform.

Prototype

```
typedef
EFI_STATUS
GetTime (
    OUT EFI_TIME                *Time,
    OUT EFI_TIME_CAPABILITIES  *Capabilities OPTIONAL
);
```

Parameters

<i>Time</i>	A pointer to storage to receive a snapshot of the current time. Type EFI_TIME is defined in “Related Definitions.”
<i>Capabilities</i>	An optional pointer to a buffer to receive the real time clock device’s capabilities. Type EFI_TIME_CAPABILITIES is defined in “Related Definitions.”

Related Definitions

```

//*****
//EFI_TIME
//*****
// This represents the current time information
typedef struct {
    UINT16    Year;        // 1900 - 9999
    UINT8     Month;      // 1 - 12
    UINT8     Day;        // 1 - 31
    UINT8     Hour;       // 0 - 23
    UINT8     Minute;     // 0 - 59
    UINT8     Second;     // 0 - 59
    UINT8     Pad1;
    UINT32    Nanosecond; // 0 - 999,999,999
    INT16     TimeZone;   // -1440 to 1440 or 2047
    UINT8     Daylight;
    UINT8     Pad2;
} EFI_TIME;

//*****
// Bit Definitions for EFI_TIME.Daylight. See below.
```

```

//*****
#define EFI_TIME_ADJUST_DAYLIGHT    0x01
#define EFI_TIME_IN_DAYLIGHT       0x02

//*****
// Value Definition for EFI_TIME.TimeZone. See below.
//*****
#define EFI_UNSPECIFIED_TIMEZONE    0x07FF

```

Year, Month, Day The current local date.

Hour, Minute, Second, Nanosecond

The current local time. Nanoseconds report the current fraction of a second in the device. The format of the time is *hh:mm:ss.nnnnnnnn*. A battery backed real time clock device maintains the date and time.

TimeZone

The time's offset in minutes from UTC. If the value is **EFI_UNSPECIFIED_TIMEZONE**, then the time is interpreted as a local time. The *TimeZone* is the number of minutes that the local time is relative to UTC. To calculate the *TimeZone* value, follow this equation: $Localtime = UTC - TimeZone$.

To further illustrate this, an example is given below:

PST (Pacific Standard Time is 12PM) = UTC (8PM) - 8 hours (480 minutes)

In this case, the value for *Timezone* would be 480 if referencing PST.

Daylight

A bitmask containing the daylight savings time information for the time.

The **EFI_TIME_ADJUST_DAYLIGHT** bit indicates if the time is affected by daylight savings time or not. This value does not indicate that the time has been adjusted for daylight savings time. It indicates only that it should be adjusted when the **EFI_TIME** enters daylight savings time.

If **EFI_TIME_IN_DAYLIGHT** is set, the time has been adjusted for daylight savings time.

All other bits must be zero.

When entering daylight saving time, if the time is affected, but hasn't been adjusted (DST = 1), use the new calculation:

1. The date/time should be increased by the appropriate amount.
2. The *TimeZone* should be decreased by the appropriate amount (EX: +480 changes to +420 when moving from PST to PDT).
3. The *Daylight* value changes to 3.

When exiting daylight saving time, if the time is affected and has been adjusted (DST = 3), use the new calculation:

1. The date/time should be decreased by the appropriate amount.
2. The *TimeZone* should be increased by the appropriate amount.
3. The *Daylight* value changes to 1.

```

//*****
// EFI_TIME_CAPABILITIES
//*****
// This provides the capabilities of the
// real time clock device as exposed through the EFI interfaces.
typedef struct {
    UINT32      Resolution;
    UINT32      Accuracy;
    BOOLEAN     SetsToZero;
} EFI_TIME_CAPABILITIES;

```

Resolution Provides the reporting resolution of the real-time clock device in counts per second. For a normal PC-AT CMOS RTC device, this value would be 1 Hz, or 1, to indicate that the device only reports the time to the resolution of 1 second.

Accuracy Provides the timekeeping accuracy of the real-time clock in an error rate of 1E-6 parts per million. For a clock with an accuracy of 50 parts per million, the value in this field would be 50,000,000.

SetsToZero A **TRUE** indicates that a time set operation clears the device’s time below the *Resolution* reporting level. A **FALSE** indicates that the state below the *Resolution* level of the device is not cleared when the time is set. Normal PC-AT CMOS RTC devices set this value to **FALSE**.

Description

The **GetTime ()** function returns a time that was valid sometime during the call to the function. While the returned **EFI_TIME** structure contains *TimeZone* and *Daylight* savings time information, the actual clock does not maintain these values. The current time zone and daylight saving time information returned by **GetTime ()** are the values that were last set via [SetTime \(\)](#).

The **GetTime ()** function should take approximately the same amount of time to read the time each time it is called. All reported device capabilities are to be rounded up.

During runtime, if a PC-AT CMOS device is present in the platform the caller must synchronize access to the device before calling **GetTime ()**.

Status Codes Returned

EFI_SUCCESS	The operation completed successfully.
EFI_INVALID_PARAMETER	<i>Time</i> is NULL .

Unified Extensible Firmware Interface Specification

EFI_DEVICE_ERROR	The time could not be retrieved due to a hardware error.
------------------	--

SetTime()

Summary

Sets the current local time and date information.

Prototype

```
typedef
EFI_STATUS
SetTime (
    IN EFI_TIME      *Time
);
```

Parameters

Time A pointer to the current time. Type **EFI_TIME** is defined in the [GetTime\(\)](#) function description. Full error checking is performed on the different fields of the **EFI_TIME** structure (refer to the **EFI_TIME** definition in the [GetTime\(\)](#) function description for full details), and **EFI_INVALID_PARAMETER** is returned if any field is out of range.

Description

The **SetTime()** function sets the real time clock device to the supplied time, and records the current time zone and daylight savings time information. The **SetTime()** function is not allowed to loop based on the current time. For example, if the device does not support a hardware reset for the sub-resolution time, the code is *not* to implement the feature by waiting for the time to wrap.

During runtime, if a PC-AT CMOS device is present in the platform the caller must synchronize access to the device before calling **SetTime()**.

Status Codes Returned

EFI_SUCCESS	The operation completed successfully.
EFI_INVALID_PARAMETER	A time field is out of range.
EFI_DEVICE_ERROR	The time could not be set due to a hardware error.

GetWakeupTime()

Summary

Returns the current wakeup alarm clock setting.

Prototype

```
typedef
EFI_STATUS
GetWakeupTime (
    OUT BOOLEAN    *Enabled,
    OUT BOOLEAN    *Pending,
    OUT EFI_TIME   *Time
);
```

Parameters

<i>Enabled</i>	Indicates if the alarm is currently enabled or disabled.
<i>Pending</i>	Indicates if the alarm signal is pending and requires acknowledgement.
<i>Time</i>	The current alarm setting. Type EFI_TIME is defined in the GetTime() function description.

Description

The alarm clock time may be rounded from the set alarm clock time to be within the resolution of the alarm clock device. The resolution of the alarm clock device is defined to be one second.

During runtime, if a PC-AT CMOS device is present in the platform the caller must synchronize access to the device before calling **GetWakeupTime()**.

Status Codes Returned

EFI_SUCCESS	The alarm settings were returned.
EFI_INVALID_PARAMETER	<i>Enabled</i> is NULL .
EFI_INVALID_PARAMETER	<i>Pending</i> is NULL .
EFI_INVALID_PARAMETER	<i>Time</i> is NULL .
EFI_DEVICE_ERROR	The wakeup time could not be retrieved due to a hardware error.
EFI_UNSUPPORTED	A wakeup timer is not supported on this platform.

SetWakeupTime()

Summary

Sets the system wakeup alarm clock time.

Prototype

```
typedef
EFI_STATUS
SetWakeupTime (
    IN BOOLEAN    Enable,
    IN EFI_TIME   *Time           OPTIONAL
);
```

Parameters

Enable

Enable or disable the wakeup alarm.

Time

If *Enable* is **TRUE**, the time to set the wakeup alarm for. Type **EFI_TIME** is defined in the [GetTime\(\)](#) function description. If *Enable* is **FALSE**, then this parameter is optional, and may be **NULL**.

Description

Setting a system wakeup alarm causes the system to wake up or power on at the set time. When the alarm fires, the alarm signal is latched until it is acknowledged by calling **SetWakeupTime()** to disable the alarm. If the alarm fires before the system is put into a sleeping or off state, since the alarm signal is latched the system will immediately wake up. If the alarm fires while the system is off and there is insufficient power to power on the system, the system is powered on when power is restored.

For an ACPI-aware operating system, this function only handles programming the wakeup alarm for the desired wakeup time. The operating system still controls the wakeup event as it normally would through the ACPI Power Management register set.

The resolution for the wakeup alarm is defined to be 1 second.

During runtime, if a PC-AT CMOS device is present in the platform the caller must synchronize access to the device before calling **SetWakeupTime()**.

Status Codes Returned

EFI_SUCCESS	If <i>Enable</i> is TRUE , then the wakeup alarm was enabled. If <i>Enable</i> is FALSE , then the wakeup alarm was disabled.
EFI_INVALID_PARAMETER	A time field is out of range.
EFI_DEVICE_ERROR	The wakeup time could not be set due to a hardware error.
EFI_UNSUPPORTED	A wakeup timer is not supported on this platform.

7.4 Virtual Memory Services

This section contains function definitions for the virtual memory support that may be optionally used by an operating system at runtime. If an operating system chooses to make EFI runtime service calls in a virtual addressing mode instead of the flat physical mode, then the operating system must use the services in this section to switch the EFI runtime services from flat physical addressing to virtual addressing. [Table 37](#) lists the virtual memory service functions described in this section. The system firmware must follow the processor-specific rules outlined in [Section 2.3.2](#) through [Section 2.3.6](#) in the layout of the EFI memory map to enable the OS to make the required virtual mappings.

Table 37. Virtual Memory Functions

Name	Type	Description
SetVirtualAddressMap	Runtime	Used by an OS loader to convert from physical addressing to virtual addressing.
ConvertPointer	Runtime	Used by EFI components to convert internal pointers when switching to virtual addressing.

SetVirtualAddressMap()

Summary

Changes the runtime addressing mode of EFI firmware from physical to virtual.

Prototype

```
typedef
EFI_STATUS
SetVirtualAddressMap (
    IN UINTN                MemoryMapSize,
    IN UINTN                DescriptorSize,
    IN UINT32              DescriptorVersion,
    IN EFI_MEMORY_DESCRIPTOR *VirtualMap
);
```

Parameters

<i>MemoryMapSize</i>	The size in bytes of <i>VirtualMap</i> .
<i>DescriptorSize</i>	The size in bytes of an entry in the <i>VirtualMap</i> .
<i>DescriptorVersion</i>	The version of the structure entries in <i>VirtualMap</i> .
<i>VirtualMap</i>	An array of memory descriptors which contain new virtual address mapping information for all runtime ranges. Type EFI_MEMORY_DESCRIPTOR is defined in the EFI_BOOT_SERVICES.GetMemoryMap() function description.

Description

The **SetVirtualAddressMap()** function is used by the OS loader. The function can only be called at runtime, and is called by the owner of the system's memory map: i.e., the component which called [EFI_BOOT_SERVICES.ExitBootServices\(\)](#). All events of type **EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE** must be signaled before **SetVirtualAddressMap()** returns.

This call changes the addresses of the runtime components of the EFI firmware to the new virtual addresses supplied in the *VirtualMap*. The supplied *VirtualMap* must provide a new virtual address for every entry in the memory map at **ExitBootServices()** that is marked as being needed for runtime usage. All of the virtual address fields in the *VirtualMap* must be aligned on 4 KiB boundaries.

The call to **SetVirtualAddressMap()** must be done with the physical mappings. On successful return from this function, the system must then make any future calls with the newly assigned virtual mappings. All address space mappings must be done in accordance to the cacheability flags as specified in the original address map.

When this function is called, all events that were registered to be signaled on an address map change are notified. Each component that is notified must update any internal pointers for their new addresses. This can be done with the [ConvertPointer\(\)](#) function. Once all events have been notified, the EFI firmware reapplies image “fix-up” information to virtually relocate all runtime

images to their new addresses. In addition, all of the fields of the EFI Runtime Services Table except *SetVirtualAddressMap* and *ConvertPointer* must be converted from physical pointers to virtual pointers using the **ConvertPointer()** service. The **SetVirtualAddressMap()** and **ConvertPointer()** services are only callable in physical mode, so they do not need to be converted from physical pointers to virtual pointers. Several fields of the EFI System Table must be converted from physical pointers to virtual pointers using the **ConvertPointer()** service. These fields include *FirmwareVendor*, *RuntimeServices*, and *ConfigurationTable*. Because contents of both the EFI Runtime Services Table and the EFI System Table are modified by this service, the 32-bit CRC for the EFI Runtime Services Table and the EFI System Table must be recomputed.

A virtual address map may only be applied one time. Once the runtime system is in virtual mode, calls to this function return **EFI_UNSUPPORTED**.

Status Codes Returned

EFI_SUCCESS	The virtual address map has been applied.
EFI_UNSUPPORTED	EFI firmware is not at runtime, or the EFI firmware is already in virtual address mapped mode.
EFI_INVALID_PARAMETER	<i>DescriptorSize</i> or <i>DescriptorVersion</i> is invalid.
EFI_NO_MAPPING	A virtual address was not supplied for a range in the memory map that requires a mapping.
EFI_NOT_FOUND	A virtual address was supplied for an address that is not found in the memory map.

ConvertPointer()

Summary

Determines the new virtual address that is to be used on subsequent memory accesses.

Prototype

```
typedef
EFI_STATUS
ConvertPointer (
    IN UINTN   DebugDisposition,
    IN VOID    **Address
);
```

Parameters

<i>DebugDisposition</i>	Supplies type information for the pointer being converted. See “Related Definitions.”
<i>Address</i>	A pointer to a pointer that is to be fixed to be the value needed for the new virtual address mappings being applied.

Related Definitions

```

//*****
// EFI_OPTIONAL_PTR
//*****
#define EFI_OPTIONAL_PTR          0x00000001
```

Description

The **ConvertPointer()** function is used by an EFI component during the [SetVirtualAddressMap\(\)](#) operation. **ConvertPointer()** must be called using physical address pointers during the execution of **SetVirtualAddressMap()**.

The **ConvertPointer()** function updates the current pointer pointed to by *Address* to be the proper value for the new address map. Only runtime components need to perform this operation. The [EFI_BOOT_SERVICES.CreateEvent\(\)](#) function is used to create an event that is to be notified when the address map is changing. All pointers the component has allocated or assigned must be updated.

If the **EFI_OPTIONAL_PTR** flag is specified, the pointer being converted is allowed to be **NULL**. Once all components have been notified of the address map change, firmware fixes any compiled in pointers that are embedded in any runtime image.

Status Codes Returned

EFI_SUCCESS	The pointer pointed to by <i>Address</i> was modified.
EFI_NOT_FOUND	The pointer pointed to by <i>Address</i> was not found to be part of the current memory map. This is normally fatal.
EFI_INVALID_PARAMETER	<i>Address</i> is NULL .
EFI_INVALID_PARAMETER	* <i>Address</i> is NULL and <i>DebugDisposition</i> does not have the EFI_OPTIONAL_PTR bit set.

7.5 Miscellaneous Runtime Services

This section contains the remaining function definitions for runtime services not defined elsewhere but which are required to complete the definition of the EFI environment. [Table 38](#) lists the Miscellaneous Runtime Services.

Table 38. Miscellaneous Runtime Services

Name	Type	Description
GetNextHighMonotonicCount	Runtime	Returns the next high 32 bits of the platform’s monotonic counter.
ResetSystem	Runtime	Resets the entire platform.
UpdateCapsule	Runtime	Pass capsules to the firmware. The firmware may process the capsules immediately or return a value to be passed into ResetSystem() that will cause the capsule to be processed by the firmware as part of the reset process.
QueryCapsuleCapabilities	Runtime	Returns if the capsule can be supported via UpdateCapsule()

7.5.1 Reset System

This section describes the reset system runtime service and its associated data structures.

ResetSystem()

Summary

Resets the entire platform.

Prototype

```
typedef
VOID
ResetSystem (
    IN EFI_RESET_TYPE   ResetType,
    IN EFI_STATUS        ResetStatus,
    IN UINTN             DataSize,
    IN VOID              *ResetData OPTIONAL
);
```

Parameters

<i>ResetType</i>	The type of reset to perform. Type EFI_RESET_TYPE is defined in “Related Definitions” below.
<i>ResetStatus</i>	The status code for the reset. If the system reset is part of a normal operation, the status code would be EFI_SUCCESS . If the system reset is due to some type of failure the most appropriate EFI Status code would be used.
<i>DataSize</i>	The size, in bytes, of <i>ResetData</i> .
<i>ResetData</i>	For a <i>ResetType</i> of EfiResetCold , EfiResetWarm , or EfiResetShutdown the data buffer starts with a Null-terminated string, optionally followed by additional binary data. The string is a description that the caller may use to further indicate the reason for the system reset. <i>ResetData</i> is only valid if <i>ResetStatus</i> is something other than EFI_SUCCESS unless the <i>ResetType</i> is <i>EfiResetPlatformSpecific</i> where a minimum amount of <i>ResetData</i> is always required. For a <i>ResetType</i> of EfiRestUpdate the data buffer also starts with a Null-terminated string that is followed by an EFI_GUID that describes the specific type of reset to perform.

Related Definitions

```

//*****
// EFI_RESET_TYPE
//*****
typedef enum {
    EfiResetCold,
    EfiResetWarm,
    EfiResetShutdown
    EfiResetPlatformSpecific
} EFI_RESET_TYPE;

```

Description

The **ResetSystem()** function resets the entire platform, including all processors and devices, and reboots the system.

Calling this interface with *ResetType* of **EfiResetCold** causes a system-wide reset. This sets all circuitry within the system to its initial state. This type of reset is asynchronous to system operation and operates without regard to cycle boundaries. **EfiResetCold** is tantamount to a system power cycle.

Calling this interface with *ResetType* of **EfiResetWarm** causes a system-wide initialization. The processors are set to their initial state, and pending cycles are not corrupted. If the system does not support this reset type, then an **EfiResetCold** must be performed.

Calling this interface with *ResetType* of **EfiResetShutdown** causes the system to enter a power state equivalent to the ACPI G2/S5 or G3 states. If the system does not support this reset type, then when the system is rebooted, it should exhibit the **EfiResetCold** attributes.

Calling this interface with *ResetType* of **EfiResetPlatformSpecific** causes a system-wide reset. The exact type of the reset is defined by the **EFI_GUID** that follows the Null-terminated Unicode string passed into *ResetData*. If the platform does not recognize the **EFI_GUID** in *ResetData* the platform must pick a supported reset type to perform. The platform may optionally log the parameters from any non-normal reset that occurs.

The **ResetSystem()** function does not return.

7.5.2 Get Next High Monotonic Count

This section describes the GetNextHighMonotonicCount runtime service and its associated data structures.

GetNextHighMonotonicCount()

Summary

Returns the next high 32 bits of the platform's monotonic counter.

Prototype

```
typedef
EFI_STATUS
GetNextHighMonotonicCount (
    OUT UINT32    *HighCount
);
```

Parameters

HighCount Pointer to returned value.

Description

The **GetNextHighMonotonicCount()** function returns the next high 32 bits of the platform's monotonic counter.

The platform's monotonic counter is comprised of two 32-bit quantities: the high 32 bits and the low 32 bits. During boot service time the low 32-bit value is volatile: it is reset to zero on every system reset and is increased by 1 on every call to **GetNextMonotonicCount()**. The high 32-bit value is nonvolatile and is increased by 1 whenever the system resets, whenever **GetNextHighMonotonicCount()** is called, or whenever the low 32-bit count (returned by **GetNextMonotonicCount()**) overflows.

The [EFI_BOOT_SERVICES.GetNextMonotonicCount\(\)](#) function is only available at boot services time. If the operating system wishes to extend the platform monotonic counter to runtime, it may do so by utilizing **GetNextHighMonotonicCount()**. To do this, before calling [EFI_BOOT_SERVICES.ExitBootServices\(\)](#) the operating system would call **GetNextMonotonicCount()** to obtain the current platform monotonic count. The operating system would then provide an interface that returns the next count by:

- Adding 1 to the last count.
- Before the lower 32 bits of the count overflows, call **GetNextHighMonotonicCount()**. This will increase the high 32 bits of the platform's nonvolatile portion of the monotonic count by 1.

This function may only be called at Runtime.

Status Codes Returned

EFI_SUCCESS	The next high monotonic count was returned.
EFI_DEVICE_ERROR	The device is not functioning properly.
EFI_INVALID_PARAMETER	<i>HighCount</i> is NULL .

7.5.3 Update Capsule

This runtime function allows a caller to pass information to the firmware. Update Capsule is commonly used to update the firmware FLASH or for an operating system to have information persist across a system reset.

UpdateCapsule()

Summary

Passes capsules to the firmware with both virtual and physical mapping. Depending on the intended consumption, the firmware may process the capsule immediately. If the payload should persist across a system reset, the reset value returned from *EFI_QueryCapsuleCapabilities* must be passed into [ResetSystem\(\)](#) and will cause the capsule to be processed by the firmware as part of the reset process.

Prototype

```
typedef
EFI_STATUS
UpdateCapsule (
    IN EFI_CAPSULE_HEADER    **CapsuleHeaderArray,
    IN UINTN                 CapsuleCount,
    IN EFI_PHYSICAL_ADDRESS  ScatterGatherList OPTIONAL
);
```

Parameters

CapsuleHeaderArray Virtual pointer to an array of virtual pointers to the capsules being passed into update capsule. Each capsules is assumed to stored in contiguous virtual memory. The capsules in the *CapsuleHeaderArray* must be the same capsules as the *ScatterGatherList*. The *CapsuleHeaderArray* must have the capsules in the same order as the *ScatterGatherList*.

CapsuleCount Number of pointers to **EFI_CAPSULE_HEADER** in *CapsuleHeaderArray*.

ScatterGatherList Physical pointer to a set of **EFI_CAPSULE_BLOCK_DESCRIPTOR** that describes the location in physical memory of a set of capsules. See "Related Definitions" for an explanation of how more than one capsule is passed via this interface. The capsules in the *ScatterGatherList* must be in the same order as the *CapsuleHeaderArray*. This parameter is only referenced if the capsules are defined to persist across system reset.

Related Definitions

```
typedef struct {
    UINT64                Length;
    union {
        EFI_PHYSICAL_ADDRESS  DataBlock;
        EFI_PHYSICAL_ADDRESS  ContinuationPointer;
    }Union;
} EFI_CAPSULE_BLOCK_DESCRIPTOR;
```

Length Length in bytes of the data pointed to by *DataBlock/ContinuationPointer*.

DataBlock Physical address of the data block. This member of the union is used if *Length* is not equal to zero.

ContinuationPointer Physical address of another block of **EFI_CAPSULE_BLOCK_DESCRIPTOR** structures. This member of the union is used if *Length* is equal to zero. If *ContinuationPointer* is zero this entry represents the end of the list.

This data structure defines the *ScatterGatherList* list the OS passes to the firmware. *ScatterGatherList* represents an array of structures and is terminated with a structure member whose *Length* is 0 and *DataBlock* physical address is 0. If *Length* is 0 and *DataBlock* physical address is not 0, the specified physical address is known as a “continuation pointer” and it points to a further list of **EFI_CAPSULE_BLOCK_DESCRIPTOR** structures. A continuation pointer is used to allow the scatter gather list to be contained in physical memory that is not contiguous. It also is used to allow more than a single capsule to be passed at one time.

```
typedef struct {
    EFI_GUID    CapsuleGuid;
    UINT32     HeaderSize;
    UINT32     Flags;
    UINT32     CapsuleImageSize;
} EFI_CAPSULE_HEADER;
```

CapsuleGuid A GUID that defines the contents of a capsule.

HeaderSize The size of the capsule header. This may be larger than the size of the **EFI_CAPSULE_HEADER** since *CapsuleGuid* may imply extended header entries.

Flags Bit-mapped list describing the capsule attributes. The Flag values of 0x0000 – 0xFFFF are defined by *CapsuleGuid*. Flag values of 0x10000 – 0xFFFFFFFF are defined by this specification

CapsuleImageSize Size in bytes of the capsule.

```
#define CAPSULE_FLAGS_PERSIST_ACROSS_RESET    0x00010000
#define CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE  0x00020000
#define CAPSULE_FLAGS_INITIATE_RESET        0x00040000
```

Note: A capsule which has the *CAPSULE_FLAGS_INITIATE_RESET* Flag must have *CAPSULE_FLAGS_PERSIST_ACROSS_RESET* set in its header as well. Firmware that encounters a capsule which has the *CAPSULE_FLAGS_INITIATE_RESET* Flag set in its header

will initiate a reset of the platform which is compatible with the passed-in capsule request and will not return back to the caller.

Description

The **UpdateCapsule()** function allows the operating system to pass information to firmware. The **UpdateCapsule()** function supports passing capsules in operating system virtual memory back to firmware. Each capsule is contained in a contiguous virtual memory range in the operating system, but both a virtual and physical mapping for the capsules are passed to the firmware.

If a capsule has the `CAPSULE_FLAGS_PERSIST_ACROSS_RESET` *Flag* set in its header, the firmware will process the capsules after system reset. The caller must ensure to reset the system using the required reset value obtained from `QueryCapsuleCapabilities`. If this flag is not set, the firmware will process the capsules immediately.

A capsule which has the `CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE` *Flag* must have `CAPSULE_FLAGS_PERSIST_ACROSS_RESET` set in its header as well. Firmware that processes a capsule that has the `CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE` *Flag* set in its header will coalesce the contents of the capsule from the `ScatterGatherList` into a contiguous buffer and must then place a pointer to this coalesced capsule in the EFI System Table after the system has been reset. Agents searching for this capsule will look in the `EFI_CONFIGURATION_TABLE` and search for the capsule’s GUID and associated pointer to retrieve the data after the reset.

Table 39. Flag Firmware Behavior

Flags	Firmware Behavior
No Specification defined flags	Firmware attempts to immediately processes or launch the capsule. If capsule is not recognized, can expect an error.
<code>CAPSULE_FLAGS_PERSIST_ACROSS_RESET</code>	Firmware will attempt to process or launch the capsule across a reset. If capsule is not recognized, can expect an error. If the processing requires a reset which is unsupported by the platform, expect an error.
<code>CAPSULE_FLAGS_PERSIST_ACROSS_RESET + CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE</code>	Firmware will coalesce the capsule from the <code>ScatterGatherList</code> into a contiguous buffer and place a pointer to the coalesced capsule in the EFI System Table. Platform recognition of the capsule type is not required. If the action requires a reset which is unsupported by the platform, expect an error.
<code>CAPSULE_FLAGS_PERSIST_ACROSS_RESET + CAPSULE_FLAGS_INITIATE_RESET</code>	Firmware will attempt to process or launch the capsule across a reset. The firmware will initiate a reset which is compatible with the passed-in capsule request and will not return back to the caller. If the capsule is not recognized, can expect an error. If the processing requires a reset which is unsupported by the platform, expect an error.

Flags	Firmware Behavior
CAPSULE_FLAGS_PERSIST_ACROSS_RESET + CAPSULE_FLAGS_INITIATE_RESET + CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE	The firmware will initiate a reset which is compatible with the passed-in capsule request and not return back to the caller. Upon resetting, the firmware will coalesce the capsule from the ScatterGatherList into a contiguous buffer and place a pointer to the coalesced capsule in the EFI System Table. Platform recognition of the capsule type is not required. If the action requires a reset which is unsupported by the platform, expect an error.

The EFI System Table entry must use the GUID from the **CapsuleGuid** field of the **EFI_CAPSULE_HEADER**. The EFI System Table entry must point to an array of capsules that contain the same **CapsuleGuid** value. The array must be prefixed by a **UINT32** that represents the size of the array of capsules.

The set of capsules is pointed to by **ScatterGatherList** and **CapsuleHeaderArray** so the firmware will know both the physical and virtual addresses of the operating system allocated buffers. The scatter-gather list supports the situation where the virtual address range of a capsule is contiguous, but the physical addresses are not.

If any of the capsules that are passed into this function encounter an error, the entire set of capsules will not be processed and the error encountered will be returned to the caller.

Status Codes Returned

EFI_SUCCESS	Valid capsule was passed. If CAPSULE_FLAGS_PERSIST_ACROSS_RESET is not set, the capsule has been successfully processed by the firmware.
EFI_INVALID_PARAMETER	<i>CapsuleSize</i> , or an incompatible set of flags were set in the capsule header.
EFI_INVALID_PARAMETER	<i>CapsuleCount</i> is 0
EFI_DEVICE_ERROR	The capsule update was started, but failed due to a device error.
EFI_UNSUPPORTED	The capsule type is not supported on this platform.
EFI_OUT_OF_RESOURCES	When ExitBootServices () has been previously called this error indicates the capsule is compatible with this platform but is not capable of being submitted or processed in runtime. The caller may resubmit the capsule prior to ExitBootServices () .
EFI_OUT_OF_RESOURCES	When ExitBootServices () has not been previously called then this error indicates the capsule is compatible with this platform but there are insufficient resources to process.

7.5.3.1 Capsule Definition

A capsule is simply a contiguous set of data that starts with an **EFI_CAPSULE_HEADER**. The *CapsuleGuid* field in the header defines the format of the capsule.

The capsule contents are designed to be communicated from an OS-present environment to the system firmware. To allow capsules to persist across system reset, a level of indirection is required for the description of a capsule, since the OS primarily uses virtual memory and the firmware at boot time uses physical memory. This level of abstraction is accomplished via the **EFI_CAPSULE_BLOCK_DESCRIPTOR**. The **EFI_CAPSULE_BLOCK_DESCRIPTOR** allows the OS to allocate contiguous virtual address space and describe this address space to the firmware as a discontinuous set of physical address ranges. The firmware is passed both physical and virtual addresses and pointers to describe the capsule so the firmware can process the capsule immediately or defer processing of the capsule until after a system reset.

In most instruction sets and OS architecture, allocation of physical memory is possible only on a “page” granularity (which can range for 4 KiB to at least 1 MiB). The **EFI_CAPSULE_BLOCK_DESCRIPTOR** must have the following properties to ensure the safe and well defined transition of the data:

- Each new capsule must start on a new page of memory.
- All pages except for the last must be completely filled by the capsule.
 - It is legal to pad the header to make it consume an entire page of data to enable the passing of page aligned data structures via a capsule. The last page must have at least one byte of capsule in it.
- Pages must be naturally aligned
- Pages may not overlap on another
- Firmware may never make an assumption about the page sizes the operating system is using.

Multiple capsules can be concatenated together and passed via a single call to **UpdateCapsule()**. The physical address description of capsules are concatenated by converting the terminating **EFI_CAPSULE_BLOCK_DESCRIPTOR** entry of the 1st capsule into a continuation pointer by making it point to the **EFI_CAPSULE_BLOCK_DESCRIPTOR** that represents the start of the 2nd capsule. There is only a single terminating **EFI_CAPSULE_BLOCK_DESCRIPTOR** entry and it is at the end of the last capsule in the chain.

The following algorithm must be used to find multiple capsules in a single scatter gather list:

- Look at the capsule header to determine the size of the capsule
 - The first Capsule header is always pointed to by the first **EFI_CAPSULE_BLOCK_DESCRIPTOR** entry
- Walk the **EFI_CAPSULE_BLOCK_DESCRIPTOR** list keeping a running count of the size each entry represents.
- If the **EFI_CAPSULE_BLOCK_DESCRIPTOR** entry is a continuation pointer and the running current capsule size count is greater than or equal to the size of the current capsule this is the start of the next capsule.
- Make the new capsules the current capsule and repeat the algorithm.

[Figure 22](#) shows a Scatter-Gather list of **EFI_CAPSULE_BLOCK_DESCRIPTOR** structures that describes two capsules. The left side of the figure shows OS view of the capsules as two separate contiguous virtual memory buffers. The center of the figure shows the layout of the data in system memory. The right hand side of the figure shows the *ScatterGatherList* list passed into the

firmware. Since there are two capsules two independent **EFI_CAPSULE_BLOCK_DESCRIPTOR** lists exist that were joined together via a continuation pointer in the first list.

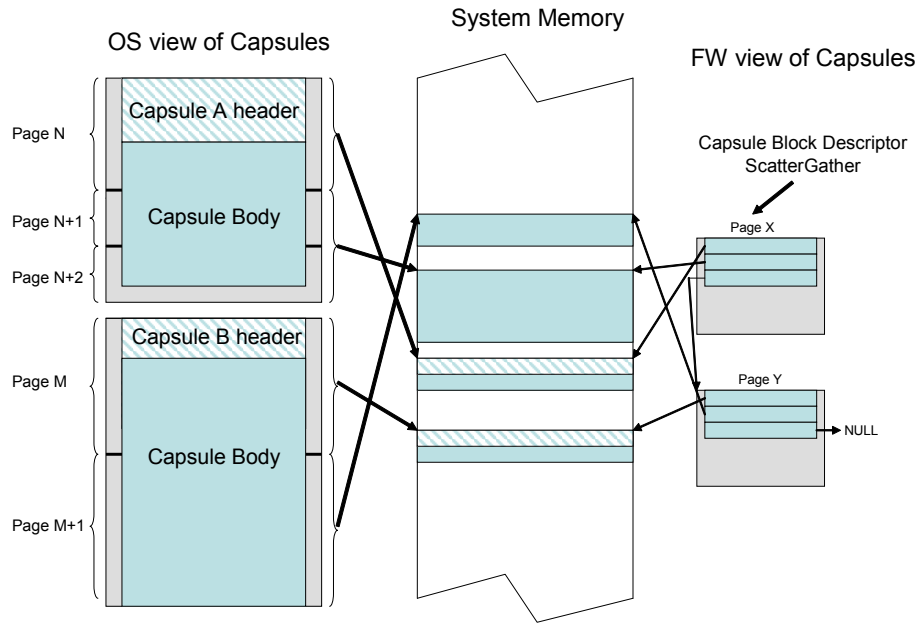

Figure 22. Scatter-Gather List of **EFI_CAPSULE_BLOCK_DESCRIPTOR** Structures

QueryCapsuleCapabilities()

Summary

Returns if the capsule can be supported via **UpdateCapsule()**.

Prototype

```
typedef
EFI_STATUS
QueryCapsuleCapabilities (
    IN EFI_CAPSULE_HEADER  **CapsuleHeaderArray,
    IN UINTN                CapsuleCount,
    OUT UINT64              *MaximumCapsuleSize,
    OUT EFI_RESET_TYPE      *ResetType
);
```

CapsuleHeaderArray

Virtual pointer to an array of virtual pointers to the capsules being passed into update capsule. The capsules are assumed to stored in contiguous virtual memory.

CapsuleCount

Number of pointers to **EFI_CAPSULE_HEADER** in *CapsuleHeaderArray*.

MaximumCapsuleSize

On output the maximum size in bytes that **UpdateCapsule()** can support as an argument to **UpdateCapsule()** via *CapsuleHeaderArray* and *ScatterGatherList*. Undefined on input.

ResetType

Returns the type of reset required for the capsule update. Undefined on input.

Description

The **QueryCapsuleCapabilities()** function allows a caller to test to see if a capsule or capsules can be updated via **UpdateCapsule()**. The Flags values in the capsule header and size of the entire capsule is checked.

If the caller needs to query for generic capsule capability a fake **EFI_CAPSULE_HEADER** can be constructed where *CapsuleImageSize* is equal to *HeaderSize* that is equal to sizeof (**EFI_CAPSULE_HEADER**). To determine reset requirements, **CAPSULE_FLAGS_PERSIST_ACROSS_RESET** should be set in the *Flags* field of the **EFI_CAPSULE_HEADER**.

Status Codes Returned

EFI_SUCCESS	Valid answer returned.
EFI_INVALID_PARAMETER	<i>MaximumCapsuleSize</i> is NULL .
EFI_UNSUPPORTED	The capsule type is not supported on this platform, and <i>MaximumCapsuleSize</i> and <i>ResetType</i> are undefined.
EFI_OUT_OF_RESOURCES	When ExitBootServices () has been previously called this error indicates the capsule is compatible with this platform but is not capable of being submitted or processed in runtime. The caller may resubmit the capsule prior to ExitBootServices () .
EFI_OUT_OF_RESOURCES	When ExitBootServices () has not been previously called then this error indicates the capsule is compatible with this platform but there are insufficient resources to process.

7.5.4 Exchanging information between the OS and Firmware

The firmware and an Operating System may exchange information through the *OsIndicationsSupported* and the *OSIndications* variables as follows:

- The *OsIndications* variable returns a UINT64 bitmask owned by the OS and is used to indicate which features the OS wants firmware to enable or which actions the OS wants the firmware to take. The OS will supply this data with a **SetVariable ()** call.
- The *OsIndicationsSupported* variable returns a UINT64 bitmask owned by the firmware and indicates which of the OS indication features and actions that the firmware supports. This variable is recreated by firmware every boot, and cannot be modified by the OS .

The **EFI_OS_INDICATIONS_BOOT_TO_FW_UI** bit can be set in the *OsIndicationsSupported* variable by the firmware, if the firmware supports OS requests to stop at a firmware user interface. The **EFI_OS_INDICATIONS_BOOT_TO_FW_UI** bit can be set by the OS in the *OsIndications* variable, if the OS desires for the firmware to stop at a firmware user interface on the next boot. Once the firmware consumes this bit in the *OsIndications* variable and stops at the firmware user interface, the firmware should clear the bit from the *OsIndications* variable in order to acknowledge to the OS that the information was consumed and, more importantly, to prevent the firmware user interface from showing again on subsequent boots.

The **EFI_OS_INDICATIONS_TIMESTAMP_REVOCATION** bit can be set in the *OSIndicationsSupported* variable by the firmware, if the firmware supports timestamp based revocation and the "dbt" authorized timestamp database variable.

The **EFI_OS_INDICATIONS_FMP_CAPSULE_SUPPORTED** bit is set in *OsIndicationsSupported* variable if platform supports processing of Firmware Management Protocol update capsule as defined in [Section 22.2](#). If set in *OsIndications* variable, the **EFI_OS_INDICATIONS_FMP_CAPSULE_SUPPORTED** bit has no function and is cleared on the next reboot.

The **EFI_OS_INDICATIONS_FILE_CAPSULE_DELIVERY_SUPPORTED** bit in *OsIndicationsSupported* variable is set if platform supports processing of file capsules per [Section 7.5.5](#).

When submitting capsule via the Mass Storage Device method of [Section 7.5.5](#), the bit **EFI_OS_INDICATIONS_FILE_CAPSULE_DELIVERY_SUPPORTED** in *OsIndications* variable must be set by submitter to trigger processing of submitted capsule on next reboot. This bit will be cleared from *OsIndications* by system firmware in all cases during processing following reboot.

The **EFI_OS_INDICATIONS_CAPSULE_RESULT_VAR_SUPPORTED** bit is set in *OsIndicationsSupported* variable if platform supports reporting of deferred capsule processing by creation of result variable as defined in [Section 7.5.6](#). This bit has no function if set in *OsIndications*.

The **EFI_OS_INDICATIONS_START_OS_RECOVERY** bit is set in the *OsIndicationsSupported* variable if the platform supports both the ability for an OS to indicate that OS-defined recovery should commence upon reboot, as well as support for the short-form File Path Media Device Path (see [Section 3.1.2](#)). If this bit is set in *OsIndications*, the platform firmware must bypass processing of the *BootOrder* variable during boot, and skip directly to OS-defined recovery (see [Section 3.4.1](#)) followed by Platform-defined recovery (see [Section 3.4.2](#)). System firmware must clear this bit in *OsIndications* when it starts OS-defined recovery.

The **EFI_OS_INDICATIONS_START_PLATFORM_RECOVERY** bit is set in the *OsIndicationsSupported* variable if the platform supports both the ability for an OS to indicate that Platform-defined recovery should commence upon reboot, as well as support for the short-form File Path Media Device Path (see [Section 3.1.2](#)). If this bit is set in *OsIndications*, the platform firmware must bypass processing of the *BootOrder* variable during boot, and skip directly to platform-defined recovery (see [Section 3.4.2](#)). System firmware must clear this bit in *OsIndications* when it starts Platform-defined recovery.

In all cases, if either of **EFI_OS_INDICATIONS_START_OS_RECOVERY** or **EFI_OS_INDICATIONS_START_PLATFORM_RECOVERY** is set in *OsIndicationsSupported*, both must be set and supported.

7.5.5 Delivery of Capsules via file on Mass Storage device

As an alternative to the `UpdateCapsule()` runtime API, capsules of any type supported by platform may also be delivered to firmware via a file within the EFI system partition on the mass storage device targeted for boot. Capsules staged using this method are processed on the next system restart. This method is only available when booting from mass storage devices which are formatted with GPT ([Section 5.3](#)) and contain an EFI System Partition in the device image. System firmware will search for capsule when

`EFI_OS_INDICATIONS_FILE_CAPSULE_DELIVERY_SUPPORTED` bit in `OsIndications` is set as described in [Section 7.5.4](#).

The directory `\EFI\UpdateCapsule` (letter case ignored) within the active EFI System Partition is defined for delivery of capsule to firmware. The binary structure of a capsule file on mass storage device is identical to the contents of capsule delivered via the EFI RunTime API except that fragmentation using `EFI_CAPSULE_BLOCK_DESCRIPTOR` is not supported and the single capsule must be stored in contiguous bytes within the file starting with `EFI_CAPSULE_HEADER`. The size of the file must equal `EFI_CAPSULE_HEADER.CapsuleImageSize` or error will be generated and the capsule ignored. Only a single capsule with a single `EFI_CAPSULE_HEADER` may be submitted within a file but more than one file each containing a capsule may be submitted during a single restart.

The file name of the capsule shall be chosen by submitter using 8-bit ASCII characters appropriate to the file system of the EFI system partition ([Section 12.3.1](#)). After examination and processing of a file placed in this directory the file will (if possible) be deleted by firmware. The deletion is performed in case of successful processing and also in the case of error but failure to successfully delete is not itself a reportable error.

More than one capsule file each containing a single capsule image may be stored in the specified directory. In case of multiple files, the system firmware shall process files in alphabetical order using

sort based on CHAR16 numerical value of file name characters, compared left to right. Lower case letter characters will be converted to upper case before compare. When comparing file names of unequal length, the space character shall be used to pad shorter file names. In case of file name containing one or more period characters (.), the right-most period, and the text to the right of the right-most period in the file name, will be removed before compare. In case of any file names with identical text after excluding any text after the right-most period, the order of processing shall be determined by sorting of any text found to right of the right-most period in file name string.

If a capsule processing is terminated by error any remaining additional capsule files will be processed normally.

The directory `\EFI\UpdateCapsule` is checked for capsules only within the EFI system partition on the device specified in the active boot option determine by reference to `BootNext` variable or `BootOrder` variable processing. The active Boot Variable is the variable with highest priority `BootNext` or within `BootOrder` that refers to a device found to be present. Boot variables in `BootOrder` but referring to devices not present are ignored when determining active boot variable.

The device to be checked for `\EFI\UpdateCapsule` is identified by reference to `FilePathList` field within the selected active `Boot####` variable. The system firmware is not required to check mass storage devices that do not contain boot target that is highest priority for boot nor to check a second EFI system partition not the target of the active boot variable.

In all cases that a capsule is identified for processing the system is restarted after capsule processing is completed. In case where `BootNext` variable was set, this variable is cleared when capsule processing is performed without actual boot of the variable indicated.

7.5.6 UEFI variable reporting on the Success or any Errors encountered in processing of capsules after restart

In cases where the processing of capsules is (1) delivered by call to `UpdateCapsule()` API but deferred to next restart, or (2) when capsules are delivered via mass storage device, a UEFI variable is created by firmware to indicate to capsule provider the status of the capsule processing. In the case were multiple capsules are delivered in calls to `UpdateCapsule()`, or multiple files on disk as described in [Section 7.5.5](#), or when a capsule contains multiple payloads as described in [Section 22.2](#), a separate result variable will be created for each capsule payload processed. The firmware will over-write result variables when calculated variable name already exists. However, to avoid unnecessarily consuming system variable store the result variable should be deleted by capsule provider after result status is examined.

UEFI variable reports will not be used when the entirety of capsule processing occurs within the call to `UpdateCapsule()` function.

The reporting variable attributes will be `EFI_VARIABLE_NON_VOLATILE + EFI_VARIABLE_BOOTSERVICE_ACCESS + EFI_VARIABLE_RUNTIME_ACCESS`.

The Vendor GUID of the reporting variable will be `EFI_CAPSULE_REPORT_GUID`. The name of the reporting variable will be `CapsuleNNNN` where `NNNN` is 4-digit hex number chosen by the firmware. The values of `NNNN` will be incremented by firmware starting at `Capsule0000` and continuing up to the platform-defined maximum.

The platform will publish the platform maximum in a read-only variable named **EFI_CAPSULE_REPORT_GUID:CapsuleMax**. The contents of *CapsuleMax* will be the string "CapsuleNNNN" where *NNNN* is the highest value used by platform before rolling over to *Capsule0000*. The platform will also publish the name of the last variable created in **EFI_CAPSULE_REPORT_GUID:CapsuleLast**.

When creating a new result variable, any previous variable with the same name will be overwritten. In case where variable storage is limited system firmware may optionally delete oldest report variables to create free space. If sufficient variable space cannot be freed the variable is not created.

Table 40. Variables Using EFI_CAPSULE_REPORT_GUID

Variable Name	Attributes	Internal Format
Capsule0000, Capsule0001, ... up to max	NV, BS, RT	EFI_CAPSULE_RESULT_VARIABLE
CapsuleMax	BS, RT, Read-Only	CHAR16[11] (no zero terminator)
CapsuleLast	NV, BS, RT, Read-Only	CHAR16[11] (no zero terminator)

EFI_CAPSULE_REPORT_GUID

```
// {39B68C46-F7FB-441B-B6EC-16B0F69821F3}
#define EFI_CAPSULE_REPORT_GUID \
    { 0x39b68c46, 0xf7fb, 0x441b, \
      {0xb6, 0xec, 0x16, 0xb0, 0xf6, 0x98, 0x21, 0xf3 } };
```

Structure of the Capsule Processing Result Variable

The Capsule Processing Result Variable contents always begin with the **EFI_CAPSULE_RESULT_VARIABLE_HEADER** structure. The value of *CapsuleGuid* determines any additional data that may follow within the instance of the Result Variable contents. For some values of *CapsuleGuid* no additional data may be defined.

As noted below, *VariableTotalSize* is the size of complete result variable including the entire header and any additional data required for particular *CapsuleGuid* types.

```
typedef struct {
    UINT32      VariableTotalSize;
    UINT32      Reserved; //for alignment
    EFI_GUID    CapsuleGuid;
    EFI_TIME    CapsuleProcessed;
    EFI_STATUS  CapsuleStatus;
} EFI_CAPSULE_RESULT_VARIABLE_HEADER;
```

VariableTotalSize

Size in bytes of the variable including any data beyond header as specified by *CapsuleGuid*.

CapsuleGuid

Guid from **EFI_CAPSULE_HEADER**

CapsuleProcessed

Timestamp using system time when processing completed.

CapsuleStatus

Result of the capsule processing. Exact interpretation of any error code may depend upon type of capsule processed.

Additional Structure When CapsuleGuid is EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID

The Capsule Processing Result Variable contents always begin with **EFI_CAPSULE_RESULT_VARIABLE_HEADER**. When *CapsuleGuid* is **EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID**, the header is followed by additional data as defined by **EFI_CAPSULE_RESULT_VARIABLE_FMP**.

```
typedef struct {
    UINT16      Version;
    UINT8      PayloadIndex;
    UINT8      UpdateImageIndex;

    EFI_GUID    UpdateImageTypeId;
    // CHAR16    CapsuleFileName[];
    // CHAR16    CapsuleTarget[];
} EFI_CAPSULE_RESULT_VARIABLE_FMP;
```

<i>Version</i>	The version of this structure, currently 0x00000001.
<i>PayloadIndex</i>	The index, starting from zero, of the payload within the FMP capsule which was processed to generate this report.
<i>UpdateImageIndex</i>	The <i>UpdateImageIndex</i> from EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER (after unsigned conversion from <code>UINT8</code> to <code>UINT16</code>).
<i>UpdateImageTypeId</i>	The <i>UpdateImageTypeId</i> Guid from EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER .
<i>CapsuleFileName</i>	In case of capsule loaded from disk, the zero-terminated array containing file name of capsule that was processed. In case of capsule submitted directly to UpdateCapsule() there is no file name, and this field is required to contain a single 16-bit zero character which is included in <i>VariableTotalSize</i> .
<i>CapsuleTarget</i>	This field will contain a zero-terminated CHAR16 string containing the text representation of the device path of device publishing Firmware Management Protocol (if present). In case where device path is not present and the target is not otherwise known to firmware, or when payload was blocked by policy, or

skipped, this field is required to contain a single 16-bit zero character which is included in *VariableTotalSize*.

Status Codes Returned in *CapsuleStatus*

EFI_SUCCESS	Valid capsule was passed and the capsule has been successfully processed by the firmware.
EFI_INVALID_PARAMETER	Invalid <i>CapsuleSize</i> , or an incompatible set of flags were set in the capsule header. In the case of a capsule file, the file size was not valid or an error was detected in the internal structure of the file.
EFI_DEVICE_ERROR	The capsule update was started, but failed due to a device error.
EFI_ACCESS_DENIED	Image within capsule was not loaded because the platform policy prohibits the image from being loaded.
EFI_LOAD_ERROR	For capsule with included driver, no driver with correct format for the platform was found.
EFI_UNSUPPORTED	The capsule type is not supported on this platform. Or the capsule internal structures were not recognized as valid by the platform.
EFI_OUT_OF_RESOURCES	There were insufficient resources to process the capsule.
EFI_NOT_READY	Capsule payload blocked by platform policy.
EFI_ABORTED	Capsule payload was skipped.

Protocols — EFI Loaded Image

This section defines **EFI_LOADED_IMAGE_PROTOCOL** and the **EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL**. Respectively, these protocols describe an Image that has been loaded into memory and specifies the device path used when a PE/COFF image was loaded through the EFI Boot Service **LoadImage ()**. These descriptions include the source from which the image was loaded, the current location of the image in memory, the type of memory allocated for the image, and the parameters passed to the image when it was invoked.

8.1 EFI Loaded Image Protocol

EFI_LOADED_IMAGE_PROTOCOL

Summary

Can be used on any image handle to obtain information about the loaded image.

GUID

```
#define EFI_LOADED_IMAGE_PROTOCOL_GUID\
    {0x5B1B31A1,0x9562,0x11d2,\
     {0x8E,0x3F,0x00,0xA0,0xC9,0x69,0x72,0x3B}}
```

Revision Number

```
#define EFI_LOADED_IMAGE_PROTOCOL_REVISION 0x1000
```

Protocol Interface Structure

```
typedef struct {
    UINT32                Revision;
    EFI_HANDLE            ParentHandle;
    EFI_SYSTEM_TABLE     *SystemTable;

    // Source location of the image
    EFI_HANDLE            DeviceHandle;
    EFI_DEVICE_PATH_PROTOCOL *FilePath;
    VOID                 *Reserved;

    // Image's load options
    UINT32                LoadOptionsSize;
    VOID                 *LoadOptions;

    // Location where image was loaded
    VOID                 *ImageBase;
    UINT64                ImageSize;
    EFI_MEMORY_TYPE       ImageCodeType;
    EFI_MEMORY_TYPE       ImageDataType;
    EFI_IMAGE_UNLOAD      Unload;
} EFI_LOADED_IMAGE_PROTOCOL;
```

Parameters

<i>Revision</i>	Defines the revision of the EFI_LOADED_IMAGE_PROTOCOL structure. All future revisions will be backward compatible to the current revision.
<i>ParentHandle</i>	Parent image's image handle. NULL if the image is loaded directly from the firmware's boot manager. Type EFI_HANDLE is defined in Section 6 .
<i>SystemTable</i>	The image's EFI system table pointer. Type EFI_SYSTEM_TABLE is defined in Section 4 .
<i>DeviceHandle</i>	The device handle that the EFI Image was loaded from. Type EFI_HANDLE is defined in Section 6 .
<i>FilePath</i>	A pointer to the file path portion specific to <i>DeviceHandle</i> that the EFI Image was loaded from. EFI_DEVICE_PATH_PROTOCOL is defined in Section 9.2 .

<i>Reserved</i>	Reserved. DO NOT USE.
<i>LoadOptionsSize</i>	The size in bytes of <i>LoadOptions</i> .
<i>LoadOptions</i>	A pointer to the image's binary load options.
<i>ImageBase</i>	The base address at which the image was loaded.
<i>ImageSize</i>	The size in bytes of the loaded image.
<i>ImageCodeType</i>	The memory type that the code sections were loaded as. Type EFI_MEMORY_TYPE is defined in Section 6 .
<i>ImageDataType</i>	The memory type that the data sections were loaded as. Type EFI_MEMORY_TYPE is defined in Section 6 .
<i>Unload</i>	Function that unloads the image. See Unload() .

Description

Each loaded image has an image handle that supports **EFI_LOADED_IMAGE_PROTOCOL**. When an image is started, it is passed the image handle for itself. The image can use the handle to obtain its relevant image data stored in the **EFI_LOADED_IMAGE_PROTOCOL** structure, such as its load options.

EFI_LOADED_IMAGE_PROTOCOL.Unload()

Summary

Unloads an image from memory.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_IMAGE_UNLOAD) (
    IN EFI_HANDLE    ImageHandle,
);
```

Parameters

ImageHandle The handle to the image to unload. Type [EFI_HANDLE](#) is defined in [Section](#).

Description

The **Unload()** function is a callback that a driver registers to do cleanup when the `UnloadImage` boot service function is called.

Status Codes Returned

EFI_SUCCESS	The image was unloaded.
EFI_INVALID_PARAMETER	The <i>ImageHandle</i> was not valid.

8.2 EFI Loaded Image Device Path Protocol

EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL

Summary

When installed, the Loaded Image Device Path Protocol specifies the device path that was used when a PE/COFF image was loaded through the EFI Boot Service **LoadImage()**.

GUID

```
#define EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL_GUID \
    {0xbc62157e, 0x3e33, 0x4fec, \
     {0x99, 0x20, 0x2d, 0x3b, 0x36, 0xd7, 0x50, 0xdf}}
```

Description

The Loaded Image Device Path Protocol uses the same protocol interface structure as the Device Path Protocol defined in Chapter 9. The only difference between the Device Path Protocol and the Loaded Image Device Path Protocol is the protocol GUID value.

The Loaded Image Device Path Protocol must be installed onto the image handle of a PE/COFF image loaded through the EFI Boot Service **LoadImage ()**. A copy of the device path specified by the *DevicePath* parameter to the EFI Boot Service **LoadImage ()** is made before it is installed onto the image handle. It is legal to call **LoadImage ()** for a buffer in memory with a **NULL** *DevicePath* parameter. In this case, the Loaded Image Device Path Protocol is installed with a **NULL** interface pointer.

Protocols — Device Path Protocol

This section contains the definition of the device path protocol and the information needed to construct and manage device paths in the UEFI environment. A device path is constructed and used by the firmware to convey the location of important devices, such as the boot device and console, consistent with the software-visible topology of the system.

9.1 Device Path Overview

A *Device Path* is used to define the programmatic path to a device. The primary purpose of a Device Path is to allow an application, such as an OS loader, to determine the physical device that the interfaces are abstracting.

A collection of device paths is usually referred to as a name space. ACPI, for example, is rooted around a name space that is written in ASL (ACPI Source Language). Given that EFI does not replace ACPI and defers to ACPI when ever possible, it would seem logical to utilize the ACPI name space in EFI. However, the ACPI name space was designed for usage at operating system runtime and does not fit well in platform firmware or OS loaders. Given this, EFI defines its own name space, called a *Device Path*.

A Device Path is designed to make maximum leverage of the ACPI name space. One of the key structures in the Device Path defines the linkage back to the ACPI name space. The Device Path also is used to fill in the gaps where ACPI defers to buses with standard enumeration algorithms. The Device Path is able to relate information about which device is being used on buses with standard enumeration mechanisms. The Device Path is also used to define the location on a medium where a file should be, or where it was loaded from. A special case of the Device Path can also be used to support the optional booting of legacy operating systems from legacy media.

The Device Path was designed so that the OS loader and the operating system could tell which devices the platform firmware was using as boot devices. This allows the operating system to maintain a view of the system that is consistent with the platform firmware. An example of this is a “headless” system that is using a network connection as the boot device and console. In such a case, the firmware will convey to the operating system the network adapter and network protocol information being used as the console and boot device in the device path for these devices.

9.2 EFI Device Path Protocol

This section provides a detailed description of **EFI_DEVICE_PATH_PROTOCOL**.

EFI_DEVICE_PATH_PROTOCOL

Summary

Can be used on any device handle to obtain generic path/location information concerning the physical device or logical device. If the handle does not logically map to a physical device, the

handle may not necessarily support the device path protocol. The device path describes the location of the device the handle is for. The size of the Device Path can be determined from the structures that make up the Device Path.

GUID

```
#define EFI_DEVICE_PATH_PROTOCOL_GUID \
    {0x09576e91,0x6d3f,0x11d2,\
     {0x8e,0x39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Protocol Interface Structure

```
/**
 *
 */
// EFI_DEVICE_PATH_PROTOCOL
/**
 *
 */
typedef struct _EFI_DEVICE_PATH_PROTOCOL {
    UINT8  Type;
    UINT8  SubType;
    UINT8  Length[2];
} EFI_DEVICE_PATH_PROTOCOL;
```

Description

The executing UEFI Image may use the device path to match its own device drivers to the particular device. Note that the executing UEFI OS loader and UEFI application images must access all physical devices via Boot Services device handles until [EFI_BOOT_SERVICES.ExitBootServices\(\)](#) is successfully called. A UEFI driver may access only a physical device for which it provides functionality.

9.3 Device Path Nodes

There are six major types of Device Path nodes:

- **Hardware Device Path.** This Device Path defines how a device is attached to the resource domain of a system, where resource domain is simply the shared memory, memory mapped I/O, and I/O space of the system.
- **ACPI Device Path.** This Device Path is used to describe devices whose enumeration is not described in an industry-standard fashion. These devices must be described using ACPI AML in the ACPI name space; this Device Path is a linkage to the ACPI name space.
- **Messaging Device Path.** This Device Path is used to describe the connection of devices outside the resource domain of the system. This Device Path can describe physical messaging information such as a SCSI ID, or abstract information such as networking protocol IP addresses.
- **Media Device Path.** This Device Path is used to describe the portion of a medium that is being abstracted by a boot service. For example, a Media Device Path could define which partition on a hard drive was being used.

- BIOS Boot Specification Device Path. This Device Path is used to point to boot legacy operating systems; it is based on the BIOS Boot Specification Version 1.01. Refer to [Appendix Q](#) for details on obtaining this specification.
- End of Hardware Device Path. Depending on the Sub-Type, this Device Path node is used to indicate the end of the Device Path instance or Device Path structure.

9.3.1 Generic Device Path Structures

A Device Path is a variable-length binary structure that is made up of variable-length generic Device Path nodes. [Table 41](#) defines the structure of a variable-length generic Device Path node and the lengths of its components. The table defines the type and sub-type values corresponding to the Device Paths described in [Section 9.3](#); all other type and sub-type values are *Reserved*.

Table 41. Generic Device Path Node Structure

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 0x01 – Hardware Device Path Type 0x02 – ACPI Device Path Type 0x03 – Messaging Device Path Type 0x04 – Media Device Path Type 0x05 – BIOS Boot Specification Device Path Type 0x7F – End of Hardware Device Path
Sub-Type	1	1	Sub-Type – Varies by Type. (See Table 42 .)
Length	2	2	Length of this structure in bytes. Length is 4 + n bytes.
Specific Device Path Data	4	n	Specific Device Path data. Type and Sub-Type define type of data. Size of data is included in Length.

A Device Path is a series of generic Device Path nodes. The first Device Path node starts at byte offset zero of the Device Path. The next Device Path node starts at the end of the previous Device Path node. Therefore all nodes are byte-packed data structures that may appear on any byte boundary. All code references to device path notes must assume all fields are unaligned. Since every Device Path node contains a length field in a known place, it is possible to traverse Device Path nodes that are of an unknown type. There is no limit to the number, type, or sequence of nodes in a Device Path.

A Device Path is terminated by an End of Hardware Device Path node. This type of node has two sub-types (see [Table 42](#)):

- *End This Instance of a Device Path* (sub-type 0x01). This type of node terminates one Device Path instance and denotes the start of another. This is only required when an environment variable represents multiple devices. An example of this would be the **ConsoleOut** environment variable that consists of both a VGA console and serial output console. This variable would describe a console output stream that is sent to both VGA and serial concurrently and thus has a Device Path that contains two complete Device Paths.
- *End Entire Device Path* (sub-type 0xFF). This type of node terminates an entire Device Path. Software searches for this sub-type to find the end of a Device Path. All Device Paths must end with this sub-type.

Table 42. Device Path End Structure

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 0x7F – End of Hardware Device Path
Sub-Type	1	1	Sub-Type 0xFF – End Entire Device Path, or Sub-Type 0x01 – End This Instance of a Device Path and start a new Device Path
Length	2	2	Length of this structure in bytes. Length is 4 bytes.

9.3.2 Hardware Device Path

This Device Path defines how a device is attached to the resource domain of a system, where resource domain is simply the shared memory, memory mapped I/O, and I/O space of the system. It is possible to have multiple levels of Hardware Device Path such as a PCCARD device that was attached to a PCCARD PCI controller.

9.3.2.1 PCI Device Path

The Device Path for PCI defines the path to the PCI configuration space address for a PCI device. There is one PCI Device Path entry for each device and function number that defines the path from the root PCI bus to the device. Because the PCI bus number of a device may potentially change, a flat encoding of single PCI Device Path entry cannot be used. An example of this is when a PCI device is behind a bridge, and one of the following events occurs:

- OS performs a Plug and Play configuration of the PCI bus.
- A hot plug of a PCI device is performed.
- The system configuration changes between reboots.

The PCI Device Path entry must be preceded by an ACPI Device Path entry that uniquely identifies the PCI root bus. The programming of root PCI bridges is not defined by any PCI specification and this is why an ACPI Device Path entry is required.

Table 43. PCI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 – Hardware Device Path
Sub-Type	1	1	Sub-Type 1 – PCI
Length	2	2	Length of this structure is 6 bytes
Function	4	1	PCI Function Number
Device	5	1	PCI Device Number

9.3.2.2 PCCARD Device Path

Table 44. PCCARD Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 – Hardware Device Path
Sub-Type	1	1	Sub-Type 2 – PCCARD
Length	2	2	Length of this structure in bytes. Length is 5 bytes.
Function Number	4	1	Function Number (0 = First Function)

9.3.2.3 Memory Mapped Device Path

Table 45. Memory Mapped Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 – Hardware Device Path.
Sub-Type	1	1	Sub-Type 3 – Memory Mapped.
Length	2	2	Length of this structure in bytes. Length is 24 bytes.
Memory Type	4	4	EFI_MEMORY_TYPE . Type EFI_MEMORY_TYPE is defined in the EFI_BOOT_SERVICES.AllocatePages() function description.
Start Address	8	8	Starting Memory Address.
End Address	16	8	Ending Memory Address.

9.3.2.4 Vendor Device Path

The Vendor Device Path allows the creation of vendor-defined Device Paths. A vendor must allocate a Vendor GUID for a Device Path. The Vendor GUID can then be used to define the contents on the *n* bytes that follow in the Vendor Device Path node.

Table 46. Vendor-Defined Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 – Hardware Device Path.
Sub-Type	1	1	Sub-Type 4 – Vendor.
Length	2	2	Length of this structure in bytes. Length is 20 + <i>n</i> bytes.
Vendor_GUID	4	16	Vendor-assigned GUID that defines the data that follows.
Vendor Defined Data	20	<i>n</i>	Vendor-defined variable size data.

9.3.2.5 Controller Device Path

Table 47. Controller Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 – Hardware Device Path.
Sub-Type	1	1	Sub-Type 5 – Controller.
Length	2	2	Length of this structure in bytes. Length is 8 bytes.
Controller Number	4	4	Controller number.

9.3.2.6 BMC Device Path

The Device Path for a Baseboard Management Controller (BMC) host interface.

Table 48. BMC Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 – Hardware Device Path.
Sub-Type	1	1	Sub Type 6 – BMC
Length	2	2	Length of this structure in bytes. Length is 13 bytes.
Interface Type	4	1	The Baseboard Management Controller (BMC) host interface type: 0x00: Unknown 0x01: KCS: Keyboard Controller Style 0x02: SMIC: Server Management Interface Chip 0x03: BT: Block Transfer
Base Address	5	8	Base address (either memory-mapped or I/O) of the BMC. If the least-significant bit of the field is a 1, the address is in I/O space; otherwise, the address is memory-mapped. Refer to the IPMI Interface Specification for usage details.

9.3.3 ACPI Device Path

This Device Path contains ACPI Device IDs that represent a device’s Plug and Play Hardware ID and its corresponding unique persistent ID. The ACPI IDs are stored in the ACPI _HID, _CID, and _UID device identification objects that are associated with a device. The ACPI Device Path contains values that must match exactly the ACPI name space that is provided by the platform firmware to the operating system. Refer to the ACPI specification for a complete description of the _HID, _CID, and _UID device identification objects.

The _HID and _CID values are optional device identification objects that appear in the ACPI name space. If only _HID is present, the _HID must be used to describe any device that will be enumerated by the ACPI driver. The _CID, if present, contains information that is important for the OS to attach generic driver (e.g., PCI Bus Driver), while the _HID contains information important for the OS to attach device-specific driver. The ACPI bus driver only enumerates a device when no standard bus enumerator exists for a device.

The `_UID` object provides the OS with a serial number-style ID for a device that does not change across reboots. The object is optional, but is required when a system contains two devices that report the same `_HID`. The `_UID` only needs to be unique among all device objects with the same `_HID` value. If no `_UID` exists in the APCI name space for a `_HID` the value of zero must be stored in the `_UID` field of the ACPI Device Path.

The ACPI Device Path is only used to describe devices that are not defined by a Hardware Device Path. An `_HID` (along with `_CID` if present) is required to represent a PCI root bridge, since the PCI specification does not define the programming model for a PCI root bridge. There are two subtypes of the ACPI Device Path: a simple subtype that only includes the `_HID` and `_UID` fields, and an extended subtype that includes the `_HID`, `_CID`, and `_UID` fields.

The ACPI Device Path node only supports numeric 32-bit values for the `_HID` and `_UID` values. The Expanded ACPI Device Path node supports both numeric and string values for the `_HID`, `_UID`, and `_CID` values. As a result, the ACPI Device Path node is smaller and should be used if possible to reduce the size of device paths that may potentially be stored in nonvolatile storage. If a string value is required for the `_HID` field, or a string value is required for the `_UID` field, or a `_CID` field is required, then the Expanded ACPI Device Path node must be used. If a string field of the Expanded ACPI Device Path node is present, then the corresponding numeric field is ignored.

The `_HID` and `_CID` fields in the ACPI Device Path node and Expanded ACPI Device Path node are stored as a 32-bit compressed EISA-type IDs. The following macro can be used to compute these EISA-type IDs from a Plug and Play Hardware ID. The Plug and Play Hardware IDs used to compute the `_HID` and `_CID` fields in the EFI device path nodes must match the Plug and Play Hardware IDs used to build the matching entries in the ACPI tables. The compressed EISA-type IDs produced by this macro differ from the compressed EISA-type IDs stored in ACPI tables. As a result, the compressed EISA-type IDs from the ACPI Device Path nodes cannot be directly compared to the compressed EISA-type IDs from the ACPI table.

```
#define EFI_PNP_ID(ID) (UINT32)((ID) << 16 | 0x41D0)
#define EISA_PNP_ID(ID) EFI_PNP_ID(ID)
```

Table 49. ACPI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 2 – ACPI Device Path.
Sub-Type	1	1	Sub-Type 1 ACPI Device Path.
Length	2	2	Length of this structure in bytes. Length is 12 bytes.
<code>_HID</code>	4	4	Device’s PnP hardware ID stored in a numeric 32-bit compressed EISA-type ID. This value must match the corresponding <code>_HID</code> in the ACPI name space.
<code>_UID</code>	8	4	Unique ID that is required by ACPI if two devices have the same <code>_HID</code> . This value must also match the corresponding <code>_UID/_HID</code> pair in the ACPI name space. Only the 32-bit numeric value type of <code>_UID</code> is supported; thus strings must not be used for the <code>_UID</code> in the ACPI name space.

Table 50. Expanded ACPI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 2 – ACPI Device Path.
Sub-Type	1	1	Sub-Type 2 Expanded ACPI Device Path.
Length	2	2	Length of this structure in bytes. Minimum length is 19 bytes. The actual size will depend on the size of the _HIDSTR, _UIDSTR, and _CIDSTR fields.
_HID	4	4	Device’s PnP hardware ID stored in a numeric 32-bit compressed EISA-type ID. This value must match the corresponding _HID in the ACPI name space.
_UID	8	4	Unique ID that is required by ACPI if two devices have the same _HID. This value must also match the corresponding _UID/_HID pair in the ACPI name space.
_CID	12	4	Device’s compatible PnP hardware ID stored in a numeric 32-bit compressed EISA-type ID. This value must match at least one of the compatible device IDs returned by the corresponding _CID in the ACPI name space.
_HIDSTR	16	>=1	Device’s PnP hardware ID stored as a null-terminated ASCII string. This value must match the corresponding _HID in the ACPI name space. If the length of this string not including the null-terminator is 0, then the _HID field is used. If the length of this null-terminated string is greater than 0, then this field supersedes the _HID field.
_UIDSTR	Varies	>=1	Unique ID that is required by ACPI if two devices have the same _HID. This value must also match the corresponding _UID/_HID pair in the ACPI name space. This value is stored as a null-terminated ASCII string. If the length of this string not including the null-terminator is 0, then the _UID field is used. If the length of this null-terminated string is greater than 0, then this field supersedes the _UID field. The Byte Offset of this field can be computed by adding 16 to the size of the _HIDSTR field.
_CIDSTR	Varies	>=1	Device’s compatible PnP hardware ID stored as a null-terminated ASCII string. This value must match at least one of the compatible device IDs returned by the corresponding _CID in the ACPI name space. If the length of this string not including the null-terminator is 0, then the _CID field is used. If the length of this null-terminated string is greater than 0, then this field supersedes the _CID field. The Byte Offset of this field can be computed by adding 16 to the sum of the sizes of the _HIDSTR and _UIDSTR fields.

9.3.4 ACPI _ADR Device Path

The _ADR device path is used to contain video output device attributes to support the Graphics Output Protocol. The device path can contain multiple _ADR entries if multiple video output devices are displaying the same output.

Table 51. ACPI _ADR Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 2 – ACPI Device Path
Sub-Type	1	1	Sub-Type3 _ADR Device Path
Length	2	2	Length of this structure in bytes. Minimum length is 8.
_ADR	4	4	_ADR value. For video output devices the value of this field comes from Table B-2 ACPI 3.0 specification. At least one _ADR value is required
Additional _ADR	8	N	This device path may optionally contain more than one _ADR entry.

9.3.5 Messaging Device Path

This Device Path is used to describe the connection of devices outside the resource domain of the system. This Device Path can describe physical messaging information like SCSI ID, or abstract information like networking protocol IP addresses.

9.3.5.1 ATAPI Device Path

Table 52. ATAPI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 1 – ATAPI
Length	2	2	Length of this structure in bytes. Length is 8 bytes.
PrimarySecondary	4	1	Set to zero for primary or one for secondary
SlaveMaster	5	1	Set to zero for master or one for slave mode
Logical Unit Number	6	2	Logical Unit Number

9.3.5.2 SCSI Device Path

Table 53. SCSI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 2 – SCSI
Length	2	2	Length of this structure in bytes. Length is 8 bytes.
Target ID	4	2	Target ID on the SCSI bus (PUN)

Logical Unit Number	6	2	Logical Unit Number (LUN)
---------------------	---	---	----------------------------

9.3.5.3 Fibre Channel Device Path

Table 54. Fibre Channel Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 3 – Fibre Channel
Length	2	2	Length of this structure in bytes. Length is 24 bytes.
Reserved	4	4	Reserved
World Wide Name	8	8	Fibre Channel World Wide Name
Logical Unit Number	16	8	Fibre Channel Logical Unit Number

Table 55. Fibre Channel Ex Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 21 – Fibre Channel Ex
Length	2	2	Length of this structure in bytes. Length is 24 bytes.
Reserved	4	4	Reserved
World Wide Name	8	8	8 byte array containing Fibre Channel End Device Port Name (a.k.a., World Wide Name)
Logical Unit Number	16	8	8 byte array containing Fibre Channel Logical Unit Number

The Fibre Channel Ex device path clarifies the definition of the Logical Unit Number field to conform with the T-10 SCSI Architecture Model 4 specification. The 8 byte Logical Unit Number field in the device path must conform with a logical unit number returned by a SCSI REPORT LUNS command.

When the Fibre Channel Ex Device Path is used with the Extended SCSI Pass Thru Protocol the UINT64 LUN argument must be converted to the eight byte array Logical Unit Number field in the device path by treating the eight byte array as an EFI UINT64. For example a Logical Unit Number array of { 0,1,2,3,4,5,6,7 } becomes a UINT64 of 0x0706050403020100.

When an application client displays or otherwise makes a 64-bit LUN visible to a user, it should be done in conformance with SAM-4. SAM-4 requires a LUN to be displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e., on the right) regardless of the internal representation of the LUN. UEFI defines all data structures a “little endian” and SCSI defines all data structures as “big endian”. Fibre Channel Ex Device Path Example shows an example device path for a Fibre Channel controller on a typical UEFI platform. This Fibre Channel Controller is connected to the port 0 of the root hub, and its interface number is 0. The Fibre Channel Host

Controller is a PCI device whose PCI device number 0x1F and PCI function 0x00. So, the whole device path for this Fibre Channel Controller consists an ACPI Device Path Node, a PCI Device Path Node, a Fibre Channel Device Path Node and a Device Path End Structure. The `_HID` and `_UID` must match the ACPI table description of the PCI Root Bridge. The Fibre Channel WWN and LUN were picked to show byte order and they are not typical real world values. The shorthand notation for this device path is:

PciRoot(0)/PCI(31,0)/FibreEx(0x0001020304050607, 0x0001020304050607)

Table 56. Fibre Channel Ex Device Path Example

Byte Offset	Byte Length	Data	Description
0	1	0x02	Generic Device Path Header – Type ACPI Device Path
1	1	0x01	Sub type – ACPI Device Path
2	2	0x0C	Length – 0x0C bytes
4	4	0x41D0, 0x0A03	<code>_HID</code> PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
8	4	0x0000	<code>_UID</code>
12	1	0x01	Generic Device Path Header – Type Hardware Device Path
13	1	0x01	Sub type – PCI
14	2	0x06	Length – 0x06 bytes
16	1	0x0	PCI Function
17	1	0x1F	PCI Device
18	1	0x03	Generic Device Path Header – Type Message Device Path
19	1	0x15	Sub type – Fibre Channel Ex
20	2	0x14	Length – 20 bytes
21	1	0x00	8 byte array containing Fibre Channel End Device Port Name (a.k.a., World Wide Name)
22	1	0x01	
23	1	0x02	
24	1	0x03	
25	1	0x04	
26	1	0x05	
27	1	0x06	
28	1	0x07	
29	1	0x00	8 byte array containing Fibre Channel Logical Unit Number
30	1	0x01	
31	1	0x02	
32	1	0x03	
33	1	0x04	
34	1	0x05	
35	1	0x06	

36	1	0x07	
37	1	0xFF	Generic Device Path Header – Type End of Hardware Device Path
38	1	0xFF	Sub type – End of Entire Device Path
39	2	0x04	Length – 0x04 bytes

9.3.5.4 1394 Device Path

Table 57. 1394 Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 4 – 1394
Length	2	2	Length of this structure in bytes. Length is 16 bytes.
Reserved	4	4	Reserved
GUID ¹	8	8	1394 Global Unique ID (GUID) ¹

Note: ¹ The usage of the term GUID is per the 1394 specification. This is not the same as the **EFI_GUID** type defined in the EFI Specification.

9.3.5.5 USB Device Paths

Table 58. USB Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 5 – USB
Length	2	2	Length of this structure in bytes. Length is 6 bytes.
USB Parent Port Number	4	1	USB Parent Port Number
Interface	5	1	USB Interface Number

9.3.5.5.1 USB Device Path Example

[Table 59](#) shows an example device path for a USB controller on a desktop platform. This USB Controller is connected to the port 0 of the root hub, and its interface number is 0. The USB Host Controller is a PCI device whose PCI device number 0x1F and PCI function 0x02. So, the whole device path for this USB Controller consists an ACPI Device Path Node, a PCI Device Path Node, a USB Device Path Node and a Device Path End Structure. The `_HID` and `_UID` must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

PciRoot(0)/PCI(31,2)/USB(0,0).

Table 59. USB Device Path Examples

Byte Offset	Byte Length	Data	Description
-------------	-------------	------	-------------

0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x02	PCI Function
0x11	0x01	0x1F	PCI Device
0x12	0x01	0x03	Generic Device Path Header – Type Message Device Path
0x13	0x01	0x05	Sub type – USB
0x14	0x02	0x06	Length – 0x06 bytes
0x16	0x01	0x00	Parent Hub Port Number
0x17	0x01	0x00	Controller Interface Number
0x18	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x19	0x01	0xFF	Sub type – End of Entire Device Path
0x1A	0x02	0x04	Length – 0x04 bytes

Another example is a USB Controller (interface number 0) that is connected to port 3 of a USB Hub Controller (interface number 0), and this USB Hub Controller is connected to the port 1 of the root hub. The shorthand notation for this device path is:

PciRoot(0)/PCI(31,2)/USB(1,0)/USB(3,0).

[Table 59](#) shows the device path for this USB Controller.

Table 60. Another USB Device Path Example

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x02	PCI Function

Byte Offset	Byte Length	Data	Description
0x11	0x01	0x1F	PCI Device
0x12	0x01	0x03	Generic Device Path Header – Type Message Device Path
0x13	0x01	0x05	Sub type – USB
0x14	0x02	0x06	Length – 0x06 bytes
0x16	0x01	0x01	Parent Hub Port Number
0x17	0x01	0x00	Controller Interface Number
0x18	0x01	0x03	Generic Device Path Header – Type Message Device Path
0x19	0x01	0x05	Sub type – USB
0x1A	0x02	0x06	Length – 0x06 bytes
0x1C	0x01	0x03	Parent Hub Port Number
0x1D	0x01	0x00	Controller Interface Number
0x1E	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x1F	0x01	0xFF	Sub type – End of Entire Device Path
0x20	0x02	0x04	Length – 0x04 bytes

9.3.5.6 SATA Device Path

Table 61. SATA Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 18 – SATA
Length	2	2	Length of this structure in bytes. Length is 10 bytes.
HBA Port Number	4	2	The HBA port number that facilitates the connection to the device or a port multiplier. The value 0xFFFF is reserved.
Port Multiplier Port Number	6	2	The Port multiplier port number that facilitates the connection to the device. Must be set to 0xFFFF if the device is directly connected to the HBA.
Logical Unit Number	8	2	Logical Unit Number.

9.3.5.7 USB Device Paths (WWID)

This device path describes a USB device using its serial number.

Specifications, such as the USB Mass Storage class, bulk-only transport subclass, require that some portion of the suffix of the device’s serial number be unique with respect to the vendor and product id for the device. So, in order to avoid confusion and overlap of WWID’s, the interface’s class, subclass, and protocol are included.

Table 62. USB WWID Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 16– USB WWID
Length	2	2	Length of this structure in bytes. Length is 10+
• Interface Number	4	2	USB interface number
• Device Vendor Id	6	2	USB vendor id of the device
• Device Product Id	8	2	USB product id of the device
• Serial Number	10	n	Last 64-or-fewer UTF-16 characters of the USB serial number. The length of the string is determined by the <i>Length</i> field less the offset of the <i>Serial Number</i> field (10)

Devices that do not have a serial number string must use with the USB Device Path (type 5) as described in [Section 9.3.5.5](#).

Including the interface as part of this node allows distinction for multi-interface devices, e.g., an HID interface and a Mass Storage interface on the same device, or two Mass Storage interfaces.

[Section 3.1.2](#) defines special rules for processing the USB WWID Device Path. These special rules enable a device location to change and still have the system boot from the device.

9.3.5.8 Device Logical Unit

For some classes of devices, such as USB Mass Storage, it is necessary to specify the Logical Unit Number (LUN), since a single device may have multiple logical units. In order to boot from one of these logical units of the device, the Device Logical Unit device node is appended to the device path. The EFI path node subtype is defined, as in [Table 63](#).

Table 63. Device Logical Unit

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 17 – Device Logical unit
Length	2	2	Length of this structure in bytes. Length is 5
LUN	4	1	Logical Unit Number for the interface

[Section 3.1.2](#) defines special rules for processing the USB Class Device Path. These special rules enable a device location to change and still have the system recognize the device.

[Section 3.3](#) defines how the *ConIn*, *ConOut*, and *ErrOut* variables are processed and contains special rules for processing the USB Class device path. These special rules allow all USB keyboards to be specified as valid input devices.

9.3.5.9 USB Device Path (Class)

Table 64. USB Class Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path.
Sub-Type	1	1	Sub-Type 15 - USB Class.
Length	2	2	Length of this structure in bytes. Length is 11 bytes.
Vendor ID	4	2	Vendor ID assigned by USB-IF. A value of 0xFFFF will match any Vendor ID.
Product ID	6	2	Product ID assigned by USB-IF. A value of 0xFFFF will match any Product ID.
Device Class	8	1	The class code assigned by the USB-IF. A value of 0xFF will match any class code.
Device Subclass	9	1	The subclass code assigned by the USB-IF. A value of 0xFF will match any subclass code.
Device Protocol	10	1	The protocol code assigned by the USB-IF. A value of 0xFF will match any protocol code.

9.3.5.10 I₂O Device Path

Table 65. I₂O Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 6 – I2O Random Block Storage Class
Length	2	2	Length of this structure in bytes. Length is 8 bytes.
TID	4	4	Target ID (TID) for a device

9.3.5.11 MAC Address Device Path

Table 66. MAC Address Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 11 – MAC Address for a network interface
Length	2	2	Length of this structure in bytes. Length is 37 bytes.
MAC Address	4	32	The MAC address for a network interface padded with 0s
IfType	36	1	Network interface type(i.e., 802.3, FDDI). See RFC 3232

9.3.5.12 IPv4 Device Path

Previous versions of the specification only defined a 19 byte IPv4 device path. To access fields at off-set 19 or greater, the size of the device path must be checked first.

Table 67. IPv4 Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 12 – IPv4
Length	2	2	Length of this structure in bytes. Length is 27 bytes.
Local IP Address	4	4	The local IPv4 address
Remote IP Address	8	4	The remote IPv4 address
Local Port	12	2	The local port number
Remote Port	14	2	The remote port number
Protocol	16	2	The network protocol(i.e., UDP, TCP). See RFC 3232
StaticIPAddress	18	1	0x00 - The Source IP Address was assigned though DHCP 0x01 - The Source IP Address is statically bound
GatewayIPAddress	19	4	The Gateway IP Address
Subnet Mask	23	4	Subnet mask

9.3.5.13 IPv6 Device Path

Table 68. IPv6 Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 13 – IPv6
Length	2	2	Length of this structure in bytes. Length is 60 bytes.
Local IP Address	4	16	The local IPv6 address
Remote IP Address	20	16	The remote IPv6 address
Local Port	36	2	The local port number
Remote Port	38	2	The remote port number
Protocol	40	2	The network protocol (i.e., UDP, TCP). See RFC 3232
IPAddressOrigin	42	1	0x00 - The Local IP Address was manually configured. 0x01 - The Local IP Address is assigned through IPv6 stateless auto-configuration. 0x02 - The Local IP Address is assigned through IPv6stateful configuration.
PrefixLength	43	1	The Prefix Length
GatewayIPAddress	44	16	The Gateway IP Address

9.3.5.14 2.VLAN device path node

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 20 – Vlan (802.1q)
Length	2	2	Length of this device node
VlanId	4	2	VLAN identifier (0-4094)

9.3.5.15 InfiniBand Device Path

Table 69. InfiniBand Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 9 – InfiniBand
Length	2	2	Length of this structure in bytes. Length is 48 bytes.
Resource Flags	4	4	Flags to help identify/manage InfiniBand device path elements: <ul style="list-style-type: none"> • Bit 0 – IOC/Service (0b = IOC, 1b = Service) • Bit 1 – Extend Boot Environment • Bit 2 – Console Protocol • Bit 3 – Storage Protocol • Bit 4 – Network Protocol All other bits are reserved.
PORT GUID	8	16	128-bit Global Identifier for remote fabric port
IOC GUID/Service ID	24	8	64-bit unique identifier to remote IOC or server process. Interpretation of field specified by Resource Flags (bit 0)
Target Port ID	32	8	64-bit persistent ID of remote IOC port
Device ID	40	8	64-bit persistent ID of remote device
Note: The usage of the terms GUID and GID is per the InfiniBand Specification. The term GUID is not the same as the EFI_GUID type defined in this EFI Specification.			

9.3.5.16 UART Device Path

Table 70. UART Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 14 – UART
Length	2	2	Length of this structure in bytes. Length is 19 bytes.
Reserved	4	4	Reserved

Baud Rate	8	8	The baud rate setting for the UART style device. A value of 0 means that the device's default baud rate will be used.
Data Bits	16	1	The number of data bits for the UART style device. A value of 0 means that the device's default number of data bits will be used.
Parity	17	1	The parity setting for the UART style device. Parity 0x00 - Default Parity Parity 0x01 - No Parity Parity 0x02 - Even Parity Parity 0x03 - Odd Parity Parity 0x04 - Mark Parity Parity 0x05 - Space Parity
Stop Bits	18	1	The number of stop bits for the UART style device. Stop Bits 0x00 - Default Stop Bits Stop Bits 0x01 - 1 Stop Bit Stop Bits 0x02 - 1.5 Stop Bits Stop Bits 0x03 - 2 Stop Bits

9.3.5.17 Vendor-Defined Messaging Device Path

Table 71. Vendor-Defined Messaging Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 10 – Vendor
Length	2	2	Length of this structure in bytes. Length is 20 + <i>n</i> bytes.
Vendor GUID	4	16	Vendor-assigned GUID that defines the data that follows
Vendor Defined Data	20	<i>n</i>	Vendor-defined variable size data

The following GUIDs are used with a Vendor-Defined Messaging Device Path to describe the transport protocol for use with PC-ANSI, VT-100, VT-100+, and VT-UTF8 terminals. Device paths can be constructed with this node as the last node in the device path. The rest of the device path describes the physical device that is being used to transmit and receive data. The PC-ANSI, VT-100, VT-100+, and VT-UTF8 GUIDs define the format of the data that is being sent though the physical device. Additional GUIDs can be generated to describe additional transport protocols.

```
#define EFI_PC_ANSI_GUID \
    { 0xe0c14753, 0xf9be, 0x11d2, {0x9a, 0x0c, 0x00, 0x90, 0x27, 0x3f, 0xc1, 0x4d } }

#define EFI_VT_100_GUID \
    { 0xdfa66065, 0xb419, 0x11d3, {0x9a, 0x2d, 0x00, 0x90, 0x27, 0x3f, 0xc1, 0x4d } }

#define EFI_VT_100_PLUS_GUID \
    { 0x7baec70b, 0x57e0, 0x4c76, {0x8e, 0x87, 0x2f, 0x9e, 0x28, 0x08, 0x83, 0x43 } }
```

```
#define EFI_VT_UTF8_GUID \
    { 0xad15a0d6, 0x8bec, 0x4acf, {0xa0, 0x73, 0xd0, 0x1d, 0xe7, 0x7e, 0x2d, 0x88 } }
```

9.3.5.18 UART Flow Control Messaging Path

The UART messaging device path defined in the EFI 1.02 specification does not contain a provision for flow control. Therefore, a new device path node is needed to declare flow control characteristics. It is a vendor-defined messaging node which may be appended to the UART node in a device path. It has the following definition:

```
#define DEVICE_PATH_MESSAGING_UART_FLOW_CONTROL \
    {0x37499a9d, 0x542f, 0x4c89, {0xa0, 0x26, 0x35, 0xda, 0x14, 0x20, 0x94, 0xe4} }
```

Table 72. UART Flow Control Messaging Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 10 – Vendor
Length	2	2	Length of this structure in bytes. Length is 24 bytes.
Vendor GUID	4	16	DEVICE_PATH_MESSAGING_UART_FLOW_CONTROL
Flow_Control_Map	20	4	Bitmap of supported flow control types. <ul style="list-style-type: none"> • Bit 0 set indicates hardware flow control. • Bit 1 set indicates Xon/Xoff flow control. • All other bits are reserved and are clear.

A debugport driver that implements Xon/Xoff flow control would produce a device path similar to the following:

```
PciRoot(0)/Pci(0x1f,0)/ACPI(PNP0501,0)/UART(115200,N,8,1)/
UartFlowCtrl(2)/DebugPort()
```

Note: *If no bits are set in the Flow_Control_Map, this indicates there is no flow control and is equivalent to leaving the flow control node out of the device path completely.*

9.3.5.19 Serial Attached SCSI (SAS) Device Path

This section defines the device node for Serial Attached SCSI (SAS) devices.

Table 73. Messaging Device Path Structure

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type -3 Messaging
Sub Type	1	1	10 (Vendor)
Length	2	2	Length of this Structure.
Vendor GUID	4	16	d487ddb4-008b-11d9-afdc-001083ffca4d
Reserved	20	4	Reserved for future use.
SAS Address	24	8	SAS Address for Serial Attached SCSI Target.

Logical Unit Number	32	8	SAS Logical Unit Number.
SAS/SATA device and Topology Info	40	2	More Information about the device and its interconnect
Relative Target Port	42	2	Relative Target Port (RTP)

Summary

The device node represented by the structure in [Table 73](#) (above) shall be appended after the Hardware Device Path node in the device path.

There are two cases for boot devices connected with SAS HBA's. Each of the cases is described below with an example of the expected Device Path for these.

- SAS Device anywhere in an SAS domain accessed through SSP Protocol.
PciRoot (0) / PCI (1, 0) / Sas (0x31000004CF13F6BD, 0)
 The first 64-bit number represents the SAS address of the target SAS device.
 The second number is the boot LUN of the target SAS device.
 The third number is the Relative Target Port (RTP)
- SATA Device connected directly to a HBA port.
PciRoot (0) / PCI (1, 0) / Sas (0x31000004CF13F6BD)
 The first number represents either a real SAS address reserved by the HBA for above connections, or a fake but unique SAS address generated by the HBA to represent the SATA device.

9.3.5.19.1 Device and Topology Information

First Byte (At offset 40 into the structure):

Bits 0:3:

- Value 0x0 -> No Additional Information about device topology.
- Value 0x1 -> More Information about device topology valid in this byte.
- Value 0x2 -> More Information about device topology valid in this and next 1 byte.
- Values 0x3 thru 0xF -> Reserved.

Bits 4:5: Device Type (Valid only if the More Information field above is non-zero)

- Value 0x0 -> SAS Internal Device
- Value 0x1 -> SATA Internal Device
- Value 0x2 -> SAS External Device
- Value 0x3 -> SATA External Device

Bits 6:7: Topology / Interconnect (Valid only if the More Information field above is non-zero)

- Value 0x0 -> Direct Connect (Connected directly with the HBA Port/Phy)
- Value 0x1 -> Expander Connect (Connected thru/via one or more Expanders)
- Value 0x2 and 0x3 > Reserved

9.3.5.19.2 Device and Topology Information

Second Byte (At offset 41 into the structure). Valid only if bits 0-3 of More Information in Byte 40 have a value of 2:

Bits 0-7: Internal Drive/Bay Id (Only applicable if Internal Drive is indicated in Device Type)

Value 0x0 thru 0xFF -> Drive 1 thru Drive 256

9.3.5.19.3 Relative Target Port

At offset 42 into the structure:

This two-byte field shall contain the “Relative Target Port” of the target SAS port. Relative Target Port can be obtained by performing an INQUIRY command to VPD page 0x83 in the target.

Implementation of RTP is mandatory for SAS targets as defined in Section 10.2.10 of sas1r07 specification (or later).

Note: *If a LUN is seen thru multiple RTPs in a given target, then the UEFI driver shall create separate device path instances for both paths. RTP in the device path shall distinguish these two device path instantiations.*

Note: *Changing the values of the SAS/SATA device topology information or the RTP fields of the device path will make UEFI think this is a different device.*

9.3.5.19.4 Examples Of Correct Device Path Display Format

Case 1: When Additional Information is not Valid or Not Present (Bits 0:3 of Byte 40 have a value of 0)

PciRoot(0) / PCI(1,0) / SAS(0x31000004CF13F6BD, 0)

Case 2: When Additional Information is Valid and present (Bits 0:3 of Byte 40 have a value of 1 or 2)

- If Bits 4-5 of Byte 40 (Device and Topology information) indicate an SAS device (Internal or External) i.e., has values 0x0 or 0x2, then the following format shall be used.

PciRoot(0) / PCI(1,0) / SAS(0x31000004CF13F6BD, 0, SAS)

- If Bits 4-5 of Byte 40 (Device and Topology information) indicate a SATA device (Internal or External) i.e., has a value of 0x1 or 0x3, then the following format shall be used.

ACPI(PnP) / PCI(1,0) / SAS(0x31000004CF13F6BD, SATA)

9.3.5.20 Serial Attached SCSI (SAS) Ex Device Path

This section defines the extended device node for Serial Attached SCSI (SAS) devices. In this device path the SAS Address and LUN are now defined as arrays to remove the need to endian swap the values.

Table 74. Messaging Device Path Structure

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type -3 Messaging
Sub Type	1	1	Sub-type 22 SAS Ex

Length	2	2	Length of this Structure. 32 bytes
SAS Address	4	8	8-byte array of the SAS Address for Serial Attached SCSI Target Port.
Logical Unit Number	20	8	8-byte array of the SAS Logical Unit Number.
SAS/SATA device and Topology Info	28	2	More Information about the device and its interconnect
Relative Target Port	30	2	Relative Target Port (RTP)

The SAS Ex device path clarifies the definition of the Logical Unit Number field to conform with the T-10 SCSI Architecture Model 4 specification. The 8 byte Logical Unit Number field in the device path must conform with a logical unit number returned by a SCSI REPORT LUNS command.

When the SAS Device Path Ex is used with the Extended SCSI Pass Thru Protocol, the UIN64 LUN must be converted to the eight byte array Logical Unit Number field in the device path by treating the eight byte array as an EFI UIN64. For example, a Logical Unit Number array of { 0,1,2,3,4,5,6,7 } becomes a UIN64 of 0x0706050403020100.

When an application client displays or otherwise makes a 64-bit LUN (8 byte array) visible to a user, it should be done in conformance with SAM-4. SAM-4 requires a LUN to be displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e., on the right) regardless of the internal representation of the LUN. UEFI defines all data structures a “little endian” and SCSI defines all data structures as “big endian”.

9.3.5.21 iSCSI Device Path

Table 75. iSCSI Device Path Node (Base Information)

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 19 – (iSCSI)
Length	2	2	Length of this structure in bytes. Length is (18 + n) bytes
Protocol	4	2	Network Protocol (0 = TCP, 1+ = reserved)
Options	6	2	iSCSI Login Options
Logical Unit Number	8	8	8 byte array containing the iSCSI Logical Unit Number
Target Portal group tag	16	2	iSCSI Target Portal group tag the initiator intends to establish a session with.
iSCSI Target Name	18	n	iSCSI NodeTarget Name. The length of the name is determined by subtracting the offset of this field from <i>Length</i> .

9.3.5.21.1 iSCSI Login Options

The iSCSI Device Node Options describe the iSCSI login options for the key values:

Bits 0:1:

- 0 = No Header Digest
- 2 = Header Digest Using CRC32C

Bits 2-3:

- 0 = No Data Digest
- 2 = Data Digest Using CRC32C

Bits 4:9:

Reserved for future use

Bits 10-11:

- 0 = AuthMethod_CHAP
- 2 = AuthMethod_None

Bit 12:

- 0 = CHAP_BI
- 1 = CHAP_UNI

For each specific login key, none, some or all of the defined values may be configured. If none of the options are defined for a specific key, the iSCSI driver shall propose “None” as the value. If more than one option is configured for a specific key, all the configured values will be proposed (ordering of the values is implementation dependent).

- Portal Group Tag: defines the iSCSI portal group the initiator intends to establish Session with.
- Logical Unit Number: defines the 8 byte SCSI LUN. The Logical Unit Number field must conform to the T-10 SCSI Architecture Model 4 specification. The 8 byte Logical Unit Number field in the device path must conform with a logical unit number returned by a SCSI REPORT LUNS command.
- iSCSI Target Name: defines the iSCSI Target Name for the iSCSI Node. The size of the iSCSI Target Name can be up to a maximum of 223 bytes.

9.3.5.21.2 Device Path Examples

Some examples for the Device Path for the case the boot device connected to iSCSI bootable controller:

- With IPv4 configuration:

```
PciRoot(0)/Pci(19|0)/Mac(001320F5FA77,0x01)/
IPv4(192.168.0.100,TCP,Static,192.168.0.1)/iSCSI(iqn.1991-
05.com.microsoft:iscsitarget-iscsidisk-
target,0x1,0x0,None,None,None,TCP)/HD(1,GPT,15E39A00-1DD2-1000-
8D7F-00A0C92408FC,0x22,0x2710000)
```

Table 76. IPv4 configuration

Byte Offset	Byte Length	Data	Description
0x00	1	0x02	Generic Device Path Header – Type ACPI Device Path

0xF2	1	0xFF	Sub type – End of Entire Device Path
0xF3	2	0x04	Length – 0x04 bytes

9.3.5.22 NVM Express namespace messaging device path node

Table 78. NVM Express Namespace Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub Type 23 – NVM Express Namespace
Length	2	2	Length of this structure in bytes. Length is 16 bytes.
Namespace Identifier	4	4	Namespace identifier (NSID). The values of 0 and 0xFFFFFFFF are invalid.
IEEE Extended Unique Identifier	8	8	This field contains the IEEE Extended Unique Identifier (EUI-64). Devices without an EUI-64 value must initialize this field with a value of 0.

Refer to the latest NVM Express specification for descriptions of Namespace Identifier (NSID) and IEEE Extended Unique Identifier (EUI-64): See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the headings “NVM Express Specification”.

9.3.5.23 Uniform Resource Identifiers (URI) Device Path

Refer to RFC 3986 for details on the URI contents.

Table 79. URI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub Type 24 – Universal Resource Identifier (URI) Device Path
Length	2	2	Length of this structure in bytes. Length is 4 + <i>n</i> bytes.
...	4	<i>n</i>	Instance of the URI pursuant to RFC 3986. For an empty URI, Length is 4 bytes.

9.3.5.24 UFS (Universal Flash Storage) device messaging device path node

Table 80. UFS Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 25 – UFS
Length	2	2	Length of this structure in bytes. Length is 6 bytes.
Target ID	4	1	Target ID on the UFS interface (PUN).
LUN	5	1	Logical Unit Number (LUN).

Refer to the UFS 2.0 specification for additional LUN descriptions: See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “UFS 2.0 Specification”.

- *PUN field*: According to current available UFS 2.0 spec, the topology is one device per UFS port. A topology to support multiple devices on a single interface is planned for future revision. So suggest to reserve/introduce this field to support multiple devices per UFS port. This value should be 0 for current UFS2.0 spec compliance.
- *LUN field*: This field is used to specify up to 8 normal LUNs(0-7) and 4 well-known LUNs(81h, D0h, B0h and C4h). For those well-known LUNs, the BIT7 is set. See Figure 10.2 of UFS 2.0 spec for details.

9.3.5.25 SD (Secure Digital) Device Path

Table 81. SD Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 26 – SD
Length	2	2	Length of this structure in bytes. Length is 5 bytes.
Slot Number	4	1	Slot Number

9.3.5.26 EFI Bluetooth Device Path

Table 82. Bluetooth Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 27 – Bluetooth
Length	2	2	Length of this structure in bytes. Length is 10 bytes.
Bluetooth Device Address	4	6	48-bit Bluetooth device address.

9.3.5.27 Wireless Device Path

Table 83. Wi-Fi Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub Type 28 – Wi-Fi Device Path
Length	2	2	Length of this structure in bytes. Length is 36 bytes.
SSID	4	32	SSID in octet string

9.3.5.28 eMMC (Embedded Multi-Media Card) Device Path

Table 84. eMMC Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 29 – eMMC
Length	2	2	Length of this structure in bytes. Length is 5 bytes.
Slot Number	4	1	Slot Number

9.3.6 Media Device Path

This Device Path is used to describe the portion of the medium that is being abstracted by a boot service. An example of Media Device Path would be defining which partition on a hard drive was being used.

9.3.6.1 Hard Drive

The Hard Drive Media Device Path is used to represent a partition on a hard drive. Each partition has at least Hard Drive Device Path node, each describing an entry in a partition table. EFI supports MBR and GPT partitioning formats. Partitions are numbered according to their entry in their respective partition table, starting with 1. Partitions are addressed in EFI starting at LBA zero. A partition number of zero can be used to represent the raw hard drive or a raw extended partition.

The partition format is stored in the Device Path to allow new partition formats to be supported in the future. The Hard Drive Device Path also contains a Disk Signature and a Disk Signature Type. The disk signature is maintained by the OS and only used by EFI to partition Device Path nodes. The disk signature enables the OS to find disks even after they have been physically moved in a system.

[Section 3.1.2](#) defines special rules for processing the Hard Drive Media Device Path. These special rules enable a disk's location to change and still have the system boot from the disk.

Table 85. Hard Drive Media Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 – Media Device Path
Sub-Type	1	1	Sub-Type 1 – Hard Drive
Length	2	2	Length of this structure in bytes. Length is 42 bytes.
Partition Number	4	4	Describes the entry in a partition table, starting with entry 1. Partition number zero represents the entire device. Valid partition numbers for a MBR partition are [1, 4]. Valid partition numbers for a GPT partition are [1, NumberOfPartitionEntries].
Partition Start	8	8	Starting LBA of the partition on the hard drive
Partition Size	16	8	Size of the partition in units of Logical Blocks

Mnemonic	Byte Offset	Byte Length	Description
Partition Signature	24	16	Signature unique to this partition: <ul style="list-style-type: none"> If SignatureType is 0, this field has to be initialized with 16 zeroes. If SignatureType is 1, the MBR signature is stored in the first 4 bytes of this field. The other 12 bytes are initialized with zeroes. If SignatureType is 2, this field contains a 16 byte signature.
Partition Format	40	1	Partition Format: (Unused values reserved) 0x01 – PC-AT compatible legacy MBR (see Section 5.2.1). Partition Start and Partition Size come from <code>PartitionStartingLBA</code> and <code>PartitionSizeInLBA</code> for the partition. 0x02 – GUID Partition Table (see Section 5.3.2).
Signature Type	41	1	Type of Disk Signature: (Unused values reserved) 0x00 – No Disk Signature. 0x01 – 32-bit signature from address 0x1b8 of the type 0x01 MBR. 0x02 – GUID signature.

9.3.6.2 CD-ROM Media Device Path

The CD-ROM Media Device Path is used to define a system partition that exists on a CD-ROM. The CD-ROM is assumed to contain an ISO-9660 file system and follow the CD-ROM “El Torito” format. The Boot Entry number from the Boot Catalog is how the “El Torito” specification defines the existence of bootable entities on a CD-ROM. In EFI the bootable entity is an EFI System Partition that is pointed to by the Boot Entry.

Table 86. CD-ROM Media Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 – Media Device Path.
Sub-Type	1	1	Sub-Type 2 – CD-ROM “El Torito” Format.
Length	2	2	Length of this structure in bytes. Length is 24 bytes.
Boot Entry	4	4	Boot Entry number from the Boot Catalog. The Initial/Default entry is defined as zero.
Partition Start	8	8	Starting RBA of the partition on the medium. CD-ROMs use Relative logical Block Addressing.
Partition Size	16	8	Size of the partition in units of Blocks, also called Sectors.

9.3.6.3 Vendor-Defined Media Device Path

Table 87. Vendor-Defined Media Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 – Media Device Path.
Sub-Type	1	1	Sub-Type 3 – Vendor.
Length	2	2	Length of this structure in bytes. Length is 20 + n bytes.
Vendor GUID	4	16	Vendor-assigned GUID that defines the data that follows.
Vendor Defined Data	20	n	Vendor-defined variable size data.

9.3.6.4 File Path Media Device Path

Table 88. File Path Media Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 – Media Device Path.
Sub-Type	1	1	Sub-Type 4 – File Path.
Length	2	2	Length of this structure in bytes. Length is 4 + n bytes.
Path Name	4	N	A NULL-terminated Path string including directory and file names. The length of this string n can be determined by subtracting 4 from the Length entry. A device path may contain one or more of these nodes. Each node can optionally add a "\" separator to the beginning and/or the end of the Path Name string. The complete path to a file can be found by logically concatenating all the Path Name strings in the File Path Media Device Path nodes. This is typically used to describe the directory path in one node, and the filename in another node.

Rules for Path Name conversion:

- When concatenating two Path Names, ensure that the resulting string does not contain a double-separator "\". If it does, convert that double-separator to a single-separator.
- In the case where a Path Name which has no end separator is being concatenated to a Path Name with no beginning separator, a separator will need to be inserted between the Path Names.
- Single file path nodes with no directory path data are presumed to have their files located in the root directory of the device.

9.3.6.5 Media Protocol Device Path

The Media Protocol Device Path is used to denote the protocol that is being used in a device path at the location of the path specified. Many protocols are inherent to the style of device path.

Table 89. Media Protocol Media Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 – Media Device Path.
Sub-Type	1	1	Sub-Type 5 – Media Protocol.
Length	2	2	Length of this structure in bytes. Length is 20 bytes.
Protocol GUID	4	16	The ID of the protocol.

9.3.6.6 PIWG Firmware File

This type is used by systems implementing the UEFI PI Specification to describe a firmware file. The exact format and usage are defined in that specification.

Table 90. PIWG Firmware Volume Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 – Media Device Path.
Sub-Type	1	1	Sub-Type 6 – PIWG Firmware File.
Length	2	2	Length of this structure in bytes. Length is 4 + <i>n</i> bytes.
...	4	<i>n</i>	Contents are defined in the UEFI PI Specification.

9.3.6.7 PIWG Firmware Volume

This type is used by systems implementing the UEFI PI Specification to describe a firmware volume. The exact format and usage are defined in that specification.

Table 91. PIWG Firmware Volume Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 – Media Device Path.
Sub-Type	1	1	Sub-Type 7 – PIWG Firmware Volume.
Length	2	2	Length of this structure in bytes. Length is 4 + <i>n</i> bytes.
...	4	<i>n</i>	Contents are defined in the UEFI PI Specification.

9.3.6.8 Relative Offset Range

This device path node specifies a range of offsets relative to the first byte available on the device. The starting offset is the first byte of the range and the ending offset is the last byte of the range (not the last byte + 1).

Table 92. Relative Offset Range

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 – Media Device Path

Sub-Type	1	1	Sub-Type 8 – Relative Offset Range
Length	2	2	Length of this structure in bytes.
Reserved	4	4	Reserved for future use.
Starting Offset	8	8	Offset of the first byte, relative to the parent device node.
Ending Offset	16	8	Offset of the last byte, relative to the parent device node.

9.3.6.9 RAM Disk

Table 93. RAM Disk Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 – Media Device Path
Sub-Type	1	1	Sub Type 9 – RAM Disk Device Path
Length	2	2	Length of this structure in bytes. Length is 38 bytes.
Starting Address	4	8	Starting Memory Address.
Ending Address	12	8	Ending Memory Address.
Disk Type GUID	20	16	GUID that defines the type of the RAM Disk. The GUID can be any of the values defined below, or a vendor defined GUID.
Disk Instance	36	2	RAM Disk instance number, if supported. The default value is zero.

The following GUIDs are used with a RAM Disk Device Path to describe the RAM Disk Type. Additional GUIDs can be generated to describe additional RAM Disk Types. The Disk Type GUID values used in the RAM Disk device path must match the corresponding values in the Address Range Type GUID of the ACPI NFIT table. Refer to the ACPI specification for details.

This GUID defines a RAM Disk supporting a raw disk format in volatile memory:

```
#define EFI_VIRTUAL_DISK_GUID \
{ 0x77AB535A, 0x45FC, 0x624B, \
  {0x55, 0x60, 0xF7, 0xB2, 0x81, 0xD1, 0xF9, 0x6E } }
```

This GUID defines a RAM Disk supporting an ISO image in volatile memory:

```
#define EFI_VIRTUAL_CD_GUID \
{ 0x3D5ABD30, 0x4175, 0x87CE, \
  {0x6D, 0x64, 0xD2, 0xAD, 0xE5, 0x23, 0xC4, 0xBB } }
```

This GUID defines a RAM Disk supporting a raw disk format in persistent memory:

```
#define EFI_PERSISTENT_VIRTUAL_DISK_GUID \
{ 0x5CEA02C9, 0x4D07, 0x69D3, \
  {0x26, 0x9F, 0x44, 0x96, 0xFB, 0xE0, 0x96, 0xF9 } }
```

This GUID defines a RAM Disk supporting an ISO image in persistent memory:

```
#define EFI_PERSISTENT_VIRTUAL_CD_GUID \
{ 0x08018188, 0x42CD, 0xBB48, \
{ 0x10, 0x0F, 0x53, 0x87, 0xD5, 0x3D, 0xED, 0x3D } }
```

9.3.7 BIOS Boot Specification Device Path

This Device Path is used to describe the booting of non-EFI-aware operating systems. This Device Path is based on the IPL and BCV table entry data structures defined in Appendix A of the *BIOS Boot Specification*. The BIOS Boot Specification Device Path defines a complete Device Path and is not used with other Device Path entries. This Device Path is only needed to enable platform firmware to select a legacy non-EFI OS as a boot option.

Table 94. BIOS Boot Specification Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 5 – BIOS Boot Specification Device Path.
Sub-Type	1	1	Sub-Type 1 – BIOS Boot Specification Version 1.01.
Length	2	2	Length of this structure in bytes. Length is 8 + <i>n</i> bytes.
Device Type	4	2	Device Type as defined by the BIOS Boot Specification.
Status Flag	6	2	Status Flags as defined by the BIOS Boot Specification
Description String	8	<i>n</i>	A null-terminated ASCII string that describes the boot device to a user. The size of this string <i>n</i> can be determined by subtracting 8 from the Length entry.

Example BIOS Boot Specification Device Types include:

- 00h = Reserved
- 01h = Floppy
- 02h = Hard Disk
- 03h = CD-ROM
- 04h = PCMCIA
- 05h = USB
- 06h = Embedded network
- 07h..7Fh = Reserved
- 80h = BEV device
- 81h..FEh = Reserved
- FFh = Unknown

Note: When UEFI Secure Boot is enabled, attempts to boot non-UEFI OS shall fail; see [Section 30.4](#).

9.4 Device Path Generation Rules

9.4.1 Housekeeping Rules

The Device Path is a set of Device Path nodes. The Device Path must be terminated by an End of Device Path node with a sub-type of End the Entire Device Path. A NULL Device Path consists of a single End Device Path Node. A Device Path that contains a NULL pointer and no Device Path structures is illegal.

All Device Path nodes start with the generic Device Path structure. Unknown Device Path types can be skipped when parsing the Device Path since the length field can be used to find the next Device Path structure in the stream. Any future additions to the Device Path structure types will always start with the current standard header. The size of a Device Path can be determined by traversing the generic Device Path structures in each header and adding up the total size of the Device Path. This size will include the four bytes of the End of Device Path structure.

Multiple hardware devices may be pointed to by a single Device Path. Each hardware device will contain a complete Device Path that is terminated by the Device Path End Structure. The Device Path End Structures that do not end the Device Path contain a sub-type of End This Instance of the Device Path. The last Device Path End Structure contains a sub-type of End Entire Device Path.

9.4.2 Rules with ACPI _HID and _UID

As described in the ACPI specification, ACPI supports several different kinds of device identification objects, including _HID, _CID and _UID. The _UID device identification objects are optional in ACPI and only required if more than one _HID exists with the same ID. The ACPI Device Path structure must contain a zero in the _UID field if the ACPI name space does not implement _UID. The _UID field is a unique serial number that persists across reboots.

If a device in the ACPI name space has a _HID and is described by a _CRS (Current Resource Setting) then it should be described by an ACPI Device Path structure. A _CRS implies that a device is not mapped by any other standard. A _CRS is used by ACPI to make a nonstandard device into a Plug and Play device. The configuration methods in the ACPI name space allow the ACPI driver to configure the device in a standard fashion. The presence of a _CID determines whether the ACPI Device Path node or the Expanded ACPI Device Path node should be used.

[Table 95](#) maps ACPI _CRS devices to EFI Device Path.

Table 95. ACPI _CRS to EFI Device Path Mapping

ACPI _CRS Item	EFI Device Path
PCI Root Bus	ACPI Device Path: _HID PNP0A03, _UID
Floppy	ACPI Device Path: _HID PNP0604, _UID drive select encoding 0-3
Keyboard	ACPI Device Path: _HID PNP0301, _UID 0
Serial Port	ACPI Device Path: _HID PNP0501, _UID Serial Port COM number 0-3
Parallel Port	ACPI Device Path: _HID PNP0401, _UID LPT number 0-3

Support of root PCI bridges requires special rules in the EFI Device Path. A root PCI bridge is a PCI device usually contained in a chipset that consumes a proprietary bus and produces a PCI bus. In typical desktop and mobile systems there is only one root PCI bridge. On larger server systems there are typically multiple root PCI bridges. The operation of root PCI bridges is not defined in any current PCI specification. A root PCI bridge should not be confused with a PCI to PCI bridge that both consumes and produces a PCI bus. The operation and configuration of PCI to PCI bridges is fully specified in current PCI specifications.

Root PCI bridges will use the plug and play ID of PNP0A03, This will be stored in the ACPI Device Path `_HID` field, or in the Expanded ACPI Device Path `_CID` field to match the ACPI name space. The `_UID` in the ACPI Device Path structure must match the `_UID` in the ACPI name space.

9.4.3 Rules with ACPI `_ADR`

If a device in the ACPI name space can be completely described by a `_ADR` object then it will map to an EFI ACPI, Hardware, or Message Device Path structure. A `_ADR` method implies a bus with a standard enumeration algorithm. If the ACPI device has a `_ADR` and a `_CRS` method, then it should also have a `_HID` method and follow the rules for using `_HID`.

[Table 96](#) relates the ACPI `_ADR` bus definition to the EFI Device Path:

Table 96. ACPI `_ADR` to EFI Device Path Mapping

ACPI <code>_ADR</code> Bus	EFI Device Path
EISA	Not supported
Floppy Bus	ACPI Device Path: <code>_HID</code> PNP0604, <code>_UID</code> drive select encoding 0-3
IDE Controller	ATAPI Message Device Path: Maser/Slave : LUN
IDE Channel	ATAPI Message Device Path: Maser/Slave : LUN
PCI	PCI Hardware Device Path
PCMCIA	Not Supported
PC CARD	PC CARD Hardware Device Path
SMBus	Not Supported
SATA bus	SATA Messaging Device Path

9.4.4 Hardware vs. Messaging Device Path Rules

Hardware Device Paths are used to define paths on buses that have a standard enumeration algorithm and that relate directly to the coherency domain of the system. The coherency domain is defined as a global set of resources that is visible to at least one processor in the system. In a typical system this would include the processor memory space, IO space, and PCI configuration space.

Messaging Device Paths are used to define paths on buses that have a standard enumeration algorithm, but are not part of the global coherency domain of the system. SCSI and Fibre Channel are examples of this kind of bus. The Messaging Device Path can also be used to describe virtual connections over network-style devices. An example would be the TCP/IP address of an internet connection.

Thus Hardware Device Path is used if the bus produces resources that show up in the coherency resource domain of the system. A Message Device Path is used if the bus consumes resources from the coherency domain and produces resources out side the coherency domain of the system.

9.4.5 Media Device Path Rules

The Media Device Path is used to define the location of information on a medium. Hard Drives are subdivided into partitions by the MBR and a Media Device Path is used to define which partition is being used. A CD-ROM has boot partitions that are defined by the “El Torito” specification, and the Media Device Path is used to point to these partitions.

An [EFI_BLOCK_IO_PROTOCOL](#) is produced for both raw devices and partitions on devices. This allows the [EFI_SIMPLE_FILE_SYSTEM_PROTOCOL](#) protocol to not have to understand media formats. The [EFI_BLOCK_IO_PROTOCOL](#) for a partition contains the same Device Path as the parent [EFI_BLOCK_IO_PROTOCOL](#) for the raw device with the addition of a Media Device Path that defines which partition is being abstracted.

The Media Device Path is also used to define the location of a file in a file system. This Device Path is used to load files and to represent what file an image was loaded from.

9.4.6 Other Rules

The BIOS Boot Specification Device Path is not a typical Device Path. A Device Path containing the BIOS Boot Specification Device Path should only contain the required End Device Path structure and no other Device Path structures. The BIOS Boot Specification Device Path is only used to allow the EFI boot menus to boot a legacy operating system from legacy media.

The EFI Device Path can be extended in a compatible fashion by assigning your own vendor GUID to a Hardware, Messaging, or Media Device Path. This extension is guaranteed to never conflict with future extensions of this specification.

The EFI specification reserves all undefined Device Path types and subtypes. Extension is only permitted using a Vendor GUID Device Path entry.

9.5 Device Path Utilities Protocol

This section describes the [EFI_DEVICE_PATH_UTILITIES_PROTOCOL](#), which aids in creating and manipulating device paths.

EFI_DEVICE_PATH_UTILITIES_PROTOCOL

Summary

Creates and manipulates device paths and device nodes.

GUID

```
// {0379BE4E-D706-437d-B037-EDB82FB772A4}
#define EFI_DEVICE_PATH_UTILITIES_PROTOCOL_GUID \
    {0x379be4e, 0xd706, 0x437d, \
     0xb0, 0x37, 0xed, 0xb8, 0x2f, 0xb7, 0x72, 0xa4 }
```

Protocol Interface Structure

```
typedef struct _EFI_DEVICE_PATH_UTILITIES_PROTOCOL {
    EFI_DEVICE_PATH_UTILS_GET_DEVICE_PATH_SIZE  GetDevicePathSize;
    EFI_DEVICE_PATH_UTILS_DUP_DEVICE_PATH      DuplicateDevicePath;
    EFI_DEVICE_PATH_UTILS_APPEND_PATH          AppendDevicePath;
    EFI_DEVICE_PATH_UTILS_APPEND_NODE         AppendDeviceNode;
    EFI_DEVICE_PATH_UTILS_APPEND_INSTANCE
                                                AppendDevicePathInstance;
    EFI_DEVICE_PATH_UTILS_GET_NEXT_INSTANCE
                                                GetNextDevicePathInstance;
    EFI_DEVICE_PATH_UTILS_IS_MULTI_INSTANCE
                                                IsDevicePathMultiInstance;
    EFI_DEVICE_PATH_UTILS_CREATE_NODE          CreateDeviceNode;
} EFI_DEVICE_PATH_UTILITIES_PROTOCOL;
```

Parameters

GetDevicePathSize Returns the size of the specified device path, in bytes.

DuplicateDevicePath Duplicates a device path structure.

AppendDeviceNode Appends the device node to the specified device path.

AppendDevicePath Appends the device path to the specified device path.

AppendDevicePathInstance
Appends a device path instance to another device path.

GetNextDevicePathInstance
Retrieves the next device path instance from a device path data structure.

IsDevicePathMultiInstance
Returns TRUE if this is a multi-instance device path.

CreateDeviceNode Allocates memory for a device node with the specified type and sub-type.

Description

The **EFI_DEVICE_PATH_UTILITIES_PROTOCOL** provides common utilities for creating a manipulating device paths and device nodes.

EFI_DEVICE_PATH_UTILITIES_PROTOCOL.GetDevicePathSize()

Summary

Returns the size of the device path, in bytes.

Prototype

```
typedef
UINTN
(EFIAPI *EFI_DEVICE_PATH_UTILS_GET_DEVICE_PATH_SIZE) (
    IN CONST EFI_DEVICE_PATH_PROTOCOL *DevicePath
);
```

Parameters

DevicePath Points to the start of the EFI device path.

Description

This function returns the size of the specified device path, in bytes, including the end-of-path tag. If *DevicePath* is **NULL** then zero is returned.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

EFI_DEVICE_PATH_UTILITIES_PROTOCOL.DuplicateDevicePath()

Summary

Create a duplicate of the specified path.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_UTILS_DUP_DEVICE_PATH) (
    IN CONST EFI_DEVICE_PATH_PROTOCOL  *DevicePath
);
```

Parameters

DevicePath Points to the source device path.

Description

This function creates a duplicate of the specified device path. The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated. If *DevicePath* is **NULL** then **NULL** will be returned and no memory will be allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns a pointer to the duplicate device path or NULL if there was insufficient memory.

EFI_DEVICE_PATH_UTILITIES_PROTOCOL.AppendDevicePath()

Summary

Create a new path by appending the second device path to the first.

Prototype

```

typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_UTILS_APPEND_PATH) (
    IN CONST EFI_DEVICE_PATH_PROTOCOL *Src1,
    IN CONST EFI_DEVICE_PATH_PROTOCOL *Src2
);

```

Parameters

<i>Src1</i>	Points to the first device path.
<i>Src2</i>	Points to the second device path.

Description

This function creates a new device path by appending a copy of the second device path to a copy of the first device path in a newly allocated buffer. Only the end-of-device-path device node from the second device path is retained. If *Src1* is **NULL** and *Src2* is non-**NULL**, then a duplicate of *Src2* is returned. If *Src1* is non-**NULL** and *Src2* is **NULL**, then a duplicate of *Src1* is returned. If *Src1* and *Src2* are both **NULL**, then a copy of an end-of-device-path is returned.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns a pointer to the newly created device path or **NULL** if memory could not be allocated.

EFI_DEVICE_PATH_UTILITIES_PROTOCOL.AppendDeviceNode()

Summary

Creates a new path by appending the device node to the device path.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFI_API *EFI_DEVICE_PATH_UTILS_APPEND_NODE) (
    IN CONST EFI_DEVICE_PATH_PROTOCOL *DevicePath,
    IN CONST EFI_DEVICE_PATH_PROTOCOL *DeviceNode
);
```

Parameters

<i>DevicePath</i>	Points to the device path.
<i>DeviceNode</i>	Points to the device node.

Description

This function creates a new device path by appending a copy of the specified device node to a copy of the specified device path in an allocated buffer. The end-of-device-path device node is moved after the end of the appended device node. If *DeviceNode* is **NULL** then a copy of *DevicePath* is returned. If *DevicePath* is **NULL** then a copy of *DeviceNode*, followed by an end-of-device path device node is returned. If both *DeviceNode* and *DevicePath* are **NULL** then a copy of an end-of-device-path device node is returned.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns a pointer to the allocated device path, or **NULL** if there was insufficient memory.

EFI_DEVICE_PATH_UTILITIES_PROTOCOL.AppendDevicePathInstance()

Summary

Creates a new path by appending the specified device path instance to the specified device path.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFI_API *EFI_DEVICE_PATH_UTILS_APPEND_INSTANCE) (
    IN CONST EFI_DEVICE_PATH_PROTOCOL *DevicePath,
    IN CONST EFI_DEVICE_PATH_PROTOCOL *DevicePathInstance
);
```

Parameters

DevicePath Points to the device path. If NULL, then ignored.
DevicePathInstance Points to the device path instance

Description

This function creates a new device path by appending a copy of the specified device path instance to a copy of the specified device path in an allocated buffer. The end-of-device-path device node is moved after the end of the appended device node and a new end-of-device-path-instance node is inserted between. If *DevicePath* is NULL, then a copy of *DevicePathInstance* is returned instead.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns a pointer to the newly created device path or NULL if *DevicePathInstance* is NULL or there was insufficient memory.

EFI_DEVICE_PATH_UTILITIES_PROTOCOL.GetNextDevicePathInstance()

Summary

Creates a copy of the current device path instance and returns a pointer to the next device path instance.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFI_API *EFI_DEVICE_PATH_UTILS_GET_NEXT_INSTANCE) (
    IN OUT EFI_DEVICE_PATH_PROTOCOL **DevicePathInstance,
    OUT UINTN                               *DevicePathInstanceSize OPTIONAL
);
```

Parameters

DevicePathInstance On input, this holds the pointer to the current device path instance. On output, this holds the pointer to the next device path instance or NULL if there are no more device path instances in the device path.

DevicePathInstanceSize On output, this holds the size of the device path instance, in bytes or zero, if *DevicePathInstance* is **NULL**. If **NULL**, then the instance size is not output.

Description

This function creates a copy of the current device path instance. It also updates *DevicePathInstance* to point to the next device path instance in the device path (or NULL if no more) and updates *DevicePathInstanceSize* to hold the size of the device path instance copy.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns a pointer to the copy of the current device path instance or NULL if *DevicePathInstance* was NULL on entry or there was insufficient memory.

EFI_DEVICE_PATH_UTILITIES_PROTOCOL.CreateDeviceNode()**Summary**

Creates a device node

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFI_API *EFI_DEVICE_PATH_UTILS_CREATE_NODE) (
    IN UINT8  NodeType,
    IN UINT8  NodeSubType,
    IN UINT16 NodeLength
);
```

Parameters

<i>NodeType</i>	NodeType is the device node type (EFI_DEVICE_PATH_PROTOCOL.Type) for the new device node.
<i>NodeSubType</i>	NodeSubType is the device node sub-type (EFI_DEVICE_PATH_PROTOCOL.SubType) for the new device node.
<i>NodeLength</i>	NodeLength is the length of the device node (EFI_DEVICE_PATH_PROTOCOL.Length) for the new device node.

Description

This function creates a new device node in a newly allocated buffer.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns a pointer to the created device node or NULL if *NodeLength* is less than the size of the header or there was insufficient memory.

EFI_DEVICE_PATH_UTILITIES_PROTOCOL.IsDevicePathMultiInstance()

Summary

Returns whether a device path is multi-instance.

Prototype

```
typedef
BOOLEAN
(EFI_API *EFI_DEVICE_PATH_UTILS_IS_MULTI_INSTANCE) (
    IN CONST EFI_DEVICE_PATH_PROTOCOL    *DevicePath
);
```

Parameters

DevicePath Points to the device path. If **NULL**, then ignored.

Description

This function returns whether the specified device path has multiple path instances.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns TRUE if the device path has more than one instance or FALSE if it is empty or contains only a single instance.

9.6 EFI Device Path Display Format Overview

This section describes the recommended conversion between an EFI Device Path Protocol and text. It also describes standard protocols for implementing these. The goals are:

- Standardized display format. This allows documentation and test tools to understand output coming from drivers provided by multiple vendors.
- Increase Readability. Device paths need to be read by people, so the format should be in a form which can be deciphered, maintaining as much as possible the industry standard means of presenting data. In this case, there are two forms, a display-only form and a parse-able form.
- Round-trip conversion from text to binary form and back to text without loss, if desired.
- Ease of command-line parsing. Since device paths can appear on the command-lines of UEFI applications executed from a shell, the conversion format should not prohibit basic command-line processing, either by the application or by a shell.

9.6.1 Design Discussion

The following subsections describe the design considerations for conversion to and from the EFI Device Path Protocol binary format and its corresponding text form.

9.6.1.1 Standardized Display Format

Before the UEFI 2.0, there was no standardized format for the conversion from the EFI Device Path protocol and text. Some de-facto standards arose, either as part of the standard implementation or in descriptive text in the EFI Device Driver Writer's Guide, although they didn't agree. The standardized format attempts to maintain at least the spirit of these earlier ideas.

9.6.1.2 Readability

Since these are conversions to text and, in many cases, users have to read and understand the text form of the EFI Device Path, it makes sense to make them as readable as reasonably possible.

Several strategies are used to accomplish this:

- Creating simplified forms for well-known device paths. For example, a PCI root Bridge can be represented as Acpi(PNP0A03,0), but makes more sense as PciRoot(0). When converting from text to binary form, either form is accepted, but when converting from binary form to text, the latter is preferred.
- Omitting the conversion of fields which have empty or default values. By doing this, the average display length is greatly shortened, which improves readability.

9.6.1.3 Round-Trip Conversion

The conversions specified here guarantee at least that conversion to and from the binary representation of the EFI Device Path will be semantically identical.

$$\text{Text}_1 \Leftrightarrow \text{Binary}_1 \Leftrightarrow \text{Text}_2 \Leftrightarrow \text{Binary}_2$$

Figure 23. Text to Binary Conversion

In [Figure 23](#), the process described in this section is applied to Text1, converting it to Binary1. Subsequently, Binary1 is converted to Text2. Finally, the Text2 is converted to Binary2. In these cases, Binary1 and Binary2 will always be identical. Text1 and Text2 may or may not be identical. This is the result of the fact that the text representation has, in some cases, more than one way of representing the same EFI Device Path node.

$$\text{Binary}_1 \Leftrightarrow \text{Text}_1 \Leftrightarrow \text{Binary}_2 \Leftrightarrow \text{Text}_2$$

Figure 24. Binary to Text Conversion

In [Figure 24](#) the process described in this section is applied to Binary1, converting it to Text1. Subsequently, Text1 is converted to Binary2. Finally, Binary2 is converted to Text2. In these cases, Binary1 and Binary2 will always be identical and Text1 and Text2 will always be identical.

Another consideration in round-trip conversion is potential ambiguity in parsing. This happens when the text representation could be converted into more than type of device node, thus requiring information beyond that contained in the text representation in order to determine the correct conversion to apply. In the case of EFI Device Paths, this causes problems primarily with literal strings in the device path, such as those found in file names, volumes or directories.

For example, the file name Acpi(PNP0A03,0) might be a legal FAT32 file name. However, in parsing this, it is not clear whether it refers to an Acpi device node or a file name. Thus, it is ambiguous. In order to prevent ambiguity, certain characters may only be used for device node keywords and may not be used in file names or directories.

9.6.1.4 Command-Line Parsing

Applications written to this specification need to accept the text representation of EFI device paths as command-line parameters, possibly in the context of a command-prompt or shell. In order to do this, the text representation must follow simple guidelines concerning its format.

Command-line parsing generally involves three separate concepts: substitution, redirection and division.

In substitution, the invoker of the application modifies the actual contents of the command-line before it is passed to the application. For example:

```
copy *.xyz
```

In redirection, the invoker of the application gleans from the command line parameters which it uses to, for example, redirect or pipe input or output. For example:

```
echo This text is copied to a file >abc
dir | more
```

Finally, in division, the invoker or the application startup code divides the command-line up into individual arguments. The following line, for example, has (at least) three arguments, divided by whitespace.

```
copy /b file1.info file2.info
```

9.6.1.5 Text Representation Basics

This section describes the basic rules for the text representation of device nodes and device paths. The formal grammar describing appears later.

The text representation of a device path (or text device path) consists of one or more text device nodes, each preceded by a '/' or '\' character. The behavior of a device path where the first node is not preceded by one of these characters is undefined. Some implementations may treat it as a relative path from a current working directory.

Spaces are not allowed at any point within the device path except when quoted with double quotes (""). The '|' (bar), '<' (less than) and '>' (greater than) characters are likewise reserved for use by the shell.

```

device-path:=  \ device-node
                / device-node
                \ device-path device-node
                / device-path device-node

```

Figure 25. Device Path Text Representation

There are two types of text device nodes : file-name/directory or canonical. Canonical text device nodes are prefixed by an option name consisting of only alphanumerical characters, followed by a parenthesis, followed by option-specific parameters separated by a ‘,’ (comma). File names and directories have no prefixes.

```

device-node := standard-device-node | file-name/directory
standard-device-node := option-name(option-parameters)
file-name/directory := any character except ‘/’ ‘\’ ‘|’ ‘>’ ‘<’
    
```

Figure 26. Text Device Node Names

The canonical device node can have zero or more option parameters between the parentheses. Multiple option parameters are separated by a comma. The meaning of the option parameters depends primarily on the option name, then the parameter-identifier (if present) and then the order of appearance in the parameter list. The parameter identifier allows the text representation to only contain the non-default option parameter value, even if it would normally appear fourth in the list of option parameters. Missing parameters do not require the comma unless needed as a placeholder to correctly increment the parameter count for a subsequent parameter.

Consider

```
AcpiEx(HWP0002, PNP0A03,0)
```

Which could also be written:

```
AcpiEx(HWP0002,CID=PNP0A03) or
AcpiEx(HWP0002,PNP0A03)
```

Since CID and UID are optional parameters. Or consider:

```
Acpi(HWP0002,0)
```

Which could also be written:

```
Acpi(HWP0002)
```

Since UID is an optional parameter.

option-name := alphanumerical characters string
option-parameters :=*option-parameter*
option-parameters,option-parameter
option-parameter :=parameter-value
parameter-identifier=parameter-value

Figure 27. Device Node Option Names

9.6.1.6 Text Device Node Reference

In each of the following table rows, a specific device node type and sub-type are given, along with the most general form of the text representation. Any parameters for the device node are listed in italics. In each case, the type is listed and along with it what is required or optional, and any default value, if applicable.

On subsequent lines, alternate representations are listed. In general, these alternate representations are simplified by the assumption that one or more of the parameters is set to a specific value.

Parameter Types

This section describes the various types of option parameter values.

Table 97. EFI Device Path Option Parameter Values

GUID	An EFI GUID in standard format xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx. See “GUID and Time Formats” on page 2335.
Keyword	In some cases, one of a series of keywords must be listed.
Integer	Unless otherwise specified, this indicates an unsigned integer in the range of 0 to 2 ³² -1. The value is decimal, unless preceded by “0x” or “0X”, in which case it is hexadecimal.
EISAID	A seven character text identifier in the format used by the ACPI specification. The first three characters must be alphabetic, either upper or lower case. The second four characters are hexadecimal digits, either numeric, upper case or lower case. Optionally, it can be the number 0.
String	Series of alphabetic, numeric and punctuation characters not including a right parenthesis ‘)’, bar ‘ ’ less-than ‘<’ or greater than ‘>’ character.
HexDump	Series of bytes, represented by two hexadecimal characters per byte. Unless otherwise indicated, the size is only limited by the length of the device node.
IPv4 Address	Series of four integer values (each between 0-255), separated by a ‘.’ Optionally, followed by a ‘:’ and an integer value between 0-65555. If the ‘:’ is not present, then the port value is zero.

IPv6 Address	IPv6 Address is expressed in the format [address]:port. The 'address' is expressed in the way defined in RFC4291 Section 2.2. The ':port' after the [address] is optional. If present, the 'port' is an integer value between 0-65535 to represent the port number, or else, port number is zero..
--------------	--

Table 98. Device Node Table

Device Node Type/SubType/Other	Description
(when type is not recognized)	Path (<i>type, subtype, data</i>) The <i>type</i> is an integer from 0-255. The <i>sub-type</i> is an integer from 0-255. The <i>data</i> is a hex dump.
Type: 1 (Hardware Device Path) (when subtype is not recognized)	HardwarePath (<i>subtype, data</i>) The <i>subtype</i> is an integer from 0-255. The <i>data</i> is a hex dump.
Type: 1 (Hardware Device Path) SubType: 1 (PCI)	Pci (<i>Device, Function</i>) The <i>Device</i> is an integer from 0-31 and is required. The <i>Function</i> is an integer from 0-7 and is required.
Type: 1 (Hardware Device Path) SubType: 2 (PcPcard)	PcCard (<i>Function</i>) The <i>Function</i> is an integer from 0-255 and is required.
Type: 1 (Hardware Device Path) SubType: 3 (Memory Mapped)	MemoryMapped (<i>EfiMemoryType, StartingAddress, EndingAddress</i>) The <i>EfiMemoryType</i> is a 32-bit integer and is required. The <i>StartingAddress</i> and <i>EndingAddress</i> are both 64-bit integers and are both required.
Type: 1 (Hardware Device Path) SubType: 4 (Vendor)	VenHw (<i>Guid, Data</i>) The <i>Guid</i> is a GUID and is required. The <i>Data</i> is a Hex Dump and is optional. The default value is zero bytes.
Type: 1 (Hardware Device Path) SubType: 5 (Controller)	Ctrl (<i>Controller</i>) The <i>Controller</i> is an integer and is required.
Type: 1 (Hardware Device Path) SubType: 6 (BMC)	BMC (<i>Type,Address</i>) The <i>Type</i> is an integer from 0-255, and is required. The <i>Address</i> is an unsigned 64-bit integer, and is required.
Type: 2 (ACPI Device Path) (when subtype is not recognized)	AcpiPath (<i>subtype, data</i>) The <i>subtype</i> is an integer from 0-255. The <i>data</i> is a hex dump.

Device Node Type/SubType/Other	Description
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path)	Acpi(<i>HID,UID</i>) The <i>HID</i> parameter is an EISAID and is required. The <i>UID</i> parameter is an integer and is optional. The default value is zero.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0A03	PciRoot(<i>UID</i>) The <i>UID</i> parameter is an integer. It is optional but required for display. The default value is zero.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0A08	PcieRoot(<i>UID</i>) The <i>UID</i> parameter is an integer. It is optional but required for display. The default value is zero.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0604	Floppy(<i>UID</i>) The <i>UID</i> parameter is an integer. It is optional for input but required for display. The default value is zero.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0301	Keyboard(<i>UID</i>) The <i>UID</i> parameter is an integer. It is optional for input but required for display. The default value is 0.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0501	Serial(<i>UID</i>) The <i>UID</i> parameter is an integer. It is optional for input but required for display. The default value is 0.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0401	ParallelPort(<i>UID</i>) The <i>UID</i> parameter is an integer. It is optional for input but required for display. The default value is 0.
Type: 2 (ACPI Device Path) SubType: 2 (ACPI Expanded Device Path)	AcpiEx(<i>HID,CID,UID,HIDSTR,CIDSTR,UIDSTR</i>) AcpiEx(<i>HID HIDSTR,(CID CIDSTR,UID UIDSTR)</i>)(Display Only) The <i>HID</i> parameter is an EISAID. The default value is 0. Either <i>HID</i> or <i>HIDSTR</i> must be present. The <i>CID</i> parameter is an EISAID. The default value is 0. Either <i>CID</i> must be 0 or <i>CIDSTR</i> must be empty. The <i>UID</i> parameter is an integer. The default value is 0. Either <i>UID</i> must be 0 or <i>UIDSTR</i> must be empty. The <i>HIDSTR</i> is a string. The default value is the empty string. Either <i>HID</i> or <i>HIDSTR</i> must be present. The <i>CIDSTR</i> is a string. The default value is an empty string. Either <i>CID</i> must be 0 or <i>CIDSTR</i> must be empty. The <i>UIDSTR</i> is a string. The default value is an empty string. Either <i>UID</i> must be 0 or <i>UIDSTR</i> must be empty.

Unified Extensible Firmware Interface Specification

Device Node Type/SubType/ Other	Description
Type: 2 (ACPI Device Path) SubType: 2 (ACPI Expanded Device Path) HIDSTR=empty CIDSTR=empty UID STR!=empty	AcpiExp (<i>HID,CID,UIDSTR</i>) The <i>HID</i> parameter is an EISAID. It is required. The <i>CID</i> parameter is an EISAID. It is optional and has a default value of 0. The <i>UIDSTR</i> parameter is a string. If UID is 0 and UIDSTR is empty, then use AcpiEx format.
Type: 2 (ACPI Device Path) SubType: 2 (ACPI Expanded Device Path) HID=PNP0A03 or CID=PNP0A03 and HID != PNP0A08.	PciRoot (<i>UID UIDSTR</i>) (Display Only)
Type: 2 (ACPI Device Path) SubType: 2 (ACPI Expanded Device Path) HID=PNP0A08 or CID=PNP0A08.	PcieRoot (<i>UID UIDSTR</i>) (Display Only)
Type: 2 (ACPI Device Path) SubType: 3 (ACPI ADR Device Path)	AcpiAdr (<i>DisplayDevice[, DisplayDevice...]</i>) The <i>DisplayDevice</i> parameter is an Integer. There may be one or more, separated by a comma.
Type: 3 MessagingPath (when subtype is not recognized)	Msg (<i>subtype, data</i>) The <i>subtype</i> is an integer from 0-255. The <i>data</i> is a hex dump.
Type: 3 (Messaging Device Path) SubType: 1 (ATAPI)	Ata (<i>Controller,Drive,LUN</i>) Ata (<i>LUN</i>) (Display only) The <i>Controller</i> is either an integer with a value of 0 or 1 or else the keyword Primary (0) or Secondary (1). It is required. The <i>Drive</i> is either an integer with the value of 0 or 1 or else the keyword Master (0) or Slave (1). It is required. The <i>LUN</i> is a 16-bit integer. It is required.
Type: 3 (Messaging Device Path) SubType: 2 (SCSI)	Scsi (<i>PUN,LUN</i>) The <i>PUN</i> is an integer between 0 and 65535 and is required. The <i>LUN</i> is an integer between 0 and 65535 and is required.
Type: 3 (Messaging Device Path) SubType: 3 (Fibre Channel)	Fibre (<i>WWN,LUN</i>) The <i>WWN</i> is a 64-bit unsigned integer and is required. The <i>LUN</i> is a 64-bit unsigned integer and is required.

Device Node Type/SubType/Other	Description
Type: 3 (Messaging Device Path) SubType: 21 (Fibre Channel Ex)	FibreEx (<i>WWN,LUN</i>) The <i>WWN</i> is an 8 byte array that is displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e., on the right), and is required. The <i>LUN</i> is an 8 byte array that is displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e., on the right), and is required.
Type: 3 (Messaging Device Path) SubType: 4 (1394)	I1394 (<i>GUID</i>) The <i>GUID</i> is a GUID and is required.
Type: 3 (Messaging Device Path) SubType: 5 (USB)	USB (<i>Port,Interface</i>) The <i>Port</i> is an integer between 0 and 255 and is required. The <i>Interface</i> is an integer between 0 and 255 and is required.
Type: 3 (Messaging Device Path) SubType: 6 (I2O)	I2O (<i>TID</i>) The <i>TID</i> is an integer and is required.
Type: 3 (Messaging Device Path) SubType: 9 (Infiniband)	Infiniband (<i>Flags, Guid, ServiceId, TargetId, DeviceId</i>) <i>Flags</i> is an integer. <i>Guid</i> is a guid.. <i>ServiceId, TargetId</i> and <i>DeviceId</i> are 64-bit unsigned integers. All fields are required.
Type: 3 (Messaging Device Path) SubType: 10 (Vendor)	VenMsg (<i>Guid, Data</i>) The <i>Guid</i> is a GUID and is required. The <i>Data</i> is a Hex Dump and is option. The default value is zero bytes.
Type: 3 (Messaging Device Path) SubType: 10 (Vendor) GUID=EFI_PC_ANSI_GUID	VenPcAnsi ()
Type: 3 (Messaging Device Path) SubType: 10 (Vendor) GUID=EFI_VT_100_GIUD	VenVt100 ()
Type: 3 (Messaging Device Path) SubType: 10 (Vendor) GUID=EFI_VT_100_PLUS_GUID	VenVt100Plus ()
Type: 3 (Messaging Device Path) SubType: 10 (Vendor) GUID=EFI_VT_UTF8_GUID	VenUtf8 ()
Type: 3 (Messaging Device Path) SubType: 10 (Vendor) GUID=DEVICE_PATH_MESSAGING_UART_FLOW_CONTROL	UartFlowCtrl (<i>Value</i>) The <i>Value</i> is either an integer with the value 0, 1 or 2 or the keywords XonXoff (2) or Hardware (1) or None (0).

Device Node Type/SubType/ Other	Description
Type: 3 (Messaging Device Path) SubType: 10 (Serial Attached SCSI) Vendor GUID: d487ddb4-008b-11d9-afdc-001083ffca4d	<p>SAS(<i>Address, LUN, RTP, SASSATA, Location, Connect, DriveBay, Reserved</i>)</p> <p>The <i>Address</i> is a 64-bit unsigned integer representing the SAS Address and is required.</p> <p>The <i>LUN</i> is a 64-bit unsigned integer representing the Logical Unit Number and is optional. The default value is 0.</p> <p>The <i>RTP</i> is a 16-bit unsigned integer representing the Relative Target Port and is optional. The default value is 0.</p> <p>The <i>SASSATA</i> is a keyword SAS or SATA or NoTopology or an unsigned 16-bit integer and is optional. The default is NoTopology. If NoTopology or an integer are specified, then <i>Location, Connect</i> and <i>DriveBay</i> are prohibited. If SAS or SATA is specified, then <i>Location</i> and <i>Connect</i> are required, but <i>DriveBay</i> is optional. If an integer is specified, then the topology information is filled with the integer value.</p> <p>The <i>Location</i> is an integer between 0 and 1 or else the keyword Internal (0) or External (1) and is optional. If <i>SASSATA</i> is an integer or NoTopology, it is prohibited. The default value is 0.</p> <p>The <i>Connect</i> is an integer between 0 and 3 or else the keyword Direct (0) or Expanded (1) and is optional. If <i>SASSATA</i> is an integer or NoTopology, it is prohibited. The default value is 0.</p> <p>The <i>DriveBay</i> is an integer between 1 and 256 and is optional unless <i>SASSATA</i> is an integer or NoTopology, in which case it is prohibited.</p> <p>The <i>Reserved</i> field is an integer and is optional. The default value is 0.</p>
Type: 3 (Messaging Device Path) SubType: 10 (Vendor) GUID=EFI_DEBUGPORT_PROTOCOL_GUID	<p>DebugPort()</p>
Type: 3 (Messaging Device Path) SubType: 11 (MAC Address)	<p>MAC(<i>MacAddr, IfType</i>)</p> <p>The <i>MacAddr</i> is a Hex Dump and is required. If <i>IfType</i> is 0 or 1, then the <i>MacAddr</i> must be exactly six bytes.</p> <p>The <i>IfType</i> is an integer from 0-255 and is optional. The default is zero.</p>

Device Node Type/SubType/ Other	Description
Type: 3 (Messaging Device Path) SubType: 12 (IPv4)	<p>IPv4(<i>Remotelp</i>, <i>Protocol</i>, <i>Type</i>, <i>Locallp</i>, <i>GatewayIPAddress</i>, <i>SubnetMask</i>) IPv4(<i>Remotelp</i>) (Display Only)</p> <p>The <i>Remotelp</i> is an IP Address and is required. The <i>Protocol</i> is an integer between 0 and 255 or else the keyword UDP (17) or TCP (6). The default value is UDP. The <i>Type</i> is a keyword, either Static (1) or DHCP (0). It is optional. The default value is DHCP. The <i>Locallp</i> is an IP Address and is optional. The default value is all zeroes. The <i>GatewayIPAddress</i> is an IP Address and is optional. The default value is all zeroes. The <i>SubnetMask</i> is an IP Address and is optional. The default value is all zeroes.</p>
Type: 3 (Messaging Device Path) SubType: 13 (IPv6)	<p>IPv6(<i>Remotelp</i>, <i>Protocol</i>, <i>IPAddressOrigin</i>, <i>Locallp</i>, <i>GatewayIPAddress</i>, <i>SubnetMask</i>) IPv6(<i>Remotelp</i>) (Display Only)</p> <p>The <i>Remotelp</i> is an IPv6 Address and is required. The <i>Protocol</i> is an integer between 0 and 255 or else the keyword UDP (17) or TCP (6). The default value is UDP. The <i>IPAddressOrigin</i> is a keyword, could be Static (0), StatelessAutoConfigure (1), or StatefulAutoConfigure (2). The <i>Locallp</i> is the IPv6 Address and is optional. The default value is all zeroes. The <i>GatewayIPAddress</i> is an IP Address. The <i>PrefixLength</i> is the prefix length of the Local IPv6 Address. The <i>GatewayIPAddress</i> is the IPv6 Address of the Gateway.</p>
Type: 3 (Messaging Device Path) SubType: 14 (UART)	<p>Uart(<i>Baud</i>, <i>DataBits</i>, <i>Parity</i>, <i>StopBits</i>)</p> <p>The <i>Baud</i> is a 64-bit integer and is optional. The default value is 115200. The <i>DataBits</i> is an integer from 0 to 255 and is optional. The default value is 8. The <i>Parity</i> is either an integer from 0-255 or else a keyword and should be D (0), N (1), E (2), O (3), M (4) or S (5). It is optional. The default value is 0. The <i>StopBits</i> is a either an integer from 0-255 or else a keyword and should be D (0), 1 (1), 1.5 (2), 2 (3). It is optional. The default value is 0.</p>

Device Node Type/SubType/ Other	Description
Type: 3 (Messaging Device Path) SubType: 15 (USB Class)	<p>UsbClass(<i>VID,PID,Class,SubClass,Protocol</i>)</p> <p>The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>Class</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>SubClass</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p>
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 1	<p>UsbAudio(<i>VID,PID,SubClass,Protocol</i>)</p> <p>The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>SubClass</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p>
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 2	<p>UsbCDCControl(<i>VID,PID,SubClass,Protocol</i>)</p> <p>The <i>VID</i> is an optional integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>PID</i> is an optional integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>SubClass</i> is an optional integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>Protocol</i> is an optional integer between 0 and 255 and is optional. The default value is 0xFF.</p>
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 3	<p>UsbHID(<i>VID,PID,SubClass,Protocol</i>)</p> <p>The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>SubClass</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p>

Device Node Type/SubType/ Other	Description
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 6	<p>UsbImage(<i>VID,PID,SubClass,Protocol</i>)</p> <p>The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>SubClass</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p>
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 7	<p>UsbPrinter(<i>VID,PID,SubClass,Protocol</i>)</p> <p>The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>SubClass</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p>
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 8	<p>UsbMassStorage(<i>VID,PID,SubClass,Protocol</i>)</p> <p>The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>SubClass</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p>
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 9	<p>UsbHub(<i>VID,PID,SubClass,Protocol</i>)</p> <p>The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>SubClass</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p>

Device Node Type/SubType/ Other	Description
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 10	<p>UsbCDCData(<i>VID,PID,SubClass,Protocol</i>)</p> <p>The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>SubClass</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p>
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 11	<p>UsbSmartCard(<i>VID,PID,SubClass,Protocol</i>)</p> <p>The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF.</p> <p>The <i>SubClass</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p> <p>The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.</p>

Device Node Type/SubType/Other	Description
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 224	UsbWireless (<i>VID,PID,SubClass,Protocol</i>) The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF. The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF. The <i>SubClass</i> is an integer between 0 and 255 and is optional. The default value is 0xFF. The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 254 SubClass: 1	UsbDeviceFirmwareUpdate (<i>VID,PID,Protocol</i>) The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF. The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF. The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 254 SubClass: 2	UsblrdaBridge (<i>VID,PID,Protocol</i>) The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF. The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF. The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.
Type: 3 (Messaging Device Path) SubType: 15 (USB Class) Class 254 SubClass: 3	UsbTestAndMeasurement (<i>VID,PID,Protocol</i>) The <i>VID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF. The <i>PID</i> is an integer between 0 and 65535 and is optional. The default value is 0xFFFF. The <i>Protocol</i> is an integer between 0 and 255 and is optional. The default value is 0xFF.
Type: 3 (Messaging Device Path) SubType: 16 (USB WWID Class)	UsbWwid (<i>VID,PID,InterfaceNumber,"WWID"</i>) The <i>VID</i> is an integer between 0 and 65535 and is required. The <i>PID</i> is an integer between 0 and 65535 and is required. The <i>InterfaceNumber</i> is an integer between 0 and 255 and is required. The <i>WWID</i> is a string and is required.
Type: 3 (Messaging Device Path) SubType: 17 (Logical Unit Class)	Unit (<i>LUN</i>) The <i>LUN</i> is an integer and is required.

Unified Extensible Firmware Interface Specification

Device Node Type/SubType/ Other	Description
Type: 3 (Messaging Device Path) SubType: 18 (SATA)	<p>Sata(<i>HPN, PMPN, LUN</i>)</p> <p>The <i>HPN</i> is an integer between 0 and 65534 and is required. The <i>PMPN</i> is an integer between 0 and 65535 and is optional. If not provided, the default is 0xFFFF, which implies no port multiplier. The <i>LUN</i> is a 16-bit integer. It is required. Note that LUN is applicable to ATAPI devices only, and most ATAPI devices assume LUN=0</p>
Type: 3 (Messaging Device Path) SubType: 19 (iSCSI)	<p>iSCSI(<i>TargetName, PortalGroup, LUN, HeaderDigest, DataDigest, Authentication, Protocol</i>)</p> <p>The <i>TargetName</i> is a string and is required. The <i>PortalGroup</i> is an unsigned 16-bit integer and is required. The <i>LUN</i> is an 8 byte array that is displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e, on the right), and is required. The HeaderDigest is a keyword None or CRC32C is optional. The default is None. The DataDigest is a keyword None or CRC32C is optional. The default is None. The Authentication is a keyword None or CHAP_BI or CHAP_UNI and optional. The default is None. The Protocol defines the network protocol used by iSCSI and is optional. The default is TCP.</p>
Type: 3 (Messaging Device Path) SubType: 20 (VLAN)	<p>Vlan(<i>VlanId</i>)</p>

Device Node Type/SubType/ Other	Description
Type: 3 (Messaging Device Path) SubType: 22 (Serial Attached SCSI Ex)	<p>SasEx(<i>Address, LUN, RTP, SASSATA, Location, Connect, DriveBay</i>)</p> <p>The <i>Address</i> is an 8 byte array that is displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e., on the right), and is required.</p> <p>The <i>LUN</i> is an 8 byte array that is displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e., on the right), and is optional. The default value is 0.</p> <p>The <i>RTP</i> is a 16-bit unsigned integer representing the Relative Target Port and is optional. The default value is 0.</p> <p>The <i>SASSATA</i> is a keyword SAS or SATA or NoTopology or an unsigned 16-bit integer and is optional. The default is NoTopology. If NoTopology or an integer are specified, then <i>Location</i>, <i>Connect</i> and <i>DriveBay</i> are prohibited. If SAS or SATA is specified, then <i>Location</i> and <i>Connect</i> are required, but <i>DriveBay</i> is optional. If an integer is specified, then the topology information is filled with the integer value.</p> <p>The <i>Location</i> is an integer between 0 and 1 or else the keyword Internal (0) or External (1) and is optional. If <i>SASSATA</i> is an integer or NoTopology, it is prohibited. The default value is 0.</p> <p>The <i>Connect</i> is an integer between 0 and 3 or else the keyword Direct (0) or Expanded (1) and is optional. If <i>SASSATA</i> is an integer or NoTopology, it is prohibited. The default value is 0.</p> <p>The <i>DriveBay</i> is an integer between 1 and 256 and is optional unless <i>SASSATA</i> is an integer or NoTopology, in which case it is prohibited.</p>
Type: 3 (Messaging Device Path) SubType: 23 (NVM Express Namespace)	<p>NVMe(<i>NSID, EUI</i>)</p> <p>The <i>NSID</i> is a namespace identifier that is displayed in hexadecimal format with an integer value between 0 and 0xFFFFFFFF.</p> <p>The <i>EUI</i> is the IEEE Extended Unique Identifier (EUI-64) that is displayed in hexadecimal format represented as a set of octets separated by dashes (hexadecimal notation), e.g., FF-FF-FF-FF-FF-FF-FF-FF-FF.</p>
Type: 3 (Messaging Device Path) SubType: 24 (URI)	<p>Uri(<i>Uri</i>)</p> <p>The <i>Uri</i> is optional.</p>
Type: 3 (Messaging Device Path) SubType: 25 (Universal Flash Storage)	<p>UFS(<i>PUN, LUN</i>)</p> <p>The <i>PUN</i> is 0 for current UFS2.0 spec. For future UFS specs which support multiple devices on a UFS port, it would reflect the device ID on the UFS port.</p> <p>The <i>LUN</i> is 0-7 for common LUNs or 81h, D0h, B0h and C4h for well-known LUNs supported by UFS.</p>
Type: 3 (Messaging Device Path) SubType: 26 (SD)	<p>SD(<i>Slot Number</i>)</p> <p><i>SlotNumber</i> is an integer. It is optional and has a default value of 0.</p>
Type: 3 (Messaging Device Path) SubType: 27 (Bluetooth)	<p>Bluetooth(<i>BD_ADDR</i>)</p> <p><i>BD_ADDR</i> is HEX dump of 48-bit Bluetooth device address.</p>

Unified Extensible Firmware Interface Specification

Device Node Type/SubType/Other	Description
Type: 3 (Messaging Device Path) SubType: 28 (Wi-Fi)	Wi-Fi(SSID) The <i>SSID</i> is a string and is required.
Type: 3 (Messaging Device Path) SubType: 29 (eMMC)	eMMC(SlotNumber) SlotNumber is an integer. It is optional and has a default value of 0.
Type: 4 (Media Device Path) (when subtype is not recognized)	MediaPath(subtype, data) The <i>subtype</i> is an integer from 0-255 and is required. The <i>data</i> is a hex dump.
Type: 4 (Media Device Path) SubType: 1 (Hard Drive)	HD(Partition, Type, Signature, Start, Size) HD(Partition, Type, Signature) (Display Only) The <i>Partition</i> is an integer representing the partition number. It is optional and the default is 0. If <i>Partition</i> is 0, then <i>Start</i> and <i>Size</i> are prohibited. The <i>Type</i> is an integer between 0-255 or else the keyword MBR (1) or GPT (2). The type is optional and the default is 2. The <i>Signature</i> is an integer if <i>Type</i> is 1 or else GUID if <i>Type</i> is 2. The signature is required. The <i>Start</i> is a 64-bit unsigned integer. It is prohibited if <i>Partition</i> is 0. Otherwise it is required. The <i>Size</i> is a 64-bit unsigned integer. It is prohibited if <i>Partition</i> is 0. Otherwise it is required.
Type: 4 (Media Device Path) SubType: 2 (CD-ROM)	CDROM(Entry, Start, Size) CDROM(Entry) (Display Only) The <i>Entry</i> is an integer representing the Boot Entry from the Boot Catalog. It is optional and the default is 0. The <i>Start</i> is a 64-bit integer and is required. The <i>Size</i> is a 64-bit integer and is required.
Type: 4 (Media Device Path) SubType: 3 (Vendor)	VenMedia(GUID, Data) The <i>Guid</i> is a GUID and is required. The <i>Data</i> is a Hex Dump and is option. The default value is zero bytes.
Type: 4 (Media Device Path) SubType: 4 (File Path)	String The <i>String</i> is the file path and is a string.
Type: 4 (Media Device Path) SubType: 5 (Media Protocol)	Media(Guid) The <i>Guid</i> is a GUID and is required.
Type: 4 (Media Device Path) SubType: 6 (PIWG Firmware File)	Contents are defined in the <i>UEFI PI Specification</i> .

Device Node Type/SubType/Other	Description
Type: 4 (Media Device Path) SubType: 7 (PIWG Firmware Volume)	Contents are defined in the <i>UEFI PI Specification</i> .
Type: 4 (Media Device Path) SubType: 8 (Relative Offset Range)	Offset (<i>StartingOffset,EndingOffset</i>) The <i>StartingOffset</i> is an unsigned 64-bit integer. The <i>EndingOffset</i> is an unsigned 64-bit integer.
Type: 4 (Media Device Path) SubType: 9 (RAM Disk)	RamDisk (<i>StartingAddress,EndingAddress,DiskInstance,DiskTypeGuid</i>) The <i>StartingAddress</i> and <i>EndingAddress</i> are both 64-bit integers and are both required. The <i>DiskInstance</i> is a 16-bit integer and is optional. The default value is 0. The <i>DiskTypeGuid</i> is a GUID and is required.
Type: 4 (Media Device Path) SubType: 9 (RAM Disk) Disk Type GUID= EFI_VIRTUAL_DISK_GUID	VirtualDisk (<i>StartingAddress,EndingAddress,DiskInstance</i>) The <i>StartingAddress</i> and <i>EndingAddress</i> are both 64-bit integers and are both required. The <i>DiskInstance</i> is a 16-bit integer and is optional. The default value is 0.
Type: 4 (Media Device Path) SubType: 9 (RAM Disk) Disk Type GUID= EFI_VIRTUAL_CD_GUID	VirtualCD (<i>StartingAddress,EndingAddress,DiskInstance</i>) The <i>StartingAddress</i> and <i>EndingAddress</i> are both 64-bit integers and are both required. The <i>DiskInstance</i> is a 16-bit integer and is optional. The default value is 0.
Type: 4 (Media Device Path) SubType: 9 (RAM Disk) Disk Type GUID= EFI_PERSISTENT_VIRTUAL_DISK_GUID	PersistentVirtualDisk (<i>StartingAddress,EndingAddress,DiskInstance</i>) The <i>StartingAddress</i> and <i>EndingAddress</i> are both 64-bit integers and are both required. The <i>DiskInstance</i> is a 16-bit integer and is optional. The default value is 0.
Type: 4 (Media Device Path) SubType: 9 (RAM Disk) Disk Type GUID= EFI_PERSISTENT_VIRTUAL_CD_GUID	PersistentVirtualCD (<i>StartingAddress,EndingAddress,DiskInstance</i>) The <i>StartingAddress</i> and <i>EndingAddress</i> are both 64-bit integers and are both required. The <i>DiskInstance</i> is a 16-bit integer and is optional. The default value is 0.
Type: 5 (Media Device Path) (when subtype is not recognized)	BbsPath (<i>subtype, data</i>) The <i>subtype</i> is an integer from 0-255. The <i>data</i> is a hex dump.

Device Node Type/SubType/ Other	Description
Type: 5 (BIOS Boot Specification Device Path) SubType: 1 (BBS 1.01)	BBS (<i>Type,Id,Flags</i>) BBS (<i>Type, Id</i>) (Display Only) The <i>Type</i> is an integer from 0-65535 or else one of the following keywords: Floppy (1), HD (2), CDROM (3), PCMCIA (4), USB (5), Network (6). It is required. The <i>Id</i> is a string and is required. The <i>Flags</i> are an integer and are optional. The default value is 0.

9.6.2 Device Path to Text Protocol

EFI_DEVICE_PATH_TO_TEXT_PROTOCOL

Summary

Convert device nodes and paths to text

GUID

```
#define EFI_DEVICE_PATH_TO_TEXT_PROTOCOL_GUID \
    {0x8b843e20,0x8132,0x4852, \
     {0x90,0xcc,0x55,0x1a,0x4e,0x4a,0x7f,0x1c}}
```

Protocol Interface Structure

```
typedef struct _EFI_DEVICE_PATH_TO_TEXT_PROTOCOL {
    EFI_DEVICE_PATH_TO_TEXT_NODE ConvertDeviceNodeToText;
    EFI_DEVICE_PATH_TO_TEXT_PATH ConvertDevicePathToText;
} EFI_DEVICE_PATH_TO_TEXT_PROTOCOL;
```

Parameters

ConvertDeviceNodeToText Converts a device node to text.

ConvertDevicePathToText Converts a device path to text.

Description

The **EFI_DEVICE_PATH_TO_TEXT_PROTOCOL** provides common utility functions for converting device nodes and device paths to a text representation.

EFI_DEVICE_PATH_TO_TEXT_PROTOCOL.ConvertDeviceNodeToText()

Summary

Convert a device node to its text representation.

Prototype

```
typedef
CHAR16*
(EFI_API *EFI_DEVICE_PATH_TO_TEXT_NODE) (
    IN CONST EFI_DEVICE_PATH_PROTOCOL* DeviceNode,
    IN BOOLEAN DisplayOnly,
    IN BOOLEAN AllowShortcuts
);
```

Parameters

<i>DeviceNode</i>	Points to the device node to be converted.
<i>DisplayOnly</i>	If <i>DisplayOnly</i> is TRUE , then the shorter text representation of the display node is used, where applicable. If <i>DisplayOnly</i> is FALSE , then the longer text representation of the display node is used.
<i>AllowShortcuts</i>	If <i>AllowShortcuts</i> is TRUE , then the shortcut forms of text representation for a device node can be used, where applicable.

Description

The ConvertDeviceNodeToText function converts a device node to its text representation and copies it into a newly allocated buffer.

The *DisplayOnly* parameter controls whether the longer (parseable) or shorter (display-only) form of the conversion is used.

The *AllowShortcuts* is **FALSE**, then the shortcut forms of text representation for a device node cannot be used. A shortcut form is one which uses information other than the type or subtype.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns the pointer to the allocated text representation of the device node data or else NULL if *DeviceNode* was NULL or there was insufficient memory.

EFI_DEVICE_PATH_TO_TEXT_PROTOCOL.ConvertDevicePathToText ()

Summary

Convert a device path to its text representation.

Prototype

```
typedef
CHAR16*
(EFI_API *EFI_DEVICE_PATH_TO_TEXT_PATH) (
    IN CONST EFI_DEVICE_PATH_PROTOCOL    *DevicePath,
    IN BOOLEAN                           DisplayOnly,
    IN BOOLEAN                           AllowShortcuts
);
```

Parameters

<i>DeviceNode</i>	Points to the device path to be converted.
<i>DisplayOnly</i>	If <i>DisplayOnly</i> is TRUE, then the shorter text representation of the display node is used, where applicable. If <i>DisplayOnly</i> is FALSE, then the longer text representation of the display node is used.
<i>AllowShortcuts</i>	The <i>AllowShortcuts</i> is FALSE, then the shortcut forms of text representation for a device node cannot be used.

Description

This function converts a device path into its text representation and copies it into an allocated buffer.

The *DisplayOnly* parameter controls whether the longer (parseable) or shorter (display-only) form of the conversion is used.

The *AllowShortcuts* is **FALSE**, then the shortcut forms of text representation for a device node cannot be used. A shortcut form is one which uses information other than the type or subtype.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns a pointer to the allocated text representation of the device node or NULL if *DevicePath* was NULL or there was insufficient memory.

9.6.3 Device Path from Text Protocol

EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL

Summary

Convert text to device paths and device nodes.

GUID

```
#define EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL_GUID \
  {0x5c99a21,0xc70f,0x4ad2,\
   {0x8a,0x5f,0x35,0xdf,0x33,0x43,0xf5, 0x1e}}
```

Protocol Interface Structure

```
typedef struct _EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL {
  EFI_DEVICE_PATH_FROM_TEXT_NODE ConvertTextToDeviceNode;
  EFI_DEVICE_PATH_FROM_TEXT_PATH ConvertTextToDevicePath;
} EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL;
```

Parameters

ConvertTextToDeviceNode Converts text to a device node.

ConvertTextToDevicePath Converts text to a device path.

Description

The **EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL** provides common utilities for converting text to device paths and device nodes.

EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL.ConvertTextToDeviceNode()

Summary

Convert text to the binary representation of a device node.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_FROM_TEXT_NODE) (
    IN CONST CHAR16* TextDeviceNode
);
```

Parameters

TextDeviceNode *TextDeviceNode* points to the text representation of a device node. Conversion starts with the first character and continues until the first non-device node character.

Description

This function converts text to its binary device node representation and copies it into an allocated buffer.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns a pointer to the EFI device node or NULL if *TextDeviceNode* is NULL or there was insufficient memory.

EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL.ConvertTextToDevicePath()

Summary

Convert a text to its binary device path representation.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFI_API *EFI_DEVICE_PATH_FROM_TEXT_PATH) (
    IN CONST CHAR16* TextDevicePath
);
```

Parameters

TextDevicePath *TextDevicePath* points to the text representation of a device path. Conversion starts with the first character and continues until the first non-device path character.

Description

This function converts text to its binary device path representation and copies it into an allocated buffer.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in [Section 9.2](#).

Returns

This function returns a pointer to the allocated device path or NULL if *TextDevicePath* is NULL or there was insufficient memory.

Protocols — UEFI Driver Model

EFI drivers that follow the *UEFI Driver Model* are not allowed to search for controllers to manage. When a specific controller is needed, the EFI boot service `EFI_BOOT_SERVICES.ConnectController()` is used along with the `EFI_DRIVER_BINDING_PROTOCOL` services to identify the best drivers for a controller. Once `ConnectController()` has identified the best drivers for a controller, the start service in the `EFI_DRIVER_BINDING_PROTOCOL` is used by `ConnectController()` to start each driver on the controller. Once a controller is no longer needed, it can be released with the EFI boot service `EFI_BOOT_SERVICES.DisconnectController()`. `DisconnectController()` calls the stop service in each `EFI_DRIVER_BINDING_PROTOCOL` to stop the controller.

The driver initialization routine of an UEFI driver is not allowed to touch any device hardware. Instead, it just installs an instance of the `EFI_DRIVER_BINDING_PROTOCOL` on the `ImageHandle` of the UEFI driver. The test to determine if a driver supports a given controller must be performed in as little time as possible without causing any side effects on any of the controllers it is testing. As a result, most of the controller initialization code is present in the start and stop services of the `EFI_DRIVER_BINDING_PROTOCOL`.

10.1 EFI Driver Binding Protocol

This section provides a detailed description of the `EFI_DRIVER_BINDING_PROTOCOL`. This protocol is produced by every driver that follows the *UEFI Driver Model*, and it is the central component that allows drivers and controllers to be managed. It provides a service to test if a specific controller is supported by a driver, a service to start managing a controller, and a service to stop managing a controller. These services apply equally to drivers for both bus controllers and device controllers.

EFI_DRIVER_BINDING_PROTOCOL

Summary

Provides the services required to determine if a driver supports a given controller. If a controller is supported, then it also provides routines to start and stop the controller.

GUID

```
#define EFI_DRIVER_BINDING_PROTOCOL_GUID \
{0x18A031AB,0xB443,0x4D1A,\
 0xA5,0xC0,0x0C,0x09,0x26,0x1E,0x9F,0x71}
```

Protocol Interface Structure

```
typedef struct _EFI_DRIVER_BINDING_PROTOCOL {
  EFI_DRIVER_BINDING_PROTOCOL_SUPPORTED Supported;
```

```

EFI_DRIVER_BINDING_PROTOCOL_START      Start;
EFI_DRIVER_BINDING_PROTOCOL_STOP      Stop;
UINT32                                 Version;
EFI_HANDLE                             ImageHandle;
EFI_HANDLE                             DriverBindingHandle;
} EFI_DRIVER_BINDING_PROTOCOL;

```

Parameters

<i>Supported</i>	Tests to see if this driver supports a given controller. This service is called by the EFI boot service EFI_BOOT_SERVICES.ConnectController() . In order to make drivers as small as possible, there are a few calling restrictions for this service. ConnectController() must follow these calling restrictions. If any other agent wishes to call Supported() it must also follow these calling restrictions. See the Supported() function description.
<i>Start</i>	Starts a controller using this driver. This service is called by the EFI boot service ConnectController() . In order to make drivers as small as possible, there are a few calling restrictions for this service. ConnectController() must follow these calling restrictions. If any other agent wishes to call Start() it must also follow these calling restrictions. See the Start() function description.
<i>Stop</i>	Stops a controller using this driver. This service is called by the EFI boot service EFI_BOOT_SERVICES.DisconnectController() . In order to make drivers as small as possible, there are a few calling restrictions for this service. DisconnectController() must follow these calling restrictions. If any other agent wishes to call Stop() it must also follow these calling restrictions. See the Stop() function description.
<i>Version</i>	The version number of the UEFI driver that produced the EFI_DRIVER_BINDING_PROTOCOL . This field is used by the EFI boot service ConnectController() to determine the order that driver's Supported() service will be used when a controller needs to be started. EFI Driver Binding Protocol instances with higher <i>Version</i> values will be used before ones with lower <i>Version</i> values. The <i>Version</i> values of <i>0x0-0x0f</i> and <i>0xffffffff0-0xffffffff</i> are reserved for platform/OEM specific drivers. The <i>Version</i> values of <i>0x10-0xfffffffef</i> are reserved for IHV-developed drivers.
<i>ImageHandle</i>	The image handle of the UEFI driver that produced this instance of the EFI_DRIVER_BINDING_PROTOCOL .
<i>DriverBindingHandle</i>	The handle on which this instance of the EFI_DRIVER_BINDING_PROTOCOL is installed. In most cases, this is the same handle as <i>ImageHandle</i> . However, for UEFI drivers that produce more than one instance of the

EFI_DRIVER_BINDING_PROTOCOL, this value may not be the same as *ImageHandle*.

Description

The **EFI_DRIVER_BINDING_PROTOCOL** provides a service to determine if a driver supports a given controller. If a controller is supported, then it also provides services to start and stop the controller. All UEFI drivers are required to be reentrant so they can manage one or more controllers. This requires that drivers not use global variables to store device context. Instead, they must allocate a separate context structure per controller that the driver is managing. Bus drivers must support starting and stopping the same bus multiple times, and they must also support starting and stopping all of their children, or just a subset of their children.

EFI_DRIVER_BINDING_PROTOCOL.Supported()

Summary

Tests to see if this driver supports a given controller. If a child device is provided, it further tests to see if this driver supports creating a handle for the specified child device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_BINDING_PROTOCOL_SUPPORTED) (
    IN  EFI_DRIVER_BINDING_PROTOCOL  *This,
    IN  EFI_HANDLE                   ControllerHandle,
    IN  EFI_DEVICE_PATH_PROTOCOL     *RemainingDevicePath  OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_DRIVER_BINDING_PROTOCOL instance.
<i>ControllerHandle</i>	The handle of the controller to test. This handle must support a protocol interface that supplies an I/O abstraction to the driver. Sometimes just the presence of this I/O abstraction is enough for the driver to determine if it supports <i>ControllerHandle</i> . Sometimes, the driver may use the services of the I/O abstraction to determine if this driver supports <i>ControllerHandle</i> .
<i>RemainingDevicePath</i>	A pointer to the remaining portion of a device path. For bus drivers, if this parameter is not NULL , then the bus driver must determine if the bus controller specified by <i>ControllerHandle</i> and the child controller specified by <i>RemainingDevicePath</i> are both supported by this bus driver.

Description

This function checks to see if the driver specified by *This* supports the device specified by *ControllerHandle*. Drivers will typically use the device path attached to *ControllerHandle* and/or the services from the bus I/O abstraction attached to *ControllerHandle* to determine if the driver supports *ControllerHandle*. This function may be called many times during platform initialization. In order to reduce boot times, the tests performed by this function must be very small, and take as little time as possible to execute. This function must not change the state of any hardware devices, and this function must be aware that the device specified by *ControllerHandle* may already be managed by the same driver or a different driver. This function must match its calls to [EFI_BOOT_SERVICES.AllocatePages\(\)](#) with [EFI_BOOT_SERVICES.FreePages\(\)](#), [EFI_BOOT_SERVICES.AllocatePool\(\)](#) with [EFI_BOOT_SERVICES.FreePool\(\)](#), and [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) with [EFI_BOOT_SERVICES.CloseProtocol\(\)](#). Since *ControllerHandle* may have been previously started by the same driver, if a protocol is already in the opened state, then it must not be

closed with **CloseProtocol()**. This is required to guarantee the state of *ControllerHandle* is not modified by this function.

If any of the protocol interfaces on the device specified by *ControllerHandle* that are required by the driver specified by *This* are already open for exclusive access by a different driver or application, then **EFI_ACCESS_DENIED** is returned.

If any of the protocol interfaces on the device specified by *ControllerHandle* that are required by the driver specified by *This* are already opened by the same driver, then **EFI_ALREADY_STARTED** is returned. However, if the driver specified by *This* is a bus driver, then it is not an error, and the bus driver should continue with its test of *ControllerHandle* and *RemainingDevicePath*. This allows a bus driver to create one child handle on the first call to **Supported()** and **Start()**, and create additional child handles on additional calls to **Supported()** and **Start()**. This also allows a bus driver to create no child handle on the first call to **Supported()** and **Start()** by specifying an End of Device Path Node *RemainingDevicePath*, and create additional child handles on additional calls to **Supported()** and **Start()**.

If *ControllerHandle* is not supported by *This*, then **EFI_UNSUPPORTED** is returned.

If *This* is a bus driver that creates child handles with an **EFI_DEVICE_PATH_PROTOCOL**, then *ControllerHandle* must support the **EFI_DEVICE_PATH_PROTOCOL**. If it does not, then **EFI_UNSUPPORTED** is returned.

If *ControllerHandle* is supported by *This*, and *This* is a device driver, then **EFI_SUCCESS** is returned.

If *ControllerHandle* is supported by *This*, and *This* is a bus driver, and *RemainingDevicePath* is **NULL** or the first Device Path Node is the End of Device Path Node, then **EFI_SUCCESS** is returned.

If *ControllerHandle* is supported by *This*, and *This* is a bus driver, and *RemainingDevicePath* is not **NULL**, then *RemainingDevicePath* must be analyzed. If the first node of *RemainingDevicePath* is the End of Device Path Node or an EFI Device Path node that the bus driver recognizes and supports, then **EFI_SUCCESS** is returned. Otherwise, **EFI_UNSUPPORTED** is returned.

The **Supported()** function is designed to be invoked from the EFI boot service **EFI_BOOT_SERVICES.ConnectController()**. As a result, much of the error checking on the parameters to **Supported()** has been moved into this common boot service. It is legal to call **Supported()** from other locations, but the following calling restrictions must be followed or the system behavior will not be deterministic.

ControllerHandle must be a valid **EFI_HANDLE**. If *RemainingDevicePath* is not **NULL**, then it must be a pointer to a naturally aligned **EFI_DEVICE_PATH_PROTOCOL**.

Status Codes Returned

EFI_SUCCESS	The device specified by <i>ControllerHandle</i> and <i>RemainingDevicePath</i> is supported by the driver specified by <i>This</i> .
EFI_ALREADY_STARTED	The device specified by <i>ControllerHandle</i> and <i>RemainingDevicePath</i> is already being managed by the driver specified by <i>This</i> .
EFI_ACCESS_DENIED	The device specified by <i>ControllerHandle</i> and <i>RemainingDevicePath</i> is already being managed by a different driver or an application that requires exclusive access.
EFI_UNSUPPORTED	The device specified by <i>ControllerHandle</i> and <i>RemainingDevicePath</i> is not supported by the driver specified by <i>This</i> .

Examples

```

extern EFI_GUID          gEfiDriverBindingProtocolGuid;
EFI_HANDLE              DriverImageHandle;
EFI_HANDLE              ControllerHandle;
EFI_DRIVER_BINDING_PROTOCOL *DriverBinding;
EFI_DEVICE_PATH_PROTOCOL *RemainingDevicePath;

//
// Use the DriverImageHandle to get the Driver Binding Protocol instance
//
Status = gBS->OpenProtocol (
    DriverImageHandle,
    &gEfiDriverBindingProtocolGuid,
    &DriverBinding,
    DriverImageHandle,
    NULL,
    EFI_OPEN_PROTOCOL_GET_PROTOCOL
);
if (EFI_ERROR (Status)) {
    return Status;
}

//
// EXAMPLE #1
//
// Use the Driver Binding Protocol instance to test to see if the
// driver specified by DriverImageHandle supports the controller
// specified by ControllerHandle
//
Status = DriverBinding->Supported (
    DriverBinding,
    ControllerHandle,
    NULL
);

return Status;

//
// EXAMPLE #2

```

```

//
// The RemainingDevicePath parameter can be used to initialize only
// the minimum devices required to boot. For example, maybe we only
// want to initialize 1 hard disk on a SCSI channel. If DriverImageHandle
// is a SCSI Bus Driver, and ControllerHandle is a SCSI Controller, and
// we only want to create a child handle for PUN=3 and LUN=0, then the
// RemainingDevicePath would be SCSI(3,0)/END. The following example
// would return EFI_SUCCESS if the SCSI driver supports creating the
// child handle for PUN=3, LUN=0. Otherwise it would return an error.
//
Status = DriverBinding->Supported (
    DriverBinding,
    ControllerHandle,
    RemainingDevicePath
);

return Status;

```

Pseudo Code

Listed below are the algorithms for the [Supported\(\)](#) function for three different types of drivers. How the [Start\(\)](#) function of a driver is implemented can affect how the [Supported\(\)](#) function is implemented. All of the services in the [EFI DRIVER BINDING PROTOCOL](#) need to work together to make sure that all resources opened or allocated in [Supported\(\)](#) and [Start\(\)](#) are released in [Stop\(\)](#).

The first algorithm is a simple device driver that does not create any additional handles. It only attaches one or more protocols to an existing handle. The second is a bus driver that always creates all of its child handles on the first call to [Start\(\)](#). The third is a more advanced bus driver that can either create one child handles at a time on successive calls to [Start\(\)](#), or it can create all of its child handles or all of the remaining child handles in a single call to [Start\(\)](#).

Device Driver:

1. Ignore the parameter *RemainingDevicePath*.
2. Open all required protocols with [EFI_BOOT_SERVICES.OpenProtocol\(\)](#). A standard driver should use an *Attribute* of [EFI_OPEN_PROTOCOL_BY_DRIVER](#). If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an *Attribute* of [EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE](#).
3. If any of the calls to [OpenProtocol\(\)](#) in (2) returned an error, then close all of the protocols opened in (2) with [EFI_BOOT_SERVICES.CloseProtocol\(\)](#), and return the status code from the call to [OpenProtocol\(\)](#) that returned an error.
4. Use the protocol instances opened in (2) to test to see if this driver supports the controller. Sometimes, just the presence of the protocols is enough of a test. Other times, the services of the protocols opened in (2) are used to further check the identity of the controller. If any of these tests fails, then close all the protocols opened in (2) with [CloseProtocol\(\)](#) and return [EFI_UNSUPPORTED](#).
5. Close all protocols opened in (2) with [CloseProtocol\(\)](#).
6. Return [EFI_SUCCESS](#).

Bus Driver that creates all of its child handles on the first call to Start():

1. Check the contents of the first Device Path Node of *RemainingDevicePath* to make sure it is the End of Device Path Node or a legal Device Path Node for this bus driver's children. If it is not, then return [EFI_UNSUPPORTED](#).

2. Open all required protocols with [EFI_BOOT_SERVICES.OpenProtocol\(\)](#). A standard driver should use an *Attribute* of **EFI_OPEN_PROTOCOL_BY_DRIVER**. If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an *Attribute* of **EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE**.
3. If any of the calls to **OpenProtocol()** in (2) returned an error, then close all of the protocols opened in (2) with [EFI_BOOT_SERVICES.CloseProtocol\(\)](#), and return the status code from the call to **OpenProtocol()** that returned an error.
4. Use the protocol instances opened in (2) to test to see if this driver supports the controller. Sometimes, just the presence of the protocols is enough of a test. Other times, the services of the protocols opened in (2) are used to further check the identity of the controller. If any of these tests fails, then close all the protocols opened in (2) with **CloseProtocol()** and return **EFI_UNSUPPORTED**.
5. Close all protocols opened in (2) with **CloseProtocol()**.
6. Return **EFI_SUCCESS**.

Bus Driver that is able to create all or one of its child handles on each call to Start():

1. Check the contents of the first Device Path Node of *RemainingDevicePath* to make sure it is the End of Device Path Node or a legal Device Path Node for this bus driver’s children. If it is not, then return **EFI_UNSUPPORTED**.
2. Open all required protocols with **OpenProtocol()**. A standard driver should use an *Attribute* of **EFI_OPEN_PROTOCOL_BY_DRIVER**. If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an *Attribute* of **EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE**.
3. If any of the calls to **OpenProtocol()** in (2) failed with an error other than **EFI_ALREADY_STARTED**, then close all of the protocols opened in (2) that did not return **EFI_ALREADY_STARTED** with **CloseProtocol()**, and return the status code from the **OpenProtocol()** call that returned an error.
4. Use the protocol instances opened in (2) to test to see if this driver supports the controller. Sometimes, just the presence of the protocols is enough of a test. Other times, the services of the protocols opened in (2) are used to further check the identity of the controller. If any of these tests fails, then close all the protocols opened in (2) that did not return **EFI_ALREADY_STARTED** with **CloseProtocol()** and return **EFI_UNSUPPORTED**.
5. Close all protocols opened in (2) that did not return **EFI_ALREADY_STARTED** with **CloseProtocol()**.
6. Return **EFI_SUCCESS**.

Listed below is sample code of the [Supported\(\)](#) function of device driver for a device on the XYZ bus. The XYZ bus is abstracted with the **EFI_XYZ_IO_PROTOCOL**. Just the presence of the **EFI_XYZ_IO_PROTOCOL** on *ControllerHandle* is enough to determine if this driver supports *ControllerHandle*. The **gBS** variable is initialized in this driver’s entry point. See [Section 4](#).

```
extern EFI_GUID          gEfiXyzIoProtocol;
EFI_BOOT_SERVICES      *gBS;

EFI_STATUS
AbcSupported (
```

```

    IN EFI_DRIVER_BINDING_PROTOCOL *This,
    IN EFI_HANDLE                  ControllerHandle,
    IN EFI_DEVICE_PATH_PROTOCOL    *RemainingDevicePath OPTIONAL
)

{
    EFI_STATUS          Status;
    EFI_XYZ_IO_PROTOCOL *XYZIo;

    Status = gBS->OpenProtocol (
        ControllerHandle,
        &gEfiXYZIoProtocol,
        &XYZIo,
        This->DriverBindingHandle,
        ControllerHandle,
        EFI_OPEN_PROTOCOL_BY_DRIVER
    );
    if (EFI_ERROR (Status)) {
        return Status;
    }

    gBS->CloseProtocol (
        ControllerHandle,
        &gEfiXYZIoProtocol,
        This->DriverBindingHandle,
        ControllerHandle
    );

    return EFI_SUCCESS;
}

```

EFI_DRIVER_BINDING_PROTOCOL.Start()

Summary

Starts a device controller or a bus controller. The **Start()** and **Stop()** services of the [EFI DRIVER BINDING PROTOCOL](#) mirror each other.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_BINDING_PROTOCOL_START) (
    IN  EFI_DRIVER_BINDING_PROTOCOL *This,
    IN  EFI_HANDLE                  ControllerHandle,
    IN  EFI_DEVICE_PATH_PROTOCOL   *RemainingDevicePath  OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_DRIVER_BINDING_PROTOCOL instance.
<i>ControllerHandle</i>	The handle of the controller to start. This handle must support a protocol interface that supplies an I/O abstraction to the driver.
<i>RemainingDevicePath</i>	A pointer to the remaining portion of a device path. For a bus driver, if this parameter is NULL , then handles for all the children of <i>Controller</i> are created by this driver. If this parameter is not NULL and the first Device Path Node is not the End of Device Path Node, then only the handle for the child device specified by the first Device Path Node of <i>RemainingDevicePath</i> is created by this driver. If the first Device Path Node of <i>RemainingDevicePath</i> is the End of Device Path Node, no child handle is created by this driver.

Description

This function starts the device specified by *Controller* with the driver specified by *This*. Whatever resources are allocated in **Start()** must be freed in **Stop()**. For example, every [EFI_BOOT_SERVICES.AllocatePool\(\)](#), [EFI_BOOT_SERVICES.AllocatePages\(\)](#), [EFI_BOOT_SERVICES.OpenProtocol\(\)](#), and [EFI_BOOT_SERVICES.InstallProtocolInterface\(\)](#) in **Start()** must be matched with a [EFI_BOOT_SERVICES.FreePool\(\)](#), [EFI_BOOT_SERVICES.FreePages\(\)](#), [EFI_BOOT_SERVICES.CloseProtocol\(\)](#), and [EFI_BOOT_SERVICES.UninstallProtocolInterface\(\)](#) in **Stop()**.

If *Controller* is started, then **EFI_SUCCESS** is returned.

If *Controller* could not be started, but can potentially be repaired with configuration or repair operations using the **EFI_DRIVER_HEALTH_PROTOCOL** and this driver produced an instance of the **EFI_DRIVER_HEALTH_PROTOCOL** for *Controller*, then return **EFI_SUCCESS**.

If *Controller* cannot be started due to a device error and the driver does not produce the **EFI_DRIVER_HEALTH_PROTOCOL** for *Controller*, then return **EFI_DEVICE_ERROR**.

If the driver does not support *Controller* then **EFI_DEVICE_ERROR** is returned. This condition will only be met if **Supported()** returns **EFI_SUCCESS** and a more extensive supported check in **Start()** fails.

If there are not enough resources to start the device or bus specified by *Controller*, then **EFI_OUT_OF_RESOURCES** is returned.

If the driver specified by *This* is a device driver, then *RemainingDevicePath* is ignored.

If the driver specified by *This* is a bus driver, and *RemainingDevicePath* is **NULL**, then all of the children of *Controller* are discovered and enumerated, and a device handle is created for each child.

If the driver specified by *This* is a bus driver, and *RemainingDevicePath* is not **NULL** and begins with the End of Device Path node, then the driver must not enumerate any of the children of *Controller* nor create any child device handle. Only the controller initialization should be performed. If the driver implements **EFI_DRIVER_DIAGNOSTICS2_PROTOCOL**, **EFI_COMPONENT_NAME2_PROTOCOL**, **EFI_SERVICE_BINDING_PROTOCOL**, **EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL**, or **EFI_DRIVER_HEALTH_PROTOCOL**, the driver still should install the implemented protocols. If the driver supports **EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL**, the driver still should retrieve and process the configuration information.

If the driver specified by *This* is a bus driver that is capable of creating one child handle at a time and *RemainingDevicePath* is not **NULL** and does not begin with the End of Device Path node, then an attempt is made to create the device handle for the child device specified by *RemainingDevicePath*. Depending on the bus type, all of the child devices may need to be discovered and enumerated, but at most only the device handle for the one child specified by *RemainingDevicePath* shall be created.

The **Start()** function is designed to be invoked from the EFI boot service **EFI_BOOT_SERVICES.ConnectController()**. As a result, much of the error checking on the parameters to **Start()** has been moved into this common boot service. It is legal to call **Start()** from other locations, but the following calling restrictions must be followed or the system behavior will not be deterministic.

- *ControllerHandle* must be a valid **EFI_HANDLE**.
- If *RemainingDevicePath* is not **NULL**, then it must be a pointer to a naturally aligned **EFI_DEVICE_PATH_PROTOCOL**.
- Prior to calling **Start()**, the **Supported()** function for the driver specified by *This* must have been called with the same calling parameters, and **Supported()** must have returned **EFI_SUCCESS**.

Status Codes Returned

EFI_SUCCESS	The device was started.
EFI_SUCCESS	The device could not be started because the device needs to be configured by the user or requires a repair operation, and the driver produced the Driver Health Protocol that will return the required configuration and repair operations for this device.
EFI_DEVICE_ERROR	The driver does not produce the Driver Health Protocol and the device could not be started due to a device error.
EFI_DEVICE_ERROR	The driver produces the Driver Health Protocol, and the driver does not support the device.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

Examples

```
extern EFI_GUID                gEfiDriverBindingProtocolGuid;
EFI_HANDLE                    DriverImageHandle;
EFI_HANDLE                    ControllerHandle;
EFI_DRIVER_BINDING_PROTOCOL   *DriverBinding;
EFI_DEVICE_PATH_PROTOCOL     *RemainingDevicePath;

//
// Use the DriverImageHandle to get the Driver Binding Protocol instance
//
Status = gBS->OpenProtocol (
    DriverImageHandle,
    &gEfiDriverBindingProtocolGuid,
    &DriverBinding,
    DriverImageHandle,
    NULL,
    EFI_OPEN_PROTOCOL_GET_PROTOCOL
);
if (EFI_ERROR (Status)) {
    return Status;
}

//
// EXAMPLE #1
//
// Use the Driver Binding Protocol instance to test to see if the
// driver specified by DriverImageHandle supports the controller
// specified by ControllerHandle
//
Status = DriverBinding->Supported (
    DriverBinding,
    ControllerHandle,
    NULL
);
if (!EFI_ERROR (Status)) {
    Status = DriverBinding->Start (
        DriverBinding,
        ControllerHandle,
        NULL
    );
}
```

```

return Status;

//
// EXAMPLE #2
//
// The RemainingDevicePath parameter can be used to initialize only
// the minimum devices required to boot. For example, maybe we only
// want to initialize 1 hard disk on a SCSI channel. If DriverImageHandle
// is a SCSI Bus Driver, and ControllerHandle is a SCSI Controller, and
// we only want to create a child handle for PUN=3 and LUN=0, then the
// RemainingDevicePath would be SCSI(3,0)/END. The following example
// would return EFI_SUCCESS if the SCSI driver supports creating the
// child handle for PUN=3, LUN=0. Otherwise it would return an error.
//
Status = DriverBinding->Supported (
    DriverBinding,
    ControllerHandle,
    RemainingDevicePath
);
if (!EFI_ERROR (Status)) {
    Status = DriverBinding->Start (
        DriverBinding,
        ControllerHandle,
        RemainingDevicePath
    );
}

return Status;

```

Pseudo Code

Listed below are the algorithms for the [Start\(\)](#) function for three different types of drivers. How the [Start\(\)](#) function of a driver is implemented can affect how the [Supported\(\)](#) function is implemented. All of the services in the [EFI DRIVER BINDING PROTOCOL](#) need to work together to make sure that all resources opened or allocated in [Supported\(\)](#) and [Start\(\)](#) are released in [Stop\(\)](#).

The first algorithm is a simple device driver that does not create any additional handles. It only attaches one or more protocols to an existing handle. The second is a simple bus driver that always creates all of its child handles on the first call to [Start\(\)](#). It does not attach any additional protocols to the handle for the bus controller. The third is a more advanced bus driver that can either create one child handles at a time on successive calls to [Start\(\)](#), or it can create all of its child handles or all of the remaining child handles in a single call to [Start\(\)](#). Once again, it does not attach any additional protocols to the handle for the bus controller.

Device Driver:

1. Ignore the parameter *RemainingDevicePath*.
2. Open all required protocols with [EFI_BOOT_SERVICES.OpenProtocol\(\)](#). A standard driver should use an *Attribute* of [EFI_OPEN_PROTOCOL_BY_DRIVER](#). If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an *Attribute* of [EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE](#). It must use the same *Attribute* value that was used in [Supported\(\)](#).

3. If any of the calls to `OpenProtocol()` in (2) returned an error, then close all of the protocols opened in (2) with `EFI_BOOT_SERVICES.CloseProtocol()`, and return the status code from the call to `OpenProtocol()` that returned an error.
4. Initialize the device specified by `ControllerHandle`. If the driver does not support the device specified by `ControllerHandle`, then close all of the protocols opened in (2) with `CloseProtocol()`, and return `EFI_DEVICE_ERROR`. If the driver does support the device specified by `ControllerHandle` and an error is detected, and that error can not be resolved with the `EFI_DRIVER_HEALTH_PROTOCOL`, then close all of the protocols opened in (2) with `CloseProtocol()`, and return `EFI_DEVICE_ERROR`. If the driver does support the device specified by `ControllerHandle` and an error is detected, and that error can be resolved with the `EFI_DRIVER_HEALTH_PROTOCOL`, then produce the `EFI_DRIVER_HEALTH_PROTOCOL` for `ControllerHandle` and make sure `EFI_SUCCESS` is returned from `Start()`. In this case, depending on the type of error detected, not all of the following steps may be completed
5. Allocate and initialize all of the data structures that this driver requires to manage the device specified by `ControllerHandle`. This would include space for public protocols and space for any additional private data structures that are related to `ControllerHandle`. If an error occurs allocating the resources, then close all of the protocols opened in (2) with `CloseProtocol()`, and return `EFI_OUT_OF_RESOURCES`.
6. Install all the new protocol interfaces onto `ControllerHandle` using `EFI_BOOT_SERVICES.InstallMultipleProtocolInterfaces()`. If an error occurs, close all of the protocols opened in (1) with `CloseProtocol()`, and return the error from `InstallMultipleProtocolInterfaces()`.
7. Return `EFI_SUCCESS`.

Bus Driver that creates all of its child handles on the first call to Start():

1. Ignore the parameter `RemainingDevicePath`. with the exception that if the first Device Path Node is the End of Device Path Node, skip steps 5-8.
2. Open all required protocols with `EFI_BOOT_SERVICES.OpenProtocol()`. A standard driver should use an `Attribute` of `EFI_OPEN_PROTOCOL_BY_DRIVER`. If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an `Attribute` of `EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE`. It must use the same `Attribute` value that was used in `Supported()`.
3. If any of the calls to `OpenProtocol()` in (2) returned an error, then close all of the protocols opened in (2) with `EFI_BOOT_SERVICES.CloseProtocol()`, and return the status code from the call to `OpenProtocol()` that returned an error.
4. Initialize the device specified by `ControllerHandle`. If the driver does not support the device specified by `ControllerHandle`, then close all of the protocols opened in (2) with `CloseProtocol()`, and return `EFI_DEVICE_ERROR`. If the driver does support the device specified by `ControllerHandle` and an error is detected, and that error can not be resolved with the `EFI_DRIVER_HEALTH_PROTOCOL`, then close all of the protocols opened in (2) with `CloseProtocol()`, and return `EFI_DEVICE_ERROR`. If the driver does support the device specified by `ControllerHandle` and an error is detected, and that error can be resolved with the `EFI_DRIVER_HEALTH_PROTOCOL`, then produce the `EFI_DRIVER_HEALTH_PROTOCOL` for `ControllerHandle` and make sure `EFI_SUCCESS` is returned from `Start()`. In this case, depending on the type of error detected, not all of the following steps may be completed.

5. Discover all the child devices of the bus controller specified by *ControllerHandle*.
6. If the bus requires it, allocate resources to all the child devices of the bus controller specified by *ControllerHandle*.
7. FOR each child C of *ControllerHandle*:
 - a. Allocate and initialize all of the data structures that this driver requires to manage the child device C. This would include space for public protocols and space for any additional private data structures that are related to the child device C. If an error occurs allocating the resources, then close all of the protocols opened in (2) with **CloseProtocol()**, and return **EFI_OUT_OF_RESOURCES**.
 - b. If the bus driver creates device paths for the child devices, then create a device path for the child C based upon the device path attached to *ControllerHandle*.
 - c. Initialize the child device C. If an error occurs, close all of the protocols opened in (2) with **CloseProtocol()**, and return **EFI_DEVICE_ERROR**.
 - d. Create a new handle for C, and install the protocol interfaces for child device C using **EFI_BOOT_SERVICES.InstallMultipleProtocolInterfaces()**. This may include the **EFI_DEVICE_PATH_PROTOCOL**.
 - e. Call **OpenProtocol()** on behalf of the child C with an *Attribute* of **EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER**.
8. END FOR
9. If the bus driver also produces protocols on *ControllerHandle*, then install all the new protocol interfaces onto *ControllerHandle* using **InstallMultipleProtocolInterfaces()**. If an error occurs, close all of the protocols opened in (2) with **CloseProtocol()**, and return the error from **InstallMultipleProtocolInterfaces()**.
10. Return **EFI_SUCCESS**.

Bus Driver that is able to create all or one of its child handles on each call to Start():

1. Open all required protocols with **EFI_BOOT_SERVICES.OpenProtocol()**. A standard driver should use an *Attribute* of **EFI_OPEN_PROTOCOL_BY_DRIVER**. If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an *Attribute* of **EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE**. It must use the same *Attribute* value that was used in **Supported()**.
2. If any of the calls to **OpenProtocol()** in (1) returned an error, then close all of the protocols opened in (1) with **EFI_BOOT_SERVICES.CloseProtocol()**, and return the status code from the call to **OpenProtocol()** that returned an error.
3. Initialize the device specified by *ControllerHandle*. If the driver does not support the device specified by *ControllerHandle*, then close all of the protocols opened in (1) with **CloseProtocol()**, and return **EFI_DEVICE_ERROR**. If the driver does support the device specified by *ControllerHandle* and an error is detected, and that error can not be resolved with the **EFI_DRIVER_HEALTH_PROTOCOL**, then close all of the protocols opened in (1) with **CloseProtocol()**, and return **EFI_DEVICE_ERROR**. If the driver does support the device specified by *ControllerHandle* and an error is detected, and that error can be resolved with the **EFI_DRIVER_HEALTH_PROTOCOL**, then produce the **EFI_DRIVER_HEALTH_PROTOCOL** for *ControllerHandle* and make sure

EFI_SUCCESS is returned from **Start()**. In this case, depending on the type of error detected, not all of the following steps may be completed.

4. IF *RemainingDevicePath* is not **NULL**, THEN
 - a C is the child device specified by *RemainingDevicePath*. If the first Device Path Node is the End of Device Path Node, proceed to step 6.
 - b Allocate and initialize all of the data structures that this driver requires to manage the child device C. This would include space for public protocols and space for any additional private data structures that are related to the child device C. If an error occurs allocating the resources, then close all of the protocols opened in (1) with **CloseProtocol()**, and return **EFI_OUT_OF_RESOURCES**.
 - c If the bus driver creates device paths for the child devices, then create a device path for the child C based upon the device path attached to *ControllerHandle*.
 - d Initialize the child device C.
 - e Create a new handle for C, and install the protocol interfaces for child device C using **EFI_BOOT_SERVICES.InstallMultipleProtocolInterfaces()**. This may include the **EFI_DEVICE_PATH_PROTOCOL**.
 - f Call **OpenProtocol()** on behalf of the child C with an *Attribute* of **EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER**.

ELSE

 - a Discover all the child devices of the bus controller specified by *ControllerHandle*.
 - b If the bus requires it, allocate resources to all the child devices of the bus controller specified by *ControllerHandle*.
 - c FOR each child C of *ControllerHandle*

Allocate and initialize all of the data structures that this driver requires to manage the child device C. This would include space for public protocols and space for any additional private data structures that are related to the child device C. If an error occurs allocating the resources, then close all of the protocols opened in (1) with **CloseProtocol()**, and return **EFI_OUT_OF_RESOURCES**.

If the bus driver creates device paths for the child devices, then create a device path for the child C based upon the device path attached to *ControllerHandle*.

Initialize the child device C.

Create a new handle for C, and install the protocol interfaces for child device C using **InstallMultipleProtocolInterfaces()**. This may include the **EFI_DEVICE_PATH_PROTOCOL**.

Call **EFI_BOOT_SERVICES.OpenProtocol()** on behalf of the child C with an *Attribute* of **EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER**.
 - d END FOR
5. END IF
6. If the bus driver also produces protocols on *ControllerHandle*, then install all the new protocol interfaces onto *ControllerHandle* using **InstallMultipleProtocolInterfaces()**. If an error occurs, close all of the protocols opened in (2) with **CloseProtocol()**, and return the error from **InstallMultipleProtocolInterfaces()**.

7. Return **EFI_SUCCESS**.

Listed below is sample code of the [Start\(\)](#) function of a device driver for a device on the XYZ bus. The XYZ bus is abstracted with the **EFI_XYZ_IO_PROTOCOL**. This driver does allow the **EFI_XYZ_IO_PROTOCOL** to be shared with other drivers, and just the presence of the **EFI_XYZ_IO_PROTOCOL** on *ControllerHandle* is enough to determine if this driver supports *ControllerHandle*. This driver installs the **EFI_ABC_IO_PROTOCOL** on *ControllerHandle*. The **gBS** variable is initialized in this driver's entry point as shown in the UEFI Driver Model examples in [Section 1.6](#).

```
extern EFI_GUID          gEfiXyzIoProtocol;
extern EFI_GUID          gEfiAbcIoProtocol;
EFI_BOOT_SERVICES       *gBS;

EFI_STATUS
AbcStart (
    IN EFI_DRIVER_BINDING_PROTOCOL  *This,
    IN EFI_HANDLE                   ControllerHandle,
    IN EFI_DEVICE_PATH_PROTOCOL    *RemainingDevicePath  OPTIONAL
)
{
    EFI_STATUS          Status;
    EFI_XYZ_IO_PROTOCOL *XyzIo;
    EFI_ABC_DEVICE      AbcDevice;

    //
    // Open the Xyz I/O Protocol that this driver consumes
    //
    Status = gBS->OpenProtocol (
        ControllerHandle,
        &gEfiXyzIoProtocol,
        &XyzIo,
        This->DriverBindingHandle,
        ControllerHandle,
        EFI_OPEN_PROTOCOL_BY_DRIVER
    );
    if (EFI_ERROR (Status)) {
        return Status;
    }

    //
    // Allocate and zero a private data structure for the Abc device.
    //
    Status = gBS->AllocatePool (
        EfiBootServicesData,
        sizeof (EFI_ABC_DEVICE),
        &AbcDevice
    );
    if (EFI_ERROR (Status)) {
        goto ErrorExit;
    }
    ZeroMem (AbcDevice, sizeof (EFI_ABC_DEVICE));

    //
    // Initialize the contents of the private data structure for the Abc device.
    // This includes the XyzIo protocol instance and other private data fields
    // and the EFI_ABC_IO_PROTOCOL instance that will be installed.
    //

```

Unified Extensible Firmware Interface Specification

```

        &gEfiXyzIoProtocolGuid,
        This->DriverBindingHandle,
        ControllerHandle
    );
    return Status;
}

```

EFI_DRIVER_BINDING_PROTOCOL.Stop()

Summary

Stops a device controller or a bus controller. The [Start\(\)](#) and [Stop\(\)](#) services of the [EFI_DRIVER_BINDING_PROTOCOL](#) mirror each other.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_BINDING_PROTOCOL_STOP) (
    IN  EFI_DRIVER_BINDING_PROTOCOL  *This,
    IN  EFI_HANDLE                   ControllerHandle,
    IN  UINTN                         NumberOfChildren,
    IN  EFI_HANDLE                   *ChildHandleBuffer  OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_DRIVER_BINDING_PROTOCOL instance. Type EFI_DRIVER_BINDING_PROTOCOL is defined in Section 10.1 .
<i>ControllerHandle</i>	A handle to the device being stopped. The handle must support a bus specific I/O protocol for the driver to use to stop the device.
<i>NumberOfChildren</i>	The number of child device handles in <i>ChildHandleBuffer</i> .
<i>ChildHandleBuffer</i>	An array of child handles to be freed. May be NULL if <i>NumberOfChildren</i> is 0.

Description

This function performs different operations depending on the parameter *NumberOfChildren*. If *NumberOfChildren* is not zero, then the driver specified by *This* is a bus driver, and it is being requested to free one or more of its child handles specified by *NumberOfChildren* and *ChildHandleBuffer*. If all of the child handles are freed, then **EFI_SUCCESS** is returned. If *NumberOfChildren* is zero, then the driver specified by *This* is either a device driver or a bus driver, and it is being requested to stop the controller specified by *ControllerHandle*. If *ControllerHandle* is stopped, then **EFI_SUCCESS** is returned. In either case, this function is required to undo what was performed in [Start\(\)](#). Whatever resources are allocated in [Start\(\)](#) must be freed in [Stop\(\)](#). For example, every [EFI_BOOT_SERVICES.AllocatePool\(\)](#), [EFI_BOOT_SERVICES.AllocatePages\(\)](#), [EFI_BOOT_SERVICES.OpenProtocol\(\)](#), and [EFI_BOOT_SERVICES.InstallProtocolInterface\(\)](#) in [Start\(\)](#) must be matched with a [EFI_BOOT_SERVICES.FreePool\(\)](#), [EFI_BOOT_SERVICES.FreePages\(\)](#), [EFI_BOOT_SERVICES.CloseProtocol\(\)](#), and [EFI_BOOT_SERVICES.UninstallProtocolInterface\(\)](#) in [Stop\(\)](#).

If *ControllerHandle* cannot be stopped, then **EFI_DEVICE_ERROR** is returned. If, for some reason, there are not enough resources to stop *ControllerHandle*, then **EFI_OUT_OF_RESOURCES** is returned.

The **Stop()** function is designed to be invoked from the EFI boot service [EFI_BOOT_SERVICES.DisconnectController\(\)](#). As a result, much of the error checking on the parameters to **Stop()** has been moved into this common boot service. It is legal to call **Stop()** from other locations, but the following calling restrictions must be followed or the system behavior will not be deterministic.

- *ControllerHandle* must be a valid **EFI_HANDLE** that was used on a previous call to this same driver’s [Start\(\)](#) function.
- The first *NumberOfChildren* handles of *ChildHandleBuffer* must all be a valid **EFI_HANDLE**. In addition, all of these handles must have been created in this driver’s **Start()** function, and the **Start()** function must have called [EFI_BOOT_SERVICES.OpenProtocol\(\)](#) on *ControllerHandle* with an *Attribute* of **EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER**.

Status Codes Returned

EFI_SUCCESS	The device was stopped.
EFI_DEVICE_ERROR	The device could not be stopped due to a device error.

Examples

```
extern EFI_GUID          gEfiDriverBindingProtocolGuid;
EFI_HANDLE              DriverImageHandle;
EFI_HANDLE              ControllerHandle;
EFI_HANDLE              ChildHandle;
EFI_DRIVER_BINDING_PROTOCOL *DriverBinding;

//
// Use the DriverImageHandle to get the Driver Binding Protocol instance
//
Status = gBS->OpenProtocol (
    DriverImageHandle,
    &gEfiDriverBindingProtocolGuid,
    &DriverBinding,
    DriverImageHandle,
    NULL,
    EFI_OPEN_PROTOCOL_GET_PROTOCOL
);
if (EFI_ERROR (Status)) {
    return Status;
}

//
// Use the Driver Binding Protocol instance to free the child
// specified by ChildHandle. Then, use the Driver Binding
// Protocol to stop ControllerHandle.
//
Status = DriverBinding->Stop (
    DriverBinding,
    ControllerHandle,
    1,
    &ChildHandle
);

Status = DriverBinding->Stop (
```

```

DriverBinding,
ControllerHandle,
0,
NULL
);

```

Pseudo Code

Device Driver:

1. Uninstall all the protocols that were installed onto *ControllerHandle* in [Start\(\)](#).
2. Close all the protocols that were opened on behalf of *ControllerHandle* in **Start()**.
3. Free all the structures that were allocated on behalf of *ControllerHandle* in **Start()**.
4. Return **EFI_SUCCESS**.

Bus Driver that creates all of its child handles on the first call to Start():

Bus Driver that is able to create all or one of its child handles on each call to Start():

1. IF *NumberOfChildren* is zero THEN:
 - a Uninstall all the protocols that were installed onto *ControllerHandle* in **Start()**.
 - b Close all the protocols that were opened on behalf of *ControllerHandle* in **Start()**.
 - c Free all the structures that were allocated on behalf of *ControllerHandle* in **Start()**.
2. ELSE
 - a FOR each child C in *ChildHandleBuffer*

Uninstall all the protocols that were installed onto C in **Start()**.

Close all the protocols that were opened on behalf of C in **Start()**.

Free all the structures that were allocated on behalf of C in **Start()**.
 - b END FOR
3. END IF
4. Return **EFI_SUCCESS**.

Listed below is sample code of the [Stop\(\)](#) function of a device driver for a device on the XYZ bus. The XYZ bus is abstracted with the **EFI_XYZ_IO_PROTOCOL**. This driver does allow the **EFI_XYZ_IO_PROTOCOL** to be shared with other drivers, and just the presence of the **EFI_XYZ_IO_PROTOCOL** on *ControllerHandle* is enough to determine if this driver supports *ControllerHandle*. This driver installs the **EFI_ABC_IO_PROTOCOL** on *ControllerHandle* in [Start\(\)](#). The **gBS** variable is initialized in this driver's entry point. See [Section 4](#).

```

extern EFI_GUID          gEfiXyzIoProtocol;
extern EFI_GUID          gEfiAbcIoProtocol;
EFI_BOOT_SERVICES       *gBS;

EFI_STATUS
AbcStop (
    IN EFI_DRIVER_BINDING_PROTOCOL *This,
    IN EFI_HANDLE                  ControllerHandle

    ControllerHandle,
    EFI_OPEN_PROTOCOL_GET_PROTOCOL
);
if (EFI_ERROR (Status)) {
    return EFI_UNSUPPORTED;
}

//
// Use Containment Record Macro to get AbcDevice structure from
// a pointer to the AbcIo structure within the AbcDevice structure.
//
AbcDevice = ABC_IO_PRIVATE_DATA_FROM_THIS (AbcIo);

//
// Uninstall the protocol installed in Start()
//
Status = gBS->UninstallMultipleProtocolInterfaces (
    ControllerHandle,
    &gEfiAbcIoProtocolGuid, &AbcDevice->AbcIo,
    NULL
);
if (!EFI_ERROR (Status)) {

    //
    // Close the protocol opened in Start()
    //
    Status = gBS->CloseProtocol (
        ControllerHandle,
        &gEfiXyzIoProtocolGuid,
        This->DriverBindingHandle,
        ControllerHandle
    );

    //
    // Free the structure allocated in Start().
    //
    gBS->FreePool (AbcDevice);
}

return Status;
}
```

10.2 EFI Platform Driver Override Protocol

This section provides a detailed description of the **EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL**. This protocol can override the default algorithm for matching drivers to controllers.

EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL

Summary

This protocol matches one or more drivers to a controller. A platform driver produces this protocol, and it is installed on a separate handle. This protocol is used by the [EFI_BOOT_SERVICES.ConnectController\(\)](#) boot service to select the best driver for a controller. All of the drivers returned by this protocol have a higher precedence than drivers found from an EFI Bus Specific Driver Override Protocol or drivers found from the general UEFI driver Binding search algorithm. If more than one driver is returned by this protocol, then the drivers are returned in order from highest precedence to lowest precedence.

GUID

```
#define EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL_GUID \
{0x6b30c738,0xa391,0x11d4,\
 {0x9a,0x3b,0x00,0x90,0x27,0x3f,0xc1,0x4d}}
```

Protocol Interface Structure

```
typedef struct _EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL {
    EFI_PLATFORM_DRIVER_OVERRIDE_GET_DRIVER      GetDriver;
    EFI_PLATFORM_DRIVER_OVERRIDE_GET_DRIVER_PATH  GetDriverPath;
    EFI_PLATFORM_DRIVER_OVERRIDE_DRIVER_LOADED    DriverLoaded;
} EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL;
```

Parameters

GetDriver	Retrieves the image handle of a platform override driver for a controller in the system. See the GetDriver() function description.
GetDriverPath	Retrieves the device path of a platform override driver for a controller in the system. See the GetDriverPath() function description.
DriverLoaded	This function is used after a driver has been loaded using a device path returned by GetDriverPath() . This function associates a device path to an image handle, so the image handle can be returned the next time that GetDriver() is called for the same controller. See the DriverLoaded() function description.

Description

The **EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL** is used by the EFI boot service [EFI_BOOT_SERVICES.ConnectController\(\)](#) to determine if there is a platform specific

driver override for a controller that is about to be started. The bus drivers in a platform will use a bus defined matching algorithm for matching drivers to controllers. This protocol allows the platform to override the bus driver's default driver matching algorithm. This protocol can be used to specify the drivers for on-board devices whose drivers may be in a system ROM not directly associated with the on-board controller, or it can even be used to manage the matching of drivers and controllers in add-in cards. This can be very useful if there are two adapters that are identical except for the revision of the driver in the adapter's ROM. This protocol, along with a platform configuration utility, could specify which of the two drivers to use for each of the adapters.

The drivers that this protocol returns can be either in the form of an image handle or a device path. [EFI_BOOT_SERVICES.ConnectController\(\)](#) can only use image handles, so [ConnectController\(\)](#) is required to use the [GetDriver\(\)](#) service. A different component, such as the Boot Manager, will have to use the [GetDriverPath\(\)](#) service to retrieve the list of drivers that need to be loaded from I/O devices. Once a driver has been loaded and started, this same component can use the [DriverLoaded\(\)](#) service to associate the device path of a driver with the image handle of the loaded driver. Once this association has been established, the image handle can then be returned by the [GetDriver\(\)](#) service the next time it is called by [ConnectController\(\)](#).

EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriver()

Summary

Retrieves the image handle of the platform override driver for a controller in the system.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PLATFORM_DRIVER_OVERRIDE_GET_DRIVER) (
    IN      EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL  *This,
    IN      EFI_HANDLE                             ControllerHandle,
    IN OUT  EFI_HANDLE                             *DriverImageHandle
);
```

Parameters

<i>This</i>	A pointer to the EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL instance.
<i>ControllerHandle</i>	The device handle of the controller to check if a driver override exists.
<i>DriverImageHandle</i>	On input, a pointer to the previous driver image handle returned by GetDriver() . On output, a pointer to the next driver image handle. Passing in a NULL , will return the first driver image handle for ControllerHandle .

Description

This function is used to retrieve a driver image handle that is selected in a platform specific manner. The first driver image handle is retrieved by passing in a *DriverImageHandle* value of **NULL**. This will cause the first driver image handle to be returned in *DriverImageHandle*. On each successive call, the previous value of *DriverImageHandle* must be passed in. If a call to this function returns a valid driver image handle, then **EFI_SUCCESS** is returned. This process is repeated until **EFI_NOT_FOUND** is returned. If a *DriverImageHandle* is passed in that was not returned on a prior call to this function, then **EFI_INVALID_PARAMETER** is returned. If *ControllerHandle* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. The first driver image handle has the highest precedence, and the last driver image handle has the lowest precedence. This ordered list of driver image handles is used by the boot service [EFI_BOOT_SERVICES.ConnectController\(\)](#) to search for the best driver for a controller.

Status Codes Returned

EFI_SUCCESS	The driver override for <i>ControllerHandle</i> was returned in <i>DriverImageHandle</i> .
EFI_NOT_FOUND	A driver override for <i>ControllerHandle</i> was not found.
EFI_INVALID_PARAMETER	The handle specified by <i>ControllerHandle</i> is not a valid handle.

Unified Extensible Firmware Interface Specification

EFI_INVALID_PARAMETER	<i>DriverImageHandle</i> is not a handle that was returned on a previous call to GetDriver() .
-----------------------	---

EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriverPath()

Summary

Retrieves the device path of the platform override driver for a controller in the system.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PLATFORM_DRIVER_OVERRIDE_GET_DRIVER_PATH) (
    IN      EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL  *This,
    IN      EFI_HANDLE                             ControllerHandle,
    IN OUT  EFI_DEVICE_PATH_PROTOCOL              **DriverImagePath
);
```

Parameters

<i>This</i>	A pointer to the EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL instance.
<i>ControllerHandle</i>	The device handle of the controller to check if a driver override exists.
<i>DriverImagePath</i>	On input, a pointer to the previous driver device path returned by GetDriverPath() . On output, a pointer to the next driver device path. Passing in a pointer to NULL , will return the first driver device path for ControllerHandle .

Description

This function is used to retrieve a driver device path that is selected in a platform specific manner. The first driver device path is retrieved by passing in a *DriverImagePath* value that is a pointer to **NULL**. This will cause the first driver device path to be returned in *DriverImagePath*. On each successive call, the previous value of *DriverImagePath* must be passed in. If a call to this function returns a valid driver device path, then **EFI_SUCCESS** is returned. This process is repeated until **EFI_NOT_FOUND** is returned. If a *DriverImagePath* is passed in that was not returned on a prior call to this function, then **EFI_INVALID_PARAMETER** is returned. If *ControllerHandle* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. The first driver device path has the highest precedence, and the last driver device path has the lowest precedence. This ordered list of driver device paths is used by a platform specific component, such as the EFI Boot Manager, to load and start the platform override drivers by using the EFI boot services [EFI_BOOT_SERVICES.LoadImage\(\)](#) and [EFI_BOOT_SERVICES.StartImage\(\)](#). Each time one of these drivers is loaded and started, the [DriverLoaded\(\)](#) service is called.

Status Codes Returned

EFI_SUCCESS	The driver override for <i>ControllerHandle</i> was returned in <i>DriverImagePath</i> .
EFI_UNSUPPORTED	The operation is not supported.
EFI_NOT_FOUND	A driver override for <i>ControllerHandle</i> was not found.

Unified Extensible Firmware Interface Specification

EFI_INVALID_PARAMETER	The handle specified by <i>ControllerHandle</i> is not a valid handle.
EFI_INVALID_PARAMETER	<i>DriverImagePath</i> is not a device path that was returned on a previous call to GetDriverPath() .

EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.DriverLoaded()

Summary

Used to associate a driver image handle with a device path that was returned on a prior call to the [GetDriverPath\(\)](#) service. This driver image handle will then be available through the [GetDriver\(\)](#) service.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PLATFORM_DRIVER_OVERRIDE_DRIVER_LOADED) (
    IN EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL  *This,
    IN EFI_HANDLE                             ControllerHandle,
    IN EFI_DEVICE_PATH_PROTOCOL               *DriverImagePath,
    IN EFI_HANDLE                             DriverImageHandle
);
```

Parameters

<i>This</i>	A pointer to the EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL instance.
<i>ControllerHandle</i>	The device handle of a controller. This must match the controller handle that was used in a prior call to GetDriver() to retrieve DriverImagePath .
<i>DriverImagePath</i>	A pointer to the driver device path that was returned in a prior call to GetDriverPath() .
<i>DriverImageHandle</i>	The driver image handle that was returned by EFI_BOOT_SERVICES.LoadImage() when the driver specified by DriverImagePath was loaded into memory.

Description

This function associates the image handle specified by [DriverImageHandle](#) with the device path of a driver specified by [DriverImagePath](#). [DriverImagePath](#) must be a value that was returned on a prior call to [GetDriverPath\(\)](#) for the controller specified by [ControllerHandle](#). Once this association has been established, then the service [GetDriver\(\)](#) must return [DriverImageHandle](#) as one of the override drivers for the controller specified by [ControllerHandle](#).

If the association between the image handle specified by [DriverImageHandle](#) and the device path specified by [DriverImagePath](#) is established for the controller specified by [ControllerHandle](#), then [EFI_SUCCESS](#) is returned. If [ControllerHandle](#) is [NULL](#), or [DriverImagePath](#) is not a valid device path, or [DriverImageHandle](#) is [NULL](#), then [EFI_INVALID_PARAMETER](#) is returned. If [DriverImagePath](#) is not a device path that was returned on a prior call to [GetDriverPath\(\)](#) for the controller specified by [ControllerHandle](#), then [EFI_NOT_FOUND](#) is returned.

Status Codes Returned

EFI_SUCCESS	The association between <i>DriverImagePath</i> and <i>DriverImageHandle</i> was established for the controller specified by <i>ControllerHandle</i> .
EFI_UNSUPPORTED	The operation is not supported.
EFI_NOT_FOUND	<i>DriverImagePath</i> is not a device path that was returned on a prior call to GetDriverPath() for the controller specified by <i>ControllerHandle</i> .
EFI_INVALID_PARAMETER	<i>ControllerHandle</i> is not a valid device handle.
EFI_INVALID_PARAMETER	<i>DriverImagePath</i> is not a valid device path.
EFI_INVALID_PARAMETER	<i>DriverImageHandle</i> is not a valid image handle.

10.3 EFI Bus Specific Driver Override Protocol

This section provides a detailed description of the **EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL**. Bus drivers that have a bus specific algorithm for matching drivers to controllers are required to produce this protocol for each controller. For example, a PCI Bus Driver will produce an instance of this protocol for every PCI controller that has a PCI option ROM that contains one or more UEFI drivers. The protocol instance is attached to the handle of the PCI controller.

EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL

Summary

This protocol matches one or more drivers to a controller. This protocol is produced by a bus driver, and it is installed on the child handles of buses that require a bus specific algorithm for matching drivers to controllers. This protocol is used by the [EFI_BOOT_SERVICES.ConnectController\(\)](#) boot service to select the best driver for a controller. All of the drivers returned by this protocol have a higher precedence than drivers found in the general EFI Driver Binding search algorithm, but a lower precedence than those drivers returned by the EFI Platform Driver Override Protocol. If more than one driver image handle is returned by this protocol, then the drivers image handles are returned in order from highest precedence to lowest precedence.

GUID

```
#define EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL_GUID \
{0x3bc1b285,0x8a15,0x4a82,\
 {0xaa,0xbf,0x4d,0x7d,0x13,0xfb,0x32,0x65}}
```

Protocol Interface Structure

```
typedef struct _EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL {
    EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_GET_DRIVER GetDriver;
} EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL;
```

Parameters

GetDriver

Uses a bus specific algorithm to retrieve a driver image handle for a controller. See the [GetDriver\(\)](#) function description.

Description

The `EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL` provides a mechanism for bus drivers to override the default driver selection performed by the `ConnectController()` boot service. This protocol is attached to the handle of a child device after the child handle is created by the bus driver. The service in this protocol can return a bus specific override driver to `ConnectController()`. `ConnectController()` must call this service until all of the bus specific override drivers have been retrieved. `ConnectController()` uses this information along with the EFI Platform Driver Override Protocol and all of the EFI Driver Binding protocol instances to select the best drivers for a controller. Since a controller can be managed by more than one driver, this protocol can return more than one bus specific override driver.

EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL.GetDriver()

Summary

Uses a bus specific algorithm to retrieve a driver image handle for a controller.

Prototype

```

typedef
EFI_STATUS
(EFIAPI *EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_GET_DRIVER) (
    IN      EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL *This,
    IN OUT EFI_HANDLE                                *DriverImageHandle
);

```

Parameters

<i>This</i>	A pointer to the EFI BUS SPECIFIC DRIVER OVERRIDE PROTOCOL instance.
<i>DriverImageHandle</i>	On input, a pointer to the previous driver image handle returned by GetDriver() . On output, a pointer to the next driver image handle. Passing in a NULL , will return the first driver image handle.

Description

This function is used to retrieve a driver image handle that is selected in a bus specific manner. The first driver image handle is retrieved by passing in a *DriverImageHandle* value of **NULL**. This will cause the first driver image handle to be returned in *DriverImageHandle*. On each successive call, the previous value of *DriverImageHandle* must be passed in. If a call to this function returns a valid driver image handle, then **EFI_SUCCESS** is returned. This process is repeated until **EFI_NOT_FOUND** is returned. If a *DriverImageHandle* is passed in that was not returned on a prior call to this function, then **EFI_INVALID_PARAMETER** is returned. The first driver image handle has the highest precedence, and the last driver image handle has the lowest precedence. This ordered list of driver image handles is used by the boot service [EFI_BOOT_SERVICES.ConnectController\(\)](#) to search for the best driver for a controller.

Status Codes Returned

EFI_SUCCESS	A bus specific override driver is returned in <i>DriverImageHandle</i> .
EFI_NOT_FOUND	The end of the list of override drivers was reached. A bus specific override driver is not returned in <i>DriverImageHandle</i> .
EFI_INVALID_PARAMETER	<i>DriverImageHandle</i> is not a handle that was returned on a previous call to GetDriver() .

10.4 EFI Driver Diagnostics Protocol

This section provides a detailed description of the **EFI_DRIVER_DIAGNOSTICS2_PROTOCOL**. This is a protocol that allows a UEFI driver to perform diagnostics on a controller that the driver is managing.

EFI_DRIVER_DIAGNOSTICS2_PROTOCOL

Summary

Used to perform diagnostics on a controller that a UEFI driver is managing.

GUID

```
#define EFI_DRIVER_DIAGNOSTICS2_PROTOCOL_GUID \
{0x4d330321,0x025f,0x4aac, \
  {0x90,0xd8,0x5e,0xd9,0x00,0x17,0x3b,0x63}}
```

Protocol Interface Structure

```
typedef struct _EFI_DRIVER_DIAGNOSTICS2_PROTOCOL {
    EFI_DRIVER_DIAGNOSTICS2_RUN_DIAGNOSTICS  RunDiagnostics;
    CHAR8                                     *SupportedLanguages;
} EFI_DRIVER_DIAGNOSTICS2_PROTOCOL;
```

Parameters

RunDiagnostics Runs diagnostics on a controller. See the [RunDiagnostics\(\)](#) function description.

SupportedLanguages A Null-terminated ASCII string that contains one or more supported language codes. This is the list of language codes that this protocol supports. The number of languages supported by a driver is up to the driver writer. *SupportedLanguages* is specified in RFC 4646 format. See [Appendix M](#) for the format of language codes and language code arrays.

Description

The **EFI_DRIVER_DIAGNOSTICS2_PROTOCOL** is used by a platform management utility to allow the user to run driver specific diagnostics on a controller. This protocol is optionally attached to the image handle of driver in the driver's entry point. The platform management utility can collect

all the **EFI_DRIVER_DIAGNOSTICS2_PROTOCOL** instances present in the system, and present the user with a menu of the controllers that have diagnostic capabilities. This platform management utility is invoked through a platform component such as the EFI Boot Manager.

EFI_DRIVER_DIAGNOSTICS2_PROTOCOL.RunDiagnostics()

Summary

Runs diagnostics on a controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_DIAGNOSTICS2_RUN_DIAGNOSTICS) (
    IN  EFI_DRIVER_DIAGNOSTICS2_PROTOCOL *This,
    IN  EFI_HANDLE                       ControllerHandle,
    IN  EFI_HANDLE                       ChildHandle OPTIONAL,
    IN  EFI_DRIVER_DIAGNOSTIC_TYPE       DiagnosticType,
    IN  CHAR8                             *Language,
    OUT EFI_GUID                          **ErrorType,
    OUT UINTN                             *BufferSize,
    OUT CHAR16                            **Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_DRIVER_DIAGNOSTICS2_PROTOCOL instance.
<i>ControllerHandle</i>	The handle of the controller to run diagnostics on.
<i>ChildHandle</i>	The handle of the child controller to run diagnostics on. This is an optional parameter that may be NULL . It will be NULL for device drivers. It will also be NULL for a bus drivers that attempt to run diagnostics on the bus controller. It will not be NULL for a bus driver that attempts to run diagnostics on one of its child controllers.
<i>DiagnosticType</i>	Indicates type of diagnostics to perform on the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> . See “Related Definitions” for the list of supported types.
<i>Language</i>	A pointer to a Null-terminated ASCII string array indicating the language. This is the language in which the optional error message should be returned in <i>Buffer</i> , and it must match one of the languages specified in <i>SupportedLanguages</i> . The number of languages supported by a driver is up to the driver writer. <i>Language</i> is specified in RFC 4646 language code format. See Appendix M for the format of language codes. Callers of interfaces that require RFC 4646 language codes to retrieve a Unicode string must use the RFC 4647 algorithm to lookup the Unicode string with the closest matching RFC 4646 language code.
<i>ErrorType</i>	A GUID that defines the format of the data returned in <i>Buffer</i> .
<i>BufferSize</i>	The size, in bytes, of the data returned in <i>Buffer</i> .

Buffer

A buffer that contains a Null-terminated string plus some additional data whose format is defined by *ErrorType*. *Buffer* is allocated by this function with [EFI_BOOT_SERVICES.AllocatePool\(\)](#), and it is the caller's responsibility to free it with a call to [EFI_BOOT_SERVICES.FreePool\(\)](#).

Description

This function runs diagnostics on the controller specified by *ControllerHandle* and *ChildHandle*. *DiagnosticType* specifies the type of diagnostics to perform on the controller specified by *ControllerHandle* and *ChildHandle*. If the driver specified by *This* does not support the language specified by *Language*, then **EFI_UNSUPPORTED** is returned. If the controller specified by *ControllerHandle* and *ChildHandle* is not supported by the driver specified by *This*, then **EFI_UNSUPPORTED** is returned. If the diagnostics type specified by *DiagnosticType* is not supported by this driver, then **EFI_UNSUPPORTED** is returned. If there are not enough resources available to complete the diagnostic, then **EFI_OUT_OF_RESOURCES** is returned. If the controller specified by *ControllerHandle* and *ChildHandle* passes the diagnostic, then **EFI_SUCCESS** is returned. Otherwise, **EFI_DEVICE_ERROR** is returned.

If the language specified by *Language* is supported by this driver, then status information is returned in *ErrorType*, *BufferSize*, and *Buffer*. *Buffer* contains a Null-terminated string followed by additional data whose format is defined by *ErrorType*. *BufferSize* is the size of *Buffer* in bytes, and it is the caller's responsibility to call **FreePool()** on *Buffer* when the caller is done with the return data. If there are not enough resources available to return the status information, then **EFI_OUT_OF_RESOURCES** is returned.

Related Definitions

```

//*****
// EFI_DRIVER_DIAGNOSTIC_TYPE
//*****
typedef enum {
    EfiDriverDiagnosticTypeStandard           = 0,
    EfiDriverDiagnosticTypeExtended          = 1,
    EfiDriverDiagnosticTypeManufacturing     = 2,
    EfiDriverDiagnosticTypeCancel           = 3,
    EfiDriverDiagnosticTypeMaximum
} EFI_DRIVER_DIAGNOSTIC_TYPE;

```

EfiDriverDiagnosticTypeStandard

Performs standard diagnostics on the controller. This diagnostic type is required to be supported by all implementations of this protocol.

EfiDriverDiagnosticTypeExtended

This is an optional diagnostic type that performs diagnostics on the controller that may take an extended amount of time to execute.

EfiDriverDiagnosticTypeManufacturing

This is an optional diagnostic type that performs diagnostics on the controller that are suitable for a manufacturing and test environment.

EfiDriverDiagnosticTypeCancel

This is an optional diagnostic type that would only be used in the situation where an `EFI_NOT_READY` had been returned by a previous call to `RunDiagnostics()` and there is a desire to cancel the current running diagnostics operation.

Status Codes Returned

EFI_SUCCESS	The controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> passed the diagnostic.
EFI_ACCESS_DENIED	The request for initiating diagnostics was unable to be completed due to some underlying hardware or software state.
EFI_INVALID_PARAMETER	<i>ControllerHandle</i> is NULL .
EFI_INVALID_PARAMETER	The driver specified by <i>This</i> is not a device driver, and <i>ChildHandle</i> is not NULL .
EFI_INVALID_PARAMETER	<i>Language</i> is NULL .
EFI_INVALID_PARAMETER	<i>ErrorType</i> is NULL .
EFI_INVALID_PARAMETER	<i>BufferSize</i> is NULL .
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL .
EFI_UNSUPPORTED	The driver specified by <i>This</i> does not support running diagnostics for the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> .
EFI_UNSUPPORTED	The driver specified by <i>This</i> does not support the type of diagnostic specified by <i>DiagnosticType</i> .
EFI_UNSUPPORTED	The driver specified by <i>This</i> does not support the language specified by <i>Language</i> .
EFI_OUT_OF_RESOURCES	There are not enough resources available to complete the diagnostics.
EFI_OUT_OF_RESOURCES	There are not enough resources available to return the status information in <i>ErrorType</i> , <i>BufferSize</i> , and <i>Buffer</i> .
EFI_DEVICE_ERROR	The controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> did not pass the diagnostic.
EFI_NOT_READY	The diagnostic operation was started, but not yet completed.

10.5 EFI Component Name Protocol

This section provides a detailed description of the `EFI_COMPONENT_NAME2_PROTOCOL`. This is a protocol that allows an driver to provide a user readable name of a UEFI Driver, and a user readable name for each of the controllers that the driver is managing. This protocol is used by

platform management utilities that wish to display names of components. These names may include the names of expansion slots, external connectors, embedded devices, and add-in devices.

EFI_COMPONENT_NAME2_PROTOCOL

Summary

Used to retrieve user readable names of drivers and controllers managed by UEFI Drivers.

GUID

```
#define EFI_COMPONENT_NAME2_PROTOCOL_GUID \
{0x6a7a5cff, 0xe8d9, 0x4f70, \
 0xba, 0xda, 0x75, 0xab, 0x30, 0x25, 0xce, 0x14}
```

Protocol Interface Structure

```
typedef struct _EFI_COMPONENT_NAME2_PROTOCOL {
  EFI_COMPONENT_NAME_GET_DRIVER_NAME      GetDriverName;
  EFI_COMPONENT_NAME_GET_CONTROLLER_NAME  GetControllerName;
  CHAR8                                    *SupportedLanguages;
} EFI_COMPONENT_NAME2_PROTOCOL;
```

Parameters

<i>GetDriverName</i>	Retrieves a string that is the user readable name of the driver. See the GetDriverName() function description.
<i>GetControllerName</i>	Retrieves a string that is the user readable name of a controller that is being managed by a driver. See the GetControllerName() function description.
<i>SupportedLanguages</i>	A Null-terminated ASCII string array that contains one or more supported language codes. This is the list of language codes that this protocol supports. The number of languages supported by a driver is up to the driver writer. <i>SupportedLanguages</i> is specified in RFC 4646 format. See Appendix M for the format of language codes and language code arrays.

Description

The **EFI_COMPONENT_NAME2_PROTOCOL** is used to retrieve a driver's user readable name and the names of all the controllers that a driver is managing from the driver's point of view. Each of these names is returned as a Null-terminated string. The caller is required to specify the language in which the string is returned, and this language must be present in the list of languages that this protocol supports specified by *SupportedLanguages*.

EFI_COMPONENT_NAME2_PROTOCOL.GetDriverName()

Summary

Retrieves a string that is the user readable name of the driver.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_COMPONENT_NAME_GET_DRIVER_NAME) (
    IN  EFI_COMPONENT_NAME2_PROTOCOL *This,
    IN  CHAR8                        *Language,
    OUT CHAR16                       **DriverName
);
```

Parameters

<i>This</i>	A pointer to the EFI_COMPONENT_NAME2_PROTOCOL instance.
<i>Language</i>	A pointer to a Null-terminated ASCII string array indicating the language. This is the language of the driver name that the caller is requesting, and it must match one of the languages specified in SupportedLanguages. The number of languages supported by a driver is up to the driver writer. <i>Language</i> is specified in RFC 4646 language code format. See Appendix M for the format of language codes. Callers of interfaces that require RFC 4646 language codes to retrieve a Unicode string must use the RFC 4647 algorithm to lookup the Unicode string with the closest matching RFC 4646 language code.
<i>DriverName</i>	A pointer to the string to return. This string is the name of the driver specified by <i>This</i> in the language specified by <i>Language</i> .

Description

This function retrieves the user readable name of a driver in the form of a string. If the driver specified by *This* has a user readable name in the language specified by *Language*, then a pointer to the driver name is returned in *DriverName*, and **EFI_SUCCESS** is returned. If the driver specified by *This* does not support the language specified by *Language*, then **EFI_UNSUPPORTED** is returned.

Status Codes Returned

EFI_SUCCESS	The string for the user readable name in the language specified by <i>Language</i> for the driver specified by <i>This</i> was returned in <i>DriverName</i> .
EFI_INVALID_PARAMETER	<i>Language</i> is NULL .

Unified Extensible Firmware Interface Specification

EFI_INVALID_PARAMETER	<i>DriverName</i> is NULL .
EFI_UNSUPPORTED	The driver specified by <i>This</i> does not support the language specified by <i>Language</i> .

EFI_COMPONENT_NAME2_PROTOCOL.GetControllerName()

Summary

Retrieves a string that is the user readable name of the controller that is being managed by a driver.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_COMPONENT_NAME_GET_CONTROLLER_NAME) (
    IN  EFI_COMPONENT_NAME2_PROTOCOL  *This,
    IN  EFI_HANDLE                    ControllerHandle,
    IN  EFI_HANDLE                    ChildHandle      OPTIONAL,
    IN  CHAR8                         *Language,
    OUT CHAR16                        **ControllerName
);
```

Parameters

<i>This</i>	A pointer to the EFI COMPONENT NAME2 PROTOCOL instance.
<i>ControllerHandle</i>	The handle of a controller that the driver specified by <i>This</i> is managing. This handle specifies the controller whose name is to be returned.
<i>ChildHandle</i>	The handle of the child controller to retrieve the name of. This is an optional parameter that may be NULL . It will be NULL for device drivers. It will also be NULL for bus drivers that attempt to retrieve the name of the bus controller. It will not be NULL for a bus driver that attempts to retrieve the name of a child controller.
<i>Language</i>	A pointer to a Null- terminated ASCII string array indicating the language. This is the language of the controller name that the caller is requesting, and it must match one of the languages specified in SupportedLanguages. The number of languages supported by a driver is up to the driver writer. <i>Language</i> is specified in RFC 4646 language code format. See Appendix M for the format of language codes. Callers of interfaces that require RFC 4646 language codes to retrieve a Unicode string must use the RFC 4647 algorithm to lookup the Unicode string with the closest matching RFC 4646 language code.
<i>ControllerName</i>	A pointer to the string to return. This string is the name of the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> in the language specified by <i>Language</i> from the point of view of the driver specified by <i>This</i> .

Description

This function retrieves the user readable name of the controller specified by *ControllerHandle* and *ChildHandle* in the form of a string. If the driver specified by *This* has a user readable name in the language specified by *Language*, then a pointer to the controller name is returned in *ControllerName*, and **EFI_SUCCESS** is returned.

If the driver specified by *This* is not currently managing the controller specified by *ControllerHandle* and *ChildHandle*, then **EFI_UNSUPPORTED** is returned.

If the driver specified by *This* does not support the language specified by *Language*, then **EFI_UNSUPPORTED** is returned.

Status Codes Returned

EFI_SUCCESS	The string for the user readable name specified by <i>This</i> , <i>ControllerHandle</i> , <i>ChildHandle</i> , and <i>Language</i> was returned in <i>ControllerName</i> .
EFI_INVALID_PARAMETER	<i>ControllerHandle</i> is NULL .
EFI_INVALID_PARAMETER	The driver specified by <i>This</i> is not a device driver, and <i>ChildHandle</i> is not NULL .
EFI_INVALID_PARAMETER	<i>Language</i> is NULL .
EFI_INVALID_PARAMETER	<i>ControllerName</i> is NULL .
EFI_UNSUPPORTED	The driver specified by <i>This</i> is a device driver and <i>ChildHandle</i> is not NULL .
EFI_UNSUPPORTED	The driver specified by <i>This</i> is not currently managing the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> .
EFI_UNSUPPORTED	The driver specified by <i>This</i> does not support the language specified by <i>Language</i> .

10.6 EFI Service Binding Protocol

This section provides a detailed description of the **EFI_SERVICE_BINDING_PROTOCOL**. This protocol may be produced only by drivers that follow the UEFI Driver Model. Use this protocol with the **EFI_DRIVER_BINDING_PROTOCOL** to produce a set of protocols related to a device. The **EFI_DRIVER_BINDING_PROTOCOL** supports simple layering of protocols on a device, but it does not support more complex relationships such as trees or graphs. The **EFI_SERVICE_BINDING_PROTOCOL** provides a member function to create a child handle with a new protocol installed on it, and another member function to destroy a previously created child handle. These member functions apply equally to all drivers.

EFI_SERVICE_BINDING_PROTOCOL

Summary

Provides services that are required to create and destroy child handles that support a given set of protocols.

GUID

This protocol does not have its own GUID. Instead, drivers for other protocols will define a GUID that shares the same protocol interface as the **EFI_SERVICE_BINDING_PROTOCOL**. The protocols defined in this document that have this property include the following:

- **EFI_MANAGED_NETWORK_SERVICE_BINDING_PROTOCOL**
- **EFI_ARP_SERVICE_BINDING_PROTOCOL**
- **EFI_EAP_SERVICE_BINDING_PROTOCOL**
- **EFI_IP4_SERVICE_BINDING_PROTOCOL**
- **EFI_TCP4_SERVICE_BINDING_PROTOCOL**
- **EFI_UDP4_SERVICE_BINDING_PROTOCOL**
- **EFI_MTFTP4_SERVICE_BINDING_PROTOCOL**
- **EFI_DHCP4_SERVICE_BINDING_PROTOCOL**

Protocol Interface Structure

```
typedef struct _EFI_SERVICE_BINDING_PROTOCOL {
    EFI_SERVICE_BINDING_CREATE_CHILD    CreateChild;
    EFI_SERVICE_BINDING_DESTROY_CHILD  DestroyChild;
} EFI_SERVICE_BINDING_PROTOCOL;
```

Parameters

<i>CreateChild</i>	Creates a child handle and installs a protocol. See the CreateChild() function description.
<i>DestroyChild</i>	Destroys a child handle with a protocol installed on it. See the DestroyChild() function description.

Description

The **EFI_SERVICE_BINDING_PROTOCOL** provides member functions to create and destroy child handles. A driver is responsible for adding protocols to the child handle in **CreateChild()** and removing protocols in **DestroyChild()**. It is also required that the **CreateChild()** function opens the parent protocol BY_CHILD_CONTROLLER to establish the parent-child relationship, and closes the protocol in **DestroyChild()**. The pseudo code for **CreateChild()** and **DestroyChild()** is provided to specify the required behavior, not to specify the required implementation. Each consumer of a software protocol is responsible for calling **CreateChild()** when it requires the protocol and calling **DestroyChild()** when it is finished with that protocol.

EFI_SERVICE_BINDING_PROTOCOL.CreateChild()

Summary

Creates a child handle and installs a protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERVICE_BINDING_CREATE_CHILD) (
    IN EFI_SERVICE_BINDING_PROTOCOL      *This,
    IN OUT EFI_HANDLE                    *ChildHandle
);
```

Parameters

<i>This</i>	Pointer to the EFI_SERVICE_BINDING_PROTOCOL instance.
<i>ChildHandle</i>	Pointer to the handle of the child to create. If it is a pointer to NULL , then a new handle is created. If it is a pointer to an existing UEFI handle, then the protocol is added to the existing UEFI handle.

Description

The **CreateChild()** function installs a protocol on *ChildHandle*. If *ChildHandle* is a pointer to **NULL**, then a new handle is created and returned in *ChildHandle*. If *ChildHandle* is not a pointer to **NULL**, then the protocol installs on the existing *ChildHandle*.

Status Codes Returned

EFI_SUCCESS	The protocol was added to <i>ChildHandle</i> .
EFI_INVALID_PARAMETER	<i>ChildHandle</i> is NULL .
EFI_OUT_OF_RESOURCES	There are not enough resources available to create the child.
Other	The child handle was not created.

Examples

The following example shows how a consumer of the EFI ARP Protocol would use the **CreateChild()** function of the **EFI_SERVICE_BINDING_PROTOCOL** to create a child handle with the EFI ARP Protocol installed on that handle.

```

EFI_HANDLE          ControllerHandle;
EFI_HANDLE          DriverBindingHandle;
EFI_HANDLE          ChildHandle;
EFI_ARP_SERVICE_BINDING_PROTOCOL *ArpSb;
EFI_ARP_PROTOCOL    *Arp;

//
// Get the ArpServiceBinding Protocol
//
Status = gBS->OpenProtocol (
    ControllerHandle,
    &gEfiArpServiceBindingProtocolGuid,
    (VOID **) &ArpSb,
    DriverBindingHandle,
    ControllerHandle,
    EFI_OPEN_PROTOCOL_GET_PROTOCOL
);
if (EFI_ERROR (Status)) {
    return Status;
}
//
// Initialize a ChildHandle
//
ChildHandle = NULL;
//
// Create a ChildHandle with the Arp Protocol
//
Status = ArpSb->CreateChild (ArpSb, &ChildHandle);
if (EFI_ERROR (Status)) {
    goto ErrorExit;
}

//
// Retrieve the Arp Protocol from ChildHandle
//
Status = gBS->OpenProtocol (
    ChildHandle,
    &gEfiArpProtocolGuid,
    (VOID **) &Arp,
    DriverBindingHandle,
    ControllerHandle,
    EFI_OPEN_PROTOCOL_BY_DRIVER
);
if (EFI_ERROR (Status)) {
    goto ErrorExit;
}

```

Pseudo Code

The following is the general algorithm for implementing the `CreateChild()` function:

1. Allocate and initialize any data structures that are required to produce the requested protocol on a child handle. If the allocation fails, then return `EFI_OUT_OF_RESOURCES`.
2. Install the requested protocol onto `ChildHandle`. If `ChildHandle` is a pointer to `NULL`, then the requested protocol installs onto a new handle.
3. Open the parent protocol `BY_CHILD_CONTROLLER` to establish the parent-child relationship. If the parent protocol cannot be opened, then destroy the `ChildHandle` created in step 2, free the data structures allocated in step 1, and return an error.
4. Increment the number of children created by `CreateChild()`.
5. Return `EFI_SUCCESS`.

Listed below is sample code of the `CreateChild()` function of the EFI ARP Protocol driver.

This driver looks up its private context data structure from the instance of the

`EFI_SERVICE_BINDING_PROTOCOL` produced on the handle for the network controller. After retrieving the private context data structure, the driver can use its contents to build the private context data structure for the child being created. The EFI ARP Protocol driver then installs the `EFI_ARP_PROTOCOL` onto `ChildHandle`.

```

EFI_STATUS
EFIAPI
ArpServiceBindingCreateChild (
    IN EFI_SERVICE_BINDING_PROTOCOL *This,
    IN EFI_HANDLE                    *ChildHandle
)
{
    EFI_STATUS      Status;
    ARP_PRIVATE_DATA *Private;
    ARP_PRIVATE_DATA *PrivateChild;

    //
    // Retrieve the Private Context Data Structure
    //
    Private = ARP_PRIVATE_DATA_FROM_SERVICE_BINDING_THIS (This);

    //
    // Create a new child
    //
    PrivateChild = EfiLibAllocatePool (sizeof (ARP_PRIVATE_DATA));
    if (PrivateChild == NULL) {
        return EFI_OUT_OF_RESOURCES;
    }
}

```

```

//
// Copy Private Context Data Structure
//
gBS->CopyMem (PrivateChild, Private, sizeof (ARP_PRIVATE_DATA));

//
// Install Arp onto ChildHandle
//
Status = gBS->InstallMultipleProtocolInterfaces (
    ChildHandle,
    &gEfiArpProtocolGuid, &PrivateChild->Arp,
    NULL
);
if (EFI_ERROR (Status)) {
    gBS->FreePool (PrivateChild);
    return Status;
}

Status = gBS->OpenProtocol (
    Private->ChildHandle,
    &gEfiManagedNetworkProtocolGuid,
    (VOID **)&PrivateChild->ManagedNetwork,
    gArpDriverBinding.DriverBindingHandle,
    *ChildHandle,
    EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER
);
if (EFI_ERROR (Status)) {
    ArpSB->DestroyChild (This, ChildHandle);
    return Status;
}

//
// Increase number of children created
//
Private->NumberCreated++;

return EFI_SUCCESS;
}

```

EFI_SERVICE_BINDING_PROTOCOL.DestroyChild()

Summary

Destroys a child handle with a protocol installed on it.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERVICE_BINDING_DESTROY_CHILD) (
    IN EFI_SERVICE_BINDING_PROTOCOL *This,
    IN EFI_HANDLE ChildHandle
);
```

Parameters

This Pointer to the **EFI_SERVICE_BINDING_PROTOCOL** instance.

ChildHandle Handle of the child to destroy.

Description

The **DestroyChild()** function does the opposite of **CreateChild()**. It removes a protocol that was installed by **CreateChild()** from *ChildHandle*. If the removed protocol is the last protocol on *ChildHandle*, then *ChildHandle* is destroyed.

Status Codes Returned

EFI_SUCCESS	The protocol was removed from <i>ChildHandle</i> .
EFI_UNSUPPORTED	<i>ChildHandle</i> does not support the protocol that is being removed.
EFI_INVALID_PARAMETER	<i>ChildHandle</i> is not a valid UEFI handle.
EFI_ACCESS_DENIED	The protocol could not be removed from the <i>ChildHandle</i> because its services are being used.
Other	The child handle was not destroyed.

Examples

The following example shows how a consumer of the EFI ARP Protocol would use the **DestroyChild()** function of the **EFI_SERVICE_BINDING_PROTOCOL** to destroy a child handle with the EFI ARP Protocol installed on that handle.

```

EFI_HANDLE                ControllerHandle;
EFI_HANDLE                DriverBindingHandle;
EFI_HANDLE                ChildHandle;
EFI_ARP_SERVICE_BINDING_PROTOCOL *Arp;

//
// Get the Arp Service Binding Protocol
//
Status = gBS->OpenProtocol (
    ControllerHandle,
    &gEfiArpServiceBindingProtocolGuid,
    (VOID **) &ArpSb,
    DriverBindingHandle,
    ControllerHandle,
    EFI_OPEN_PROTOCOL_GET_PROTOCOL
);
if (EFI_ERROR (Status)) {
    return Status;
}

//
// Destroy the ChildHandle with the Arp Protocol
//
Status = ArpSb->DestroyChild (ArpSb, ChildHandle);
if (EFI_ERROR (Status)) {
    return Status;
}

```

Pseudo Code

The following is the general algorithm for implementing the **DestroyChild()** function:

1. Retrieve the protocol from *ChildHandle*. If this retrieval fails, then return **EFI_SUCCESS** because the child has already been destroyed.
2. If this call is a recursive call to destroy the same child, then return **EFI_SUCCESS**.
3. Close the parent protocol with **CloseProtocol()**.
4. Set a flag to detect a recursive call to destroy the same child.
5. Remove the protocol from *ChildHandle*. If this removal fails, then reopen the parent protocol and clear the flag to detect a recursive call to destroy the same child.
6. Free any data structures that allocated in **CreateChild()**.
7. Decrement the number of children that created with **CreateChild()**.
8. Return **EFI_SUCCESS**.

Listed below is sample code of the **DestroyChild()** function of the EFI ARP Protocol driver. This driver looks up its private context data structure from the instance of the **EFI_SERVICE_BINDING_PROTOCOL** produced on the handle for the network controller. The driver attempts to retrieve the **EFI_ARP_PROTOCOL** from *ChildHandle*. If that fails, then **EFI_SUCCESS** is returned. The **EFI_ARP_PROTOCOL** is then used to retrieve the private context

data structure for the child. The private context data stores the flag that detects if **DestroyChild()** is being called recursively. If a recursion is detected, then **EFI_SUCCESS** is returned. Otherwise, the **EFI_ARP_PROTOCOL** is removed from *ChildHandle*, the number of children are decremented, and **EFI_SUCCESS** is returned.

```

EFI_STATUS
EFIAPI
ArpServiceBindingDestroyChild (
    IN EFI_SERVICE_BINDING_PROTOCOL *This,
    IN EFI_HANDLE                    ChildHandle
)
{
    EFI_STATUS          Status;
    EFI_ARP_PROTOCOL   *Arp;
    ARP_PRIVATE_DATA   *Private;
    ARP_PRIVATE_DATA   *PrivateChild;

    //
    // Retrieve the Private Context Data Structure
    //
    Private = ARP_PRIVATE_DATA_FROM_SERVICE_BINDING_THIS (This);

    //
    // Retrieve Arp Protocol from ChildHandle
    //
    Status = gBS->OpenProtocol (
        ChildHandle,
        &EfiArpProtocolGuid,
        (VOID **) &Arp,
        gArpDriverBinding.DriverBindingHandle,
        ChildHandle,
        EFI_OPEN_PROTOCOL_GET_PROTOCOL
    );
    if (EFI_ERROR (Status)) {
        return EFI_SUCCESS;
    }

    //
    // Retrieve Private Context Data Structure
    //
    PrivateChild = ARP_PRIVATE_DATA_FROM_ARP_THIS (Arp);
    if (PrivateChild->Destroy) {
        return EFI_SUCCESS;
    }

    //
    // Close the ManagedNetwork Protocol
    //
    gBS->CloseProtocol (
        Private->ChildHandle,
        &EfiManagedNetworkProtocolGuid,
        gArpDriverBinding.DriverBindingHandle,

```

```

        ChildHandle
    );

    PrivateChild->Destroy = TRUE;

    //
    // Uninstall Arp from ChildHandle
    //
    Status = gBS->UninstallMultipleProtocolInterfaces (
        ChildHandle,
        &gEfiArpProtocolGuid, &PrivateChild->Arp,
        NULL
    );
    if (EFI_ERROR (Status)) {
        //
        // Uninstall failed, so reopen the parent Arp Protocol and
        // return an error
        //
        PrivateChild->Destroy = FALSE;
        gBS->OpenProtocol (
            Private->ChildHandle,
            &gEfiManagedNetworkProtocolGuid,
            (VOID **)&PrivateChild->ManagedNetwork,
            gArpDriverBinding.DriverBindingHandle,
            ChildHandle,
            EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER
        );
        return Status;
    }

    //
    // Free Private Context Data Structure
    //
    gBS->FreePool (PrivateChild);

    //
    // Decrease number of children created
    //
    Private->NumberCreated--;

    return EFI_SUCCESS;

```

10.7 EFI Platform to Driver Configuration Protocol

This section provides a detailed description of the **EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL**. This is a protocol that is

optionally produced by the platform and optionally consumed by a UEFI Driver in its **Start()** function. This protocol allows the driver to receive configuration information as part of being started.

EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL

Summary

Used to retrieve configuration information for a device that a UEFI driver is about to start.

GUID

```
#define EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL_GUID \
  { 0x642cd590, 0x8059, 0x4c0a, \
    { 0xa9, 0x58, 0xc5, 0xec, 0x07, 0xd2, 0x3c, 0x4b } }
```

Protocol Interface Structure

```
typedef struct _EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL {
  EFI_PLATFORM_TO_DRIVER_CONFIGURATION_QUERY      Query;
  EFI_PLATFORM_TO_DRIVER_CONFIGURATION_RESPONSE   Response;
} EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL;
```

Parameters

<i>Query</i>	Called by the UEFI Driver Start() function to get configuration information from the platform.
<i>Response</i>	Called by the UEFI Driver Start() function to let the platform know how UEFI driver processed the data return from <i>Query</i> .

Description

The **EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL** is used by the UEFI driver to query the platform for configuration information. The UEFI driver calls [Query\(\)](#) multiple times to get configuration information from the platform. For every call to *Query()* there must be a matching call to [Response\(\)](#) so the UEFI driver can inform the platform how it used the information passed in from *Query()*.

It's legal for a UEFI driver to use *Response()* to inform the platform it does not understand the data returned via *Query()* and thus no action was taken.

EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL.Query()

Summary

Allows the UEFI driver to query the platform for configuration information needed to complete the drivers `Start()` operation.

Prototype

```

typedef
EFI_STATUS
(EFIAPI *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_QUERY) (
    IN  EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL  *This,
    IN  EFI_HANDLE                                     ControllerHandle,
    IN  EFI_HANDLE                                     ChildHandle  OPTIONAL,
    IN  UINTN                                          *Instance,
    OUT EFI_GUID                                       **ParameterTypeGuid,
    OUT VOID                                           **ParameterBlock,
    OUT UINTN                                          *ParameterBlockSize
);

```

Parameters

<i>This</i>	A pointer to the EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL instance.
<i>ControllerHandle</i>	The handle the platform will return configuration information about.
<i>ChildHandle</i>	The handle of the child controller to return information on. This is an optional parameter that may be NULL . It will be NULL for device drivers, and for bus drivers that attempt to get options for the bus controller. It will not be NULL for a bus driver that attempts to get options for one of its child controllers.
<i>Instance</i>	Pointer to the Instance value. Zero means return the first query data. The caller should increment this value by one each time to retrieve successive data.
<i>ParameterTypeGuid</i>	An EFI_GUID that defines the contents of <i>ParameterBlock</i> . UEFI drivers must use the <i>ParameterTypeGuid</i> to determine how to parse the <i>ParameterBlock</i> . The caller should not attempt to free <i>ParameterTypeGuid</i> .
<i>ParameterBlock</i>	The platform returns a pointer to the <i>ParameterBlock</i> structure which contains details about the configuration parameters specific to the <i>ParameterTypeGuid</i> . This structure is defined based on the protocol and may be different for different protocols. UEFI driver decodes this structure and its contents based on <i>ParameterTypeGuid</i> . <i>ParameterBlock</i> is allocated by the platform and the

platform is responsible for freeing the *ParameterBlock* after **Response** is called.

ParameterBlockSize The platform returns the size of the *ParameterBlock* in bytes.

Description

The UEFI driver must call *Query* early in the **Start()** function before any time consuming operations are performed. If *ChildHandle* is **NULL** the driver is requesting information from the platform about the *ControllerHandle* that is being started. Information returned from *Query* may lead to the drivers **Start()** function failing.

If the UEFI driver is a bus driver and producing a *ChildHandle* the driver must call *Query* after the child handle has been created and an **EFI_DEVICE_PATH_PROTOCOL** has been placed on that handle, but before any time consuming operation is performed. If information return by *Query* may lead the driver to decide to not create the *ChildHandle*. The driver must then cleanup and remove the *ChildHandle* from the system.

The UEFI driver repeatedly calls *Query*, processes the information returned by the platform, and calls *Response* passing in the arguments returned from *Query*. The *Instance* value passed into *Response* must be the same value passed to the corresponding call to *Query*. The UEFI driver must continuously call *Query* and *Response* until **EFI_NOT_FOUND** is returned by *Query*.

If the UEFI driver does not recognize the *ParameterTypeGuid*, it calls *Response* with a *ConfigurationAction* of **EfiPlatformConfigurationActionUnsupportedGuid**. The UEFI driver must then continue calling *Query* and *Response* until **EFI_NOT_FOUND** is returned by *Query*. This gives the platform an opportunity to pass additional configuration settings using a different *ParameterTypeGuid* that may be supported by the driver.

An *Instance* value of zero means return the first *ParameterBlock* in the set of unprocessed parameter blocks. The driver should increment the *Instance* value by one for each successive call to *Query*.

Status Codes Returned

EFI_SUCCESS	The platform return parameter information for <i>ControllerHandle</i> .
EFI_NOT_FOUND	No more unread <i>Instance</i> exists.
EFI_INVALID_PARAMETER	<i>ControllerHandle</i> is NULL .
EFI_INVALID_PARAMETER	<i>Instance</i> is NULL .
EFI_DEVICE_ERROR	A device error occurred while attempting to return parameter block information for the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> .
EFI_OUT_RESOURCES	There are not enough resources available to set the configuration options for the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> .

EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL.Response()

Summary

Tell the platform what actions were taken by the driver after processing the data returned from *Query*.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_RESPONSE) (
    IN  EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL  *This,
    IN  EFI_HANDLE                                     ControllerHandle,
    IN  EFI_HANDLE                                     ChildHandle OPTIONAL,
    IN  UINTN                                          *Instance,
    IN  EFI_GUID                                       *ParameterTypeGuid,
    IN  VOID                                           *ParameterBlock,
    IN  UINTN                                          ParameterBlockSize ,
    IN  EFI_PLATFORM_CONFIGURATION_ACTION              ConfigurationAction
);
```

Parameters

<i>This</i>	A pointer to the EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL instance.
<i>ControllerHandle</i>	The handle the driver is returning configuration information about.
<i>ChildHandle</i>	The handle of the child controller to return information on. This is an optional parameter that may be NULL . It will be NULL for device drivers, and for bus drivers that attempt to get options for the bus controller. It will not be NULL for a bus driver that attempts to get options for one of its child controllers.
<i>Instance</i>	Instance data passed to Query() .
<i>ParameterTypeGuid</i>	<i>ParameterTypeGuid</i> returned from <i>Query</i> .
<i>ParameterBlock</i>	<i>ParameterBlock</i> returned from <i>Query</i> .
<i>ParameterBlockSize</i>	The <i>ParameterBlock</i> size returned from <i>Query</i> .
<i>ConfigurationAction</i>	The driver tells the platform what action is required for <i>ParameterBlock</i> to take effect. See "Related Definitions" for a list of actions.

Description

The UEFI driver repeatedly calls *Query*, processes the information returned by the platform, and calls *Response* passing in the arguments returned from *Query*. The UEFI driver must continuously call *Query* until **EFI_NOT_FOUND** is returned. For every call to *Query* that returns **EFI_SUCCESS** a corresponding call to *Response* is required passing in the same

ControllerHandle, *ChildHandle*, *Instance*, *ParameterTypeGuid*, *ParameterBlock*, and *ParameterBlockSize*. The UEFI driver may update values in *ParameterBlock* based on rules defined by *ParameterTypeGuid*.

The platform is responsible for freeing *ParameterBlock* and the UEFI driver must not try to free it.

Related Definitions

```
typedef enum {
    EfiPlatformConfigurationActionNone           = 0,
    EfiPlatformConfigurationActionStopController = 1,
    EfiPlatformConfigurationActionRestartController = 2,
    EfiPlatformConfigurationActionRestartPlatform = 3,
    EfiPlatformConfigurationActionNvramFailed    = 4,
    EfiPlatformConfigurationActionUnsupportedGuid = 5,
    EfiPlatformConfigurationActionMaximum
} EFI_PLATFORM_CONFIGURATION_ACTION;
```

EfiPlatformConfigurationActionNone

The controller specified by *ControllerHandle* is still in a usable state, it's configuration has been updated via parsing the *ParameterBlock*. If required by the parameter block and the module supports an NVRAM store the configuration information from *ParameterBlock* was successfully saved to the NVRAM. No actions are required before this controller can be used again with the updated configuration settings

EfiPlatformConfigurationStopController

The driver has detected that the controller specified by *ControllerHandle* is not in a usable state, and it needs to be stopped. The calling agent can use the [EFI_BOOT_SERVICES.DisconnectController\(\)](#) service to perform this operation, and it should be performed as soon as possible.

EfiPlatformConfigurationRestartController

This controller specified by *ControllerHandle* needs to be stopped and restarted before it can be used again. The calling agent can use the [DisconnectController\(\)](#) and [EFI_BOOT_SERVICES.ConnectController\(\)](#) services to perform this operation. The restart operation can be delayed until all of the configuration options have been set.

EfiPlatformConfigurationRestartPlatform

A configuration change has been made that requires the platform to be restarted before the controller specified by *ControllerHandle* can be used again. The calling agent can use the [ResetSystem\(\)](#) services to perform this operation. The restart operation can be delayed until all of the configuration options have been set.

EfiPlatformConfigurationActionNvramFailed

The controller specified by *ControllerHandle* is still in a usable state; its configuration has been updated via parsing the *ParameterBlock*. The driver tried to update the driver's private NVRAM store with information from *ParameterBlock* and failed. No actions are required before this controller can be used again with the updated configuration settings, but these configuration settings are not guaranteed to persist after *ControllerHandle* is stopped.

EfiPlatformConfigurationActionUnsupportedGuid

The controller specified by *ControllerHandle* is still in a usable state; its configuration has not been updated via parsing the *ParameterBlock*. The driver did not support the *ParameterBlock* format identified by *ParameterTypeGuid*. No actions are required before this controller can be used again. On additional *Query* calls from this *ControllerHandle*, the platform should stop returning a *ParameterBlock* qualified by this same *ParameterTypeGuid*. If no other *ParameterTypeGuid* is supported by the platform, *Query* should return **EFI_NOT_FOUND**.

Status Codes Returned

EFI_SUCCESS	The platform return parameter information for <i>ControllerHandle</i> .
EFI_NOT_FOUND	<i>Instance</i> was not found.
EFI_INVALID_PARAMETER	<i>ControllerHandle</i> is NULL .

10.7.1 DMTF SM CLP ParameterTypeGuid

The following parameter protocol *ParameterTypeGuid* provides the support for parameters communicated through the DMTF SM CLP Specification 1.0 Final Standard to be used to configure the UEFI driver.

In this section the producer of the

EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL is platform firmware and the consumer is the UEFI driver.

Note: If future versions of the DMTF SM CLP Specification require changes to the parameter block definition, newer *ParameterTypeGuid* will be used.

GUID

```
#define EFI_PLATFORM_TO_DRIVER_CONFIGURATION_CLP_GUID \
    {0x345ecc0e, 0xcb6, 0x4b75, \
     {0xbb, 0x57, 0x1b, 0x12, 0x9c, 0x47, 0x33, 0x3e}}
```

Parameter Block

```
typedef struct {
    CHAR8      *CLPCommand;
    UINT32     CLPCommandLength;
    CHAR8      *CLPReturnString;
    UINT32     CLPReturnStringLength;
    UINT8      CLPCmdStatus;
    UINT8      CLPErrorValue;
    UINT16     CLPMsgCode;
} EFI_CONFIGURE_CLP_PARAMETER_BLK;
```

Structure Member Definitions

<i>CLPCommand</i>	A pointer to the null-terminated UTF-8 string that specifies the DMTF SM CLP command line that the driver is required to parse and process when this function is called. See the <i>DMTF SM CLP Specification 1.0</i> Final Standard for details on the format and syntax of the CLP command line string. <i>CLPCommand</i> buffer is allocated by the producer of the EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL .
<i>CLPCommandLength</i>	The length of the CLP Command in bytes.
<i>CLPReturnString</i>	A pointer to the null-terminated UTF-8 string that indicates the CLP return status that the driver is required to provide to the calling agent. The calling agent may parse and/or pass this for processing and user feedback. The SM CLP Command Response string buffer is filled in by the UEFI driver in the “keyword=value” format described in the <i>SM CLP Specification</i> (see section 3.table 101, “Output Data”), unless otherwise requested via the SM CLP –output option in the Command Line string buffer. UEFI driver’s support for this default “keyword=value” output format is required if the UEFI driver supports this protocol, while support for other SM CLP output formats is optional. (The UEFI Driver should set CLPCmdStatus=2 (COMMAND PROCESSING FAILED) and CLPErrorValue=249 (OUTPUT FORMAT NOT SUPPORTED) if the SM CLP –output option requested by the caller is not supported by the UEFI Driver.).

CLPReturnString buffer is allocated by the consumer of the **EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL** and undefined prior to the call to *Response()*.

<i>CLPReturnStringLength</i>	The length of the CLP return status string in bytes.
<i>CLPCmdStatus</i>	SM CLP Command Status (see <i>DMTF SM CLP Specification 1.0 Final Standard</i> - Table 4)
<i>CLPErrorValue</i>	SM CLP Processing Error Value (see <i>DMTF SM CLP Specification 1.0 Final Standard</i> - Table 6). This field is filled in by the consumer of the EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL and undefined prior to the call to Response() .
<i>CLPMsgCode</i>	Bit 15: OEM Message Code Flag 0 = Message Code is an SM CLP Probable Cause Value. (see SM CLP Specification Table 11) 1 = Message Code is OEM Specific Bits 14-0: Message Code This field is filled in by the consumer of the EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL and undefined prior to the call to Response() .

10.8 EFI Driver Supported EFI Version Protocol

EFI_DRIVER_SUPPORTED_EFI_VERSION_PROTOCOL

Summary

Provides information about the version of the EFI specification that a driver is following. This protocol is required for EFI drivers that are on PCI and other plug in cards.

GUID

```
#define EFI_DRIVER_SUPPORTED_EFI_VERSION_PROTOCOL_GUID \
    { 0x5c198761, 0x16a8, 0x4e69, \
      { 0x97, 0x2c, 0x89, 0xd6, 0x79, 0x54, 0xf8, 0x1d } }
```

Protocol Interface Structure

```
typedef struct _EFI_DRIVER_SUPPORTED_EFI_VERSION_PROTOCOL {
    UINT32      Length;
    UINT32      FirmwareVersion;
} EFI_DRIVER_SUPPORTED_EFI_VERSION_PROTOCOL;
```

Parameters

Length The size, in bytes, of the entire structure. Future versions of this specification may grow the size of the structure.

FirmwareVersion The latest version of the UEFI Specification that this driver conforms to. Refer to the **EFI_SPECIFICATION_VERSION** definition in [Section 4.3](#).

Description

The **EFI_DRIVER_SUPPORTED_EFI_VERSION_PROTOCOL** provides a mechanism for an EFI driver to publish the version of the EFI specification it conforms to. This protocol must be placed on the driver's image handle when the driver's entry point is called.

10.9 EFI Driver Family Override Protocol

10.9.1 Overview

This section defines the Driver Family Override Protocol, and contains the following:

- Description and code definitions of the Driver Family Override Protocol.
- Required updates to the EFI Boot Services `ConnectController()`.
- Typical production of the Driver Family Override Protocol by an EFI Driver that follows the EFI Driver Model.

The Driver Family Override Protocol provides a method for an EFI Driver to opt-in to a higher priority rule for connecting drivers to controllers in the EFI Boot Service **ConnectController()**. This new rule is higher priority than the Bus Specific Driver Override Protocol rule and lower priority than the Platform Driver Override Rule.

The Driver Family Override Protocol is a backwards compatible extension to the EFI Driver Model and is only available during boot time. The Driver Family Override Protocol may be optionally produced by a driver that follows the EFI Driver Model. If this protocol is produced, it must be installed onto the Driver Image Handle. Drivers that follow the EFI Driver Model typically install the EFI Driver Binding Protocol onto the driver's image handle. In this case, the Driver Family Override Protocol must also be installed onto the driver's image handle. If a single EFI Driver produces more than one instance of the EFI Driver Binding Protocol, then the Driver Family Override Protocol must be installed onto the same handle as the EFI Driver Binding Protocol that is associated with the Driver Family Override Protocol. Since it is legal for a single EFI Driver to produce multiple EFI Driver Binding Protocol instances, it is also legal for a single EFI Driver to produce multiple Driver Family Override Protocol instances.

EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL

Summary

When installed, the Driver Family Override Protocol informs the UEFI Boot Service **ConnectController()** that this driver is higher priority than the list of drivers returned by the Bus Specific Driver Override Protocol.

GUID

```
#define EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL_GUID \
    {0xblee129e,0xda36,0x4181,\
     0x91,0xf8,0x04,0xa4,0x92,0x37,0x66,0xa7}
```

Protocol Interface Structure

```
typedef struct _EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL {
    EFI_DRIVER_FAMILY_OVERRIDE_GET_VERSION  GetVersion;
} EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL;
```

Parameters

GetVersion

Retrieves the version of the driver that is used by the EFI Boot Service **ConnectController()** to sort the set of Driver Binding Protocols in order from highest priority to lowest priority. For drivers that support the Driver Family Override Protocol, those drivers are sorted so that the drivers with higher values returned by **GetVersion()** are high priority that drivers that return lower values from **GetVersion()**.

Description

This protocol contains a single service that returns a version value for the driver that produces this protocol. High values are higher priority than lower values when evaluated by the EFI Boot Service **ConnectController()**. This is an optional protocol that may be produced by an EFI Driver that follows the EFI Driver Model. If this protocol is produced, it must be installed onto a handle that also contains the EFI Driver Binding Protocol.

If this protocol is not produced by an EFI Driver, then the rules used to connect a driver to a controller from highest priority to lowest priority are as follows:

- Context Override
- Platform Driver Override
- Bus Specific Driver Override Protocol
- Driver Binding Search

If this protocol is produced by an EFI Driver, then the rules used to connect a driver to a controller from highest priority to lowest priority are as follows:

- Context Override
- Platform Driver Override
- Driver Family Override
- Bus Specific Driver Override
- Driver Binding Search

EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL.GetVersion ()

Summary

Retrieves the version of the driver that is used by the EFI Boot Service `ConnectController()` to sort the set of Driver Binding Protocols in order from highest priority to lowest priority. For drivers that support the Driver Family Override Protocol, those drivers are sorted so that the drivers with higher values returned by `GetVersion()` are high priority that drivers that return lower values from `GetVersion()`.

Prototype

```
typedef
UINT32
(EFI_API *EFI_DRIVER_FAMILY_OVERRIDE_GET_VERSION) (
    IN EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL *This
);
```

Parameters

This

A pointer to the `EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL` instance.

Description

This function returns the version value associated with the driver specified by *This*.

10.10 EFI Driver Health Protocol

This section contains the basic definitions of the Driver Health Protocol.

EFI_DRIVER_HEALTH_PROTOCOL

Summary

When installed, the Driver Health Protocol produces a collection of services that allow the health status for a controller to be retrieved. If a controller is not in a usable state, status messages may be reported to the user, repair operations can be invoked, and the user may be asked to make software and/or hardware configuration changes. All display, as well as interaction, with the user must be handled by the consumer of the Driver Health Protocol.

GUID

```
#define EFI_DRIVER_HEALTH_PROTOCOL_GUID \
    {0x2a534210, 0x9280, 0x41d8, \
     {0xae, 0x79, 0xca, 0xda, 0x01, 0xa2, 0xb1, 0x27 } }
```

Protocol Interface Structure

```
typedef struct _EFI_DRIVER_HEALTH_PROTOCOL {
    EFI_DRIVER_HEALTH_GET_HEALTH_STATUS    GetHealthStatus;
    EFI_DRIVER_HEALTH_REPAIR               Repair;
} EFI_DRIVER_HEALTH_PROTOCOL;
```

Parameters

<i>GetHealthStatus</i>	Retrieves the health status of a controller in the platform. This function can also optionally return warning messages, error messages, and an HII Form that may be used to repair a controller that is not properly configured.
<i>Repair</i>	Performs a repair operation on a controller in the platform. This function can optionally report repair progress information back to the platform.

Description

The Driver Health Protocol is optionally produced by a driver that follows the EFI Driver Model. If an EFI Driver needs to report health status to the platform, provide warning or error messages to the user, perform length repair operations, or request the user to make hardware or software configuration changes, then the Driver Health Protocol must be produced.

A controller that is managed by driver that follows the EFI Driver Model and produces the Driver Health Protocol must report the current health of the controllers that the driver is currently managing. The controller can initially be healthy, failed, require repair, or require configuration. If a controller requires configuration, and the user make configuration changes, the controller may then need to be reconnected or the system may need to be rebooted for the configuration changes to take effect. Figure 2-1 below shows all the possible health states of a controller, the set of initial states, the set of terminal states, and the legal transitions between the health states.

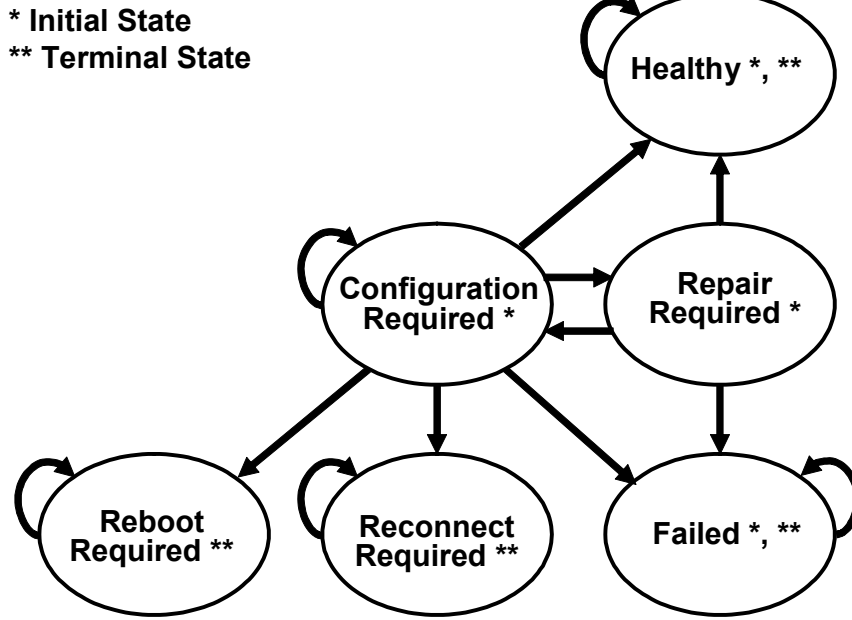

Figure 28. Driver Health Status States

EFI_DRIVER_HEALTH_PROTOCOL.GetHealthStatus()

Summary

Retrieves the health status of a controller in the platform. This function can also optionally return warning messages, error messages, and an HII Form that may be used to repair a controller that is not proper configured.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_HEALTH_GET_HEALTH_STATUS) (
    IN  EFI_DRIVER_HEALTH_PROTOCOL  *This,
    IN  EFI_HANDLE                  ControllerHandle,  OPTIONAL
    IN  EFI_HANDLE                  ChildHandle,        OPTIONAL
    OUT EFI_DRIVER_HEALTH_STATUS    *HealthStatus,
    OUT EFI_DRIVER_HEALTH_HII_MESSAGE **MessageList,    OPTIONAL
    OUT EFI_HII_HANDLE              *FormHiiHandle      OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_DRIVER_HEALTH_PROTOCOL instance.
<i>ControllerHandle</i>	The handle of the controller to retrieve the health status on. This is an optional parameter that may be NULL . If this parameter is NULL , then the value of <i>ChildHandle</i> is ignored, and the combined health status of all the devices that the driver is managing is returned.
<i>ChildHandle</i>	The handle of the child controller to retrieve the health status on. This is an optional parameter that may be NULL . It will be NULL for device drivers. It will also be NULL for bus drivers when an attempt is made to collect the health status of the bus controller. If will not be NULL when an attempt is made to collect the health status for a child controller produced by the driver. If <i>ControllerHandle</i> is NULL , then this parameter is ignored.
<i>HealthStatus</i>	A pointer to the health status that is returned by this function. The health status for the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> is returned.
<i>MessageList</i>	A pointer to an array of warning or error messages associated with the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> . This is an optional parameter that may be NULL . <i>MessageList</i> is allocated by this function with the EFI Boot Service AllocatePool() , and it is the caller's responsibility to free <i>MessageList</i> with the EFI Boot Service FreePool() . Each message is specified by tuple of an EFI_HII_HANDLE and an EFI_STRING_ID . The array of messages is terminated by tuple containing a EFI_HII_HANDLE with a value of NULL . The EFI_HII_STRING_PROTOCOL.GetString() function can

be used to retrieve the warning or error message as a Null-terminated string in a specific language. Messages may be returned for any of the *HealthStatus* values except **EfiDriverHealthStatusReconnectRequired** and **EfiDriverHealthStatusRebootRequired**.

FormHiiHandle

A pointer to the HII handle containing the HII form used when configuration is required. The HII handle is associated with the controller specified by *ControllerHandle* and *ChildHandle*. If this is **NULL**, then no HII form is available. An HII handle will only be returned with a *HealthStatus* value of **EfiDriverHealthStatusConfigurationRequired**.

Description

This function returns the health status associated with the controller specified by *ControllerHandle* and *ChildHandle*. If *ControllerHandle* is not **NULL** and the driver specified by *This* is not currently managing the controller specified by *ControllerHandle* and *ChildHandle*, then **EFI_UNSUPPORTED** is returned. If *HealthStatus* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *ControllerHandle* is **NULL**, then the cumulative health status of all the controllers managed by the EFI driver is returned. If all the controller manages by the driver are healthy, then **EfiDriverHealthStatusHealthy** must be returned in *HealthStatus*. If one or more of the controllers managed by the EFI Driver is not healthy, then **EfiDriverHealthStatusFailed** must be returned.

If *ControllerHandle* is not **NULL** and *ChildHandle* is **NULL**, then the health status of the controller specified by *ControllerHandle* is returned in *HealthStatus* and **EFI_SUCCESS** is returned.

If *ControllerHandle* is not **NULL** and *ChildHandle* is not **NULL**, then the health status of the child controller specified by *ControllerHandle* and *ChildHandle* is returned in *HealthStatus* and **EFI_SUCCESS** is returned.

If *MessageList* is **NULL**, then no messages are returned from this function.

If *MessageList* is not **NULL**, and *HealthStatus* is **EfiDriverHealthStatusReconnectRequired** or **EfiDriverHealthStatusRebootRequired** then no messages are returned and **MessageList* must be set to **NULL**.

If *MessageList* is not **NULL**, and there are no warning or error messages associated with the controller specified by *ControllerHandle* and *ChildHandle*, then **MessageList* must be set to **NULL**.

If *MessageList* is not **NULL**, and there are one or more warning or error messages associated with the controller specified by *ControllerHandle* and *ChildHandle*, then **MessageList* must point to a buffer allocated with the EFI Boot Service **AllocatePool()**. The number of **EFI_DRIVER_HEALTH_HII_MESSAGE** structures allocated in the buffer must be one more than the total number of warning or error messages, and the *HiiHandle* field of the last **EFI_DRIVER_HEALTH_HII_MESSAGE** structure must be set to **NULL** to terminate the list of messages. It is the caller's responsibility to free the buffer returned in **MessageList* using

the EFI Boot Service **FreePool()**. Each message is specified by an **EFI_HII_HANDLE** and an **EFI_STRING_ID**. The caller may use the **EFI_HII_STRING_PROTOCOL.GetString()** function to convert each message into a Null-terminated string that can may be displayed on a console device.

If *FormHiiHandle* is **NULL**, then no forms are returned from this function.

If *FormHiiHandle* is not **NULL**, and *HealthStatus* is not **EfiDriverHealthStatusConfigurationRequired**, then no forms are returned and **FormHiiHandle* must be set to **NULL**.

If *FormHiiHandle* is not **NULL**, and *FormSetGuid* is not **NULL**, and *HealthStatus* is **EfiDriverHealthStatusConfigurationRequired**, then *FormHiiHandle* is assigned to the HII handle which contains the HII form required to perform the configuration operation.

Related Definitions

```

//*****
// EFI_DRIVER_HEALTH_STATUS
//*****
typedef enum {
    EfiDriverHealthStatusHealthy,
    EfiDriverHealthStatusRepairRequired,
    EfiDriverHealthStatusConfigurationRequired,
    EfiDriverHealthStatusFailed,
    EfiDriverHealthStatusReconnectRequired,
    EfiDriverHealthStatusRebootRequired
} EFI_DRIVER_HEALTH_STATUS;
    
```

EfiDriverHealthStatusHealthy

The controller is in a healthy state.

EfiDriverHealthStatusRepairRequired

The controller requires a repair operation that will take an extended period of time to perform. The EFI Boot Manager is required to call the **Repair()** function when this state is detected. After the **Repair()** function completed, the health status may be **EfiDriverHealthStatusHealthy**, **EfiDriverHealthStatusConfigurationRequired**, or **EfiDriverHealthStatusFailed**.

EfiDriverHealthStatusConfigurationRequired

The controller requires the user to make software or hardware configuration changes in order to put the controller into a healthy state. The set of software configuration changes are specified by the *FormHiiHandle* and *FormSetGuid* parameters. The EFI Boot Manager may call the **EFI_FORM_BROWSER2_PROTOCOL.SendForm()** function to display configuration information and allow the user to make the required configuration changes. The HII form is the first enabled form in the form set class **EFI_HII_DRIVER_HEALTH_FORMSET_GUID**, which is installed on the returned HII handle *FormHiiHandle*. The *MessageList* parameter may be used to

identify additional user configuration operations required to place the controller in a healthy state. After the *FormHiiHandle* and *MessageList* have been processed by the EFI Boot Manager, the health status may be

EfiDriverHealthStatusHealthy,
EfiDriverHealthStatusConfigurationRequired,
EfiDriverHealthStatusRepairRequired,
EfiDriverHealthStatusFailed,
EfiDriverHealthStatusReconnectRequired, or
EfiDriverHealthStatusRebootRequired.

EfiDriverHealthStatusFailed

The controller is in a failed state, and there no actions that can place the controller into a healthy state. This controller can not be used as a boot device and no boot devices behind this controller can be used as a boot device.

EfiDriverHealthStatusReconnectRequired

A hardware and/or software configuration change was performed by the user, and the controller needs to be reconnected before the controller can be placed in a healthy state. The EFI Boot Manager is required to call the EFI Boot Service **DisconnectController()** followed by the EFI Boot Service **ConnectController()** to reconnect the controller.

EfiDriverHealthStatusRebootRequired

A hardware and/or software configuration change was performed by the user, and the controller requires the entire platform to be rebooted before the controller can be placed in a healthy state. The EFI Boot Manager should complete the configuration and repair operations on all the controllers that are not in a healthy state before rebooting the system.

```

//*****
// EFI_DRIVER_HEALTH_HII_MESSAGE
//*****
typedef struct {
    EFI_HII_HANDLE  HiiHandle;
    EFI_STRING_ID   StringId;
    UINT64          MessageCode;
} EFI_DRIVER_HEALTH_HII_MESSAGE;

```

HiiHandle The **EFI_HII_HANDLE** that was returned by **EFI_HII_DATABASE_PROTOCOL.NewPackageList()** when the string pack containing *StringId* was registered with the HII Database.

StringId The identifier for a single string token in the string pack associated with *HiiHandle*.

MessageCode 64-bit numeric value of the warning/error specified by this message. A value of **0x0000000000000000** is used to indicate that *MessageCode* is not specified.

The values **0x0000000000000001** to **0x0fffffffffffffffffff** are reserved for allocation by the UEFI Specification.

The values **0x1000000000000000** to **0x1fffffffffffffffffff** are reserved for IHV-developed drivers.

The values **0x8000000000000000** to **0x8fffffffffffffffffff** is reserved for platform/OEM drivers.

All other values are reserved and should not be used.

Status Codes Returned

EFI_SUCCESS	The health status of the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> was returned in <i>HealthStatus</i> . A list of warning and error messages may be optionally returned in <i>MessageList</i> , and an HII Form may be optionally specified by <i>FormHiiHandle</i> .
EFI_UNSUPPORTED	<i>ControllerHandle</i> is not NULL , and the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> is not currently being managed by the driver specified by <i>This</i> .
EFI_INVALID_PARAMETER	<i>HealthStatus</i> is NULL .
EFI_OUT_OF_RESOURCES	<i>MessageList</i> is not NULL , and there are not enough resource available to allocate memory for <i>MessageList</i> .

EFI_DRIVER_HEALTH_PROTOCOL.Repair ()

Summary

Performs a repair operation on a controller in the platform. This function can optionally report repair progress information back to the platform.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_HEALTH_REPAIR) (
    IN EFI_DRIVER_HEALTH_PROTOCOL      *This,
    IN EFI_HANDLE                      ControllerHandle,
    IN EFI_HANDLE                      ChildHandle      OPTIONAL,
    IN EFI_DRIVER_HEALTH_REPAIR_NOTIFY RepairNotify     OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_DRIVER_HEALTH_PROTOCOL instance.
<i>ControllerHandle</i>	The handle of the controller to repair.
<i>ChildHandle</i>	The handle of the child controller to repair. This is an optional parameter that may be NULL . It will be NULL for device drivers. It will also be NULL for bus drivers when an attempt is made to repair a bus controller. It will not be NULL when an attempt is made to repair a child controller produced by the driver.
<i>RepairNotify</i>	A notification function that may be used by a driver to report the progress of the repair operation. This is an optional parameter that may be NULL .

Description

This function repairs the controller specified by *ControllerHandle* and *ChildHandle*. If the driver specified by *This* is not currently managing the controller specified by *ControllerHandle* and *ChildHandle*, then **EFI_UNSUPPORTED** is returned. If there are not enough resources available to complete the repair operation, then **EFI_OUT_OF_RESOURCES** is returned. Otherwise, **EFI_SUCCESS** is returned. A return value of **EFI_SUCCESS** does not guarantee that the controller is in a healthy state. The EFI Boot Manager must call the **GetHealthStatus ()** function to determine the result of the repair operation.

If *RepairNotify* is not **NULL**, and the repair operation requires an extended period of time to execute, then the driver performing the repair operation may intermittently call the *RepairNotify* function to inform the EFI Boot Manager of the progress of the repair operation. The *RepairNotify* function takes two parameters to specify the current progress value and the limit value. These two values may be used by the EFI Boot Manager to present status information for the current repair operation.

Related Definitions

```

//*****
// EFI_DRIVER_HEALTH_REPAIR_NOTIFY
//*****
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_HEALTH_REPAIR_NOTIFY) (
    IN UINTN    Value,
    IN UINTN    Limit
);
    
```

Value A value between 0 and Limit that identifies the current progress of the repair operation.

Limit The maximum value of Value for the current repair operation. If Limit is 0, then the completion progress is indeterminate. For example, a driver that wants to specify progress in percent would use a Limit value of 100.

Status Codes Returned

EFI_SUCCESS	An attempt to repair the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> was performed. The result of the repair operation can bet determined by calling GetHealthStatus() .
EFI_UNSUPPORTED	The driver specified by This is not currently managing the controller specified by <i>ControllerHandle</i> and <i>ChildHandle</i> .
EFI_OUT_OF_RESOURCES	There are not enough resources to perform the repair operation.

10.10.1 UEFI Boot Manager Algorithms

This section contains example algorithms that a UEI Boot Manager or UEFI Application could use to interact with one or more instances of the EFI Driver Health Protocol present in the platform.

10.10.1.1 All Controllers Healthy

This section contains example algorithms that a UEI Boot Manager or UEFI Application could use to interact with one or more instances of the EFI Driver Health Protocol present in the platform.

The following algorithm collects all the EFI Driver Health Protocols currently present in the EFI Handle Database, and queries each EFI Driver Health Protocol to determine if one or more of the controllers managed by each EFI Driver Health Protocol instance are not healthy. The variable **AllHealthy** is **TRUE** if all the controllers in the platform are healthy. **AllHealthy** is **FALSE** if one of more of the controllers in the platform are not healthy.

```

EFI_STATUS                Status;
UINTN                    NoHandles;
EFI_HANDLE                *Handles;
UINTN                    Index;
EFI_DRIVER_HEALTH_PROTOCOL *DriverHealth;
BOOLEAN                  AllHealthy;

Status = gBS->LocateHandleBuffer (
    ByProtocol,
    &gEfiDriverHealthProtocolGuid,
    NULL,
    &NoHandles,
    &Handles
);
if (EFI_ERROR (Status)) {
    return;
}

AllHealthy = TRUE;
for (Index = 0; Index < NoHandles; Index++) {
    Status = gBS->HandleProtocol (
        Handles[Index],
        &gEfiDriverHealthProtocolGuid,
        (VOID **) &DriverHealth
    );
    if (!EFI_ERROR (Status)) {
        Status = DriverHealth->GetHealthStatus (
            DriverHealth,
            NULL,
            NULL,
            NULL,
            NULL,
            NULL
        );
        if (EFI_ERROR (Status)) {
            AllHealthy = FALSE;
        }
    }
}
}

```

10.10.1.2 Process a Controller Until Terminal State Reached

The following algorithm processes a single controller using the EFI Driver Health Protocol associated with that controller. This algorithm continues to query the **GetHealthStatus ()** service until one of the legal terminal states of the EFI Driver Health Protocol is reached. This may require the processing of HII Messages, HII Form, and invocation of repair operations.

Unified Extensible Firmware Interface Specification

```
EFI_STATUS                               Status;
EFI_DRIVER_HEALTH_PROTOCOL               *DriverHealth;
EFI_HANDLE                               ControllerHandle;
EFI_HANDLE                               ChildHandle;
EFI_DRIVER_HEALTH_HEALTH_STATUS         HealthStatus;
EFI_DRIVER_HEALTH_HII_MESSAGE           *MessageList;
EFI_HII_HANDLE                           FormHiiHandle;

do {
    HealthStatus = EfiDriverHealthStatusHealthy;
    Status = DriverHealth->GetHealthStatus (
        DriverHealth,
        ControllerHandle,
        ChildHandle,
        &HealthStatus,
        &MessageList,
        &FormHiiHandle
    );
    ProcessMessages (MessageList);
    if (HealthStatus == EfiDriverHealthStatusRepairRequired) {
        Status = DriverHealth->Repair (
            DriverHealth,
            ControllerHandle,
            ChildHandle,
            RepairNotify
        );
    }
    if (HealthStatus == EfiDriverHealthStatusConfigurationRequired) {
        ProcessForm (FormHiiHandle);
    }
} while (HealthStatus == EfiDriverHealthStatusConfigurationRequired ||
        HealthStatus == EfiDriverHealthStatusRepairRequired);
//
// Check for RebootRequired or ReconnectRequired
//
```

10.10.1.3 Repair Notification Function

The following is an example repair notification function.

```
VOID
RepairNotify (
    UINTN Value,
    UINTN Limit
)
{
    UINTN Percent;

    if (Limit == 0) {
        Print (L"Repair Progress Undefined\n\r");
    } else {
        Percent = Value * 100 / Limit;
        Print (L"Repair Progress = %3d%%", Percent);
    }
}
```

10.10.1.4 Process Message List

The following algorithm processes a set of messages returned by the **GetHealthStatus()** service of the EFI Driver Health Protocol.

Unified Extensible Firmware Interface Specification

```
EFI_STATUS                               Status;
EFI_DRIVER_HEALTH_HII_MESSAGE           *MessageList;
UINTN                                    MessageIndex;
EFI_HII_STRING_PROTOCOL                 *HiiString;
EFI_STRING                               MessageString[200];

for (MessageIndex = 0;
     MessageList[MessageIndex].HiiHandle != 0;
     MessageIndex++) {
    MessageLength = sizeof (MessageString);
    Status = HiiString->GetString (
        HiiString,
        NULL,
        MessageList[MessageIndex].HiiHandle,
        MessageList[MessageIndex].StringId,
        MessageString
        &MessageLength,
        NULL
    );
    if (!EFI_ERROR (Status)) {
        // Log or Print or Display MessageString
    }
}
```

10.10.1.5 Process HII Form

The following algorithm processes an HII Form returned by the **GetHealthStatus ()** service of the EFI Driver Health Protocol.

```

EFI_STATUS                               Status;
EFI_FORM_BROWSER2_PROTOCOL               *FormBrowser;
EFI_HII_HANDLE                           FormHiiHandle;

```

```

Status = FormBrowser->SendForm (
    FormBrowser,
    &FormHiiHandle,
    1,
    &gEfiHiiDriverHealthFormsetGuid,
    ,
    0,
    NULL,
    NULL
);

```

10.10.2 UEFI Driver Algorithms

A UEFI Driver that supports the EFI Driver Health Protocol will typically make the following changes:

10.10.2.1 Driver Entry Point Updates

Install Driver Health Protocol on the driver image handle.

Register HII String/IFR packs with the HII Database

- HII String/IFR packs can also be carried in a PE/COFF image extension eliminating the need for the driver to perform the registration
- The HII String and HII Forms may be produced dynamically when the GetHealthStatus() service is called.

10.10.2.2 •Add global variable

Add global variable to track combined health status of all controllers managed by the driver. The variable is TRUE if all the controllers managed by the driver are healthy. The variable is FALSE if one or more controllers managed by the drover are not healthy.

10.10.2.3 Update private context structure

Update private context structure to track health status of each controller managed by the driver. This may also include the current set of HII Strings and HII Forms associated with the controllers that are not healthy.

10.10.2.4 Implement GetHealthStatus() service

Implement GetHealthStatus() service of the EFI Driver Health Protocol

- Make sure only legal state transitions are implemented
- Evaluate configuration data and repair status

- Return HII Strings for message(s) associated with the current state
- If configuration required, return HII Form to be processed

10.10.2.5 Implement Repair() service

Implement Repair() service of the EFI Driver Health Protocol

- Calling Repair Notification callback is optional, but recommended.
- Update health status in private context structure before returning
- Make sure only legal state transitions are implemented

10.11 EFI Adapter Information Protocol

This section provides a detailed description of the **EFI_ADAPTER_INFORMATION_PROTOCOL**. The EFI Adapter Information Protocol is used to dynamically and quickly discover or set device information for an adapter. The discovery of information and state of an adapter should be quick and only return dynamic information. The information should never be cached or stale. The setting information for the adapter should also be fast and simple. The only information that should be set is operating state information, like setting a speed. This protocol is meant to be light weight and non-blocking.

EFI_ADAPTER_INFORMATION_PROTOCOL

SUMMARY

Since this protocol will return and set information for the adapter, the adapter device driver must publish the **EFI_ADAPTER_INFORMATION_PROTOCOL**.

There are many kinds of adapters. The set and get adapter information functions should be used to determine the current state of the adapter, or to set a state for an adapter, like device speed.

GUID

```
#define EFI_ADAPTER_INFORMATION_PROTOCOL_GUID \
  { 0xE5DD1403, 0xD622, 0xC24E, \
    { 0x84, 0x88, 0xC7, 0x1B, 0x17, 0xF5, 0xE8, 0x02 } }
```

Protocol Interface Structure

```
typedef struct _EFI_ADAPTER_INFORMATION_PROTOCOL {
  EFI_ADAPTER_INFO_GET_INFO           GetInformation;
  EFI_ADAPTER_INFO_SET_INFO           SetInformation;
  EFI_ADAPTER_INFO_GET_SUPPORTED_TYPES GetSupportedTypes;
} EFI_ADAPTER_INFORMATION_PROTOCOL;
```

Parameters

<i>GetInformation</i>	Gets device state information from adapter. See GetInformation() for more function description.
<i>SetInformation</i>	Sets device information for adapter. See SetInformation() for more function description.

GetSupportedTypes Gets a list of supported information types for this instance of the protocol.

Description

The **EFI_ADAPTER_INFORMATION_PROTOCOL** is used to get or set the state for an adapter.

EFI_ADAPTER_INFORMATION_PROTOCOL. EFI_ADAPTER_GET_INFO()

Summary

Returns the current state information for the adapter.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ADAPTER_INFO_GET_INFO) (
    IN EFI_ADAPTER_INFORMATION_PROTOCOL *This,
    IN EFI_GUID *InformationType,
    OUT VOID **InformationBlock,
    OUT UINTN *InformationBlockSize
);
```

Parameters

<i>This</i>	A pointer to the EFI_ADAPTER_INFORMATION_PROTOCOL instance.
<i>InformationType</i>	A pointer to an EFI_GUID that defines the contents of <i>InformationBlock</i> . The caller must use the <i>InformationType</i> to specify the information it needs to retrieve from this service and to determine how to parse the <i>InformationBlock</i> . The driver should not attempt to free <i>InformationType</i> .
<i>InformationBlock</i>	This service returns a pointer to the buffer with the <i>InformationBlock</i> structure which contains details about the data specific to <i>InformationType</i> . This structure is defined based on the type of data returned, and will be different for different data types. This service and caller decode this structure and its contents based on <i>InformationType</i> . This buffer is allocated by this service, and it is the responsibility of the caller to free it after using it.
<i>InformationBlockSize</i>	The driver returns the size of the <i>InformationBlock</i> in bytes.

Description

The **GetInformation()** function returns information of type *InformationType* from the adapter. If an adapter does not support the requested informational type, then **EFI_UNSUPPORTED** is returned.

Status Codes Returned

EFI_SUCCESS	The <i>InformationType</i> information was retrieved.
EFI_UNSUPPORTED	The <i>InformationType</i> is not known.

EFI_DEVICE_ERROR	The device reported an error.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources
EFI_INVALID_PARAMETER	<i>This</i> is NULL
EFI_INVALID_PARAMETER	<i>InformationBlock</i> is NULL
EFI_INVALID_PARAMETER	<i>InformationBlockSize</i> is NULL

EFI_ADAPTER_INFORMATION_PROTOCOL. EFI_ADAPTER_INFO_SET_INFO()

Summary

Sets state information for an adapter.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ADAPTER_INFO_SET_INFO) (
    IN EFI_ADAPTER_INFORMATION_PROTOCOL *This,
    IN EFI_GUID *InformationType,
    IN VOID *InformationBlock,
    IN UINTN InformationBlockSize
);
```

Parameters

- This* A pointer to the **EFI_ADAPTER_INFORMATION_PROTOCOL** instance.
- InformationType* A pointer to an **EFI_GUID** that defines the contents of *InformationBlock*. The caller must use the *InformationType* to specify the information it wants the service.
- InformationBlock* A pointer to the *InformationBlock* structure which contains details about the data specific to *InformationType*. This structure is defined based on the type of data sent, and will be different for different data types. The driver and caller decode this structure and its contents based on *InformationType*. This buffer is allocated by the caller. It is the responsibility of the caller to free it after the caller has set the requested parameters.
- InformationBlockSize* The size of the *InformationBlock* in bytes.

Description

The **SetInformation()** function sends information of type *InformationType* for an adapter. If an adapter does not support the requested informational type, then **EFI_UNSUPPORTED** is returned.

Related Definitions

Status Codes Returned

EFI_SUCCESS	The information was received and interpreted successfully.
EFI_UNSUPPORTED	The <i>InformationType</i> is not known.
EFI_DEVICE_ERROR	The device reported an error.
EFI_INVALID_PARAMETER	<i>This</i> is NULL

EFI_INVALID_PARAMETER	<i>InformationBlock</i> is NULL
EFI_WRITE_PROTECTED	The <i>InformationType</i> cannot be modified using EFI_ADAPTER_INFO_SET_INFO()

EFI_ADAPTER_INFORMATION_PROTOCOL. EFI_ADAPTER_INFO_GET_SUPPORTED_TYPES()

Summary

Get a list of supported information types for this instance of the protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ADAPTER_INFO_GET_SUPPORTED_TYPES) (
    IN     EFI_ADAPTER_INFORMATION_PROTOCOL *This,
    OUT    EFI_GUID                        **InfoTypesBuffer,
    OUT    UINTN                          *InfoTypesBufferCount
) ;
```

Parameters

This A pointer to the **EFI_ADAPTER_INFORMATION_PROTOCOL** instance.

InfoTypesBuffer A pointer to the array of *InformationType* GUIDs that are supported by *This*. This buffer is allocated by this service, and it is the responsibility of the caller to free it after using it

InfoTypesBufferCount A pointer to the number of GUIDs present in *InfoTypesBuffer*.

Description

The **GetSupportedTypes()** function returns a list of *InformationType* GUIDs that are supported on an adapter with this instance of **EFI_ADAPTER_INFORMATION_PROTOCOL**. The list is returned in *InfoTypesBuffer*, and the number of GUID pointers in *InfoTypesBuffer* is returned in *InfoTypesBufferCount*.

Status Codes Returned

EFI_SUCCESS	The list of information type GUIDs that are supported on this adapter was returned in <i>InfoTypesBuffer</i> . The number of information type GUIDs was returned in <i>InfoTypesBufferCount</i> .
EFI_INVALID_PARAMETER	<i>This</i> is NULL
EFI_INVALID_PARAMETER	<i>InfoTypesBuffer</i> is NULL
EFI_INVALID_PARAMETER	<i>InfoTypesBufferCount</i> is NULL
EFI_OUT_OF_RESOURCES	There is not enough pool memory to store the results

10.12 EFI Adapter Information Protocol Information Types

Note: In addition to the information block types defined in this section, driver writers may define additional information type blocks for their own use provided all such blocks are each identified by a unique GUID created by the definer.

Clients of the protocol should ignore any unrecognized block types returned by **GetSupportedTypes ()**.

10.12.1 Network Media State

For network adapters, the **EFI_ADAPTER_INFORMATION_PROTOCOL** must be installed on the same handle as the UNDI protocol. If SNP or MNP protocol, instead of the UNDI protocol, is installed on adapter handle, then the **EFI_ADAPTER_INFORMATION_PROTOCOL** must be installed on the same handle as the SNP or MNP protocol.

InformationType

```
#define EFI_ADAPTER_INFO_MEDIA_STATE_GUID \
    {0xD7C74207, 0xA831, 0x4A26 \
     {0xB1, 0xF5, 0xD1, 0x93, 0x06, 0x5C, 0xE8, 0xB6}}
```

Corresponding *InformationBlock*:

```
typedef struct {
    EFI_STATUS      MediaState;
} EFI_ADAPTER_INFO_MEDIA_STATE;
```

<i>MediaState</i>	Returns the current media state status
<i>MediaState</i>	Returns the current media state status. <i>MediaState</i> can have any of the following values: EFI_SUCCESS : There is media attached to the network adapter. EFI_NOT_READY : This detects a bounced state. There was media attached to the network adapter, but it was removed and reattached. EFI_NO_MEDIA : There is not any media attached to the network

10.12.2 Network Boot

For iSCSI and FCoE HBA adapters, the `EFI_ADAPTER_INFORMATION_PROTOCOL` must be installed on the same handle as the `EFI_EXT_SCSI_PASS_THRU_PROTOCOL`.

InformationType

```
#define EFI_ADAPTER_INFO_NETWORK_BOOT_GUID \
  {0x1FBD2960, 0x4130, 0x41E5, \
   {0x94, 0xAC, 0xD2, 0xCF, 0x03, 0x7F, 0xB3, 0x7C}}
```

Corresponding *InformationBlock*:

```
typedef struct {
  BOOLEAN          iScsiIpv4BootCapablity;
  BOOLEAN          iScsiIpv6BootCapablity;
  BOOLEAN          FCoeBootCapablity;
  BOOLEAN          OffloadCapability;
  BOOLEAN          iScsiMpioCapability;
  BOOLEAN          iScsiIpv4Boot;
  BOOLEAN          iScsiIpv6Boot;
  BOOLEAN          FCoeBoot;
} EFI_ADAPTER_INFO_NETWORK_BOOT;
```

iScsiIpv4BootCapablity

TRUE if the adapter supports booting from iSCSI IPv4 targets.

iScsiIpv6BootCapablity

TRUE if the adapter supports booting from iSCSI IPv6 targets.

FCoeBootCapablity

TRUE if the adapter supports booting from FCoE targets.

OffloadCapability

TRUE if the adapter supports an offload engine (such as TCP Offload Engine (TOE) for its iSCSI or FCoE boot operations.

iScsiMpioCapability

TRUE if the adapter supports multipath I/O (MPIO) for its iSCSI boot operations.

iScsiIpv4Boot

TRUE if the adapter is currently configured to boot from iSCSI IPv4 targets.

iScsiIpv6Boot

TRUE if the adapter is currently configured to boot from iSCSI IPv6 targets.

FCoeBoot

TRUE if the adapter is currently configured to boot from FCoE targets.

Note: The adapter should set the *iScsiIpv4BootCapability*, *iScsiIpv6BootCapability*, or *FCoeBootCapability* fields to *TRUE* if it supports that boot capability, even if that capability is currently disabled or not configured.

10.12.3 SAN MAC Address

SUMMARY

Since this instance of a data blocks for a **EFI_ADAPTER_INFORMATION_PROTOCOL** support additional information for ascertaining the SAN MAC address for an FCOE-aware network interface controller. Details on the **Get ()** method.

SAN MAC Address - Get

Note: An instance of the **EFI_ADAPTER_INFORMATION_PROTOCOL** supporting this GUID must be installed on the same handle as the *NI* protocol.

SAN MAC address information

InformationType

```
#define EFI_ADAPTER_INFO_SAN_MAC_ADDRESS_GUID \
{0x114da5ef, 0x2cf1, 0x4e12, \
  {0x9b, 0xbb, 0xc4, 0x70, 0xb5, 0x52, 0x05, 0xd9}}
```

Corresponding *InformationBlock*:

```
typedef struct {
  EFI_MAC_ADDRESS      SanMacAddress;
} EFI_ADAPTER_INFO_SAN_MAC_ADDRESS;
```

SanMacAddress Returns the SAN MAC address for the adapter.

For adapters that support today's 802.3 ethernet networking and Fibre-Channel Over Ethernet (FCOE), this conveys the FCOE SAN MAC address from the adapter

10.12.4 IPV6 Support from UNDI

For network adapters, the **EFI_ADAPTER_INFORMATION_PROTOCOL** must be installed on the same handle as the UNDI protocol.

- *Ipv6Support* returns capability of UNDI to support IPV6 traffic.
- *Ipv6Support* can have any of the following values:
 - TRUE*: The UNDI supports IPV6.
 - FALSE*: This UNDI does not support IPV6 traffic.

InformationType

```
#define EFI_ADAPTER_INFO_UNDI_IPV6_SUPPORT_GUID \  
{ 0x4bd56be3, 0x4975, 0x4d8a, \  
{0xa0, 0xad, 0xc4, 0x91, 0x20, 0x4b, 0x5d, 0x4d}}
```

Corresponding *InformationBlock*:

```
typedef struct {  
    BOOLEAN Ipv6Support;  
} EFI_ADAPTER_INFO_UNDI_IPV6_SUPPORT;
```

Protocols — Console Support

This section explores console support protocols, including Simple Text Input, Simple Text Output, Simple Pointer, Serial IO, and Graphics Output protocols.

11.1 Console I/O Protocol

This section defines the Console I/O protocol. This protocol is used to handle input and output of text-based information intended for the system user during the operation of code in the boot services environment. Also included here are the definitions of three console devices: one for input and one each for normal output and errors.

These interfaces are specified by function call definitions to allow maximum flexibility in implementation. For example, there is no requirement for compliant systems to have a keyboard or screen directly connected to the system. Implementations may choose to direct information passed using these interfaces in arbitrary ways provided that the semantics of the functions are preserved (in other words, provided that the information is passed to and from the system user).

11.1.1 Overview

The UEFI console is built out of the [EFI_SIMPLE_TEXT_INPUT_PROTOCOL](#) and the [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#). These two protocols implement a basic text-based console that allows platform firmware, applications written to this specification, and UEFI OS loaders to present information to and receive input from a system administrator. The UEFI console supported 16-bit Unicode character codes, a simple set of input control characters (Scan Codes), and a set of output-oriented programmatic interfaces that give functionality equivalent to an intelligent terminal. The console does not support pointing devices on input or bitmaps on output.

This specification requires that the [EFI_SIMPLE_TEXT_INPUT_PROTOCOL](#) support the same languages as the corresponding [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#). The [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) is recommended to support at least the printable Basic Latin Unicode character set to enable standard terminal emulation software to be used with an EFI console. The Basic Latin Unicode character set implements a superset of ASCII that has been extended to 16-bit characters. Any number of other Unicode character sets may be optionally supported.

11.1.2 ConsoleIn Definition

The [EFI_SIMPLE_TEXT_INPUT_PROTOCOL](#) defines an input stream that contains Unicode characters and required EFI scan codes. Only the control characters defined in [Table 99](#) have meaning in the Unicode input or output streams. The control characters are defined to be characters U+0000 through U+001F. The input stream does not support any software flow control.

Table 99. Supported Unicode Control Characters

Mnemonic	Unicode	Description
Null	U+0000	Null character ignored when received.
BS	U+0008	Backspace. Moves cursor left one column. If the cursor is at the left margin, no action is taken.
TAB	U+0x0009	Tab.
LF	U+000A	Linefeed. Moves cursor to the next line.
CR	U+000D	Carriage Return. Moves cursor to left margin of the current line.

The input stream supports Scan Codes in addition to Unicode characters. If the Scan Code is set to 0x00 then the Unicode character is valid and should be used. If the Scan Code is set to a non-0x00 value it represents a special key as defined by [Table 100](#).

Table 100. EFI Scan Codes for `EFI_SIMPLE_TEXT_INPUT_PROTOCOL`

EFI Scan Code	Description
0x00	Null scan code.
0x01	Move cursor up 1 row.
0x02	Move cursor down 1 row.
0x03	Move cursor right 1 column.
0x04	Move cursor left 1 column.
0x05	Home.
0x06	End.
0x07	Insert.
0x08	Delete.
0x09	Page Up.
0x0a	Page Down.
0x0b	Function 1.
0x0c	Function 2.
0x0d	Function 3.
0x0e	Function 4.
0x0f	Function 5.
0x10	Function 6.
0x11	Function 7.
0x12	Function 8.
0x13	Function 9.
0x14	Function 10.
0x17	Escape.

Table 101. EFI Scan Codes for `EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL`

EFI Scan Code	Description
0x15	Function 11
0x16	Function 12
0x68	Function 13
0x69	Function 14
0x6A	Function 15
0x6B	Function 16
0x6C	Function 17
0x6D	Function 18
0x6E	Function 19
0x6F	Function 20
0x70	Function 21
0x71	Function 22
0x72	Function 23
0x73	Function 24
0x7F	Mute
0x80	Volume Up
0x81	Volume Down
0x100	Brightness Up

11.2 Simple Text Input Ex Protocol

The Simple Text Input Ex protocol defines an extension to the Simple Text Input protocol which enables various new capabilities described in this section.

EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL

Summary

This protocol is used to obtain input from the *ConsoleIn* device. The EFI specification requires that the **EFI_SIMPLE_TEXT_INPUT_PROTOCOL** supports the same languages as the corresponding **EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL**.

GUID

```
#define EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL_GUID \
    {0xdd9e7534, 0x7762, 0x4698, \
     0x8c, 0x14, 0xf5, 0x85, 0x17, 0xa6, 0x25, 0xaa}
```

Protocol Interface Structure

```
typedef struct _EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL{
    EFI_INPUT_RESET_EX                Reset;
    EFI_INPUT_READ_KEY_EX             ReadKeyStrokeEx;
    EFI_EVENT                          WaitForKeyEx;
    EFI_SET_STATE                      SetState;
    EFI_REGISTER_KEYSTROKE_NOTIFY     RegisterKeyNotify;
    EFI_UNREGISTER_KEYSTROKE_NOTIFY   UnregisterKeyNotify;
} EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL;
```

Parameters

<i>Reset</i>	Reset the <i>ConsoleIn</i> device. See Reset() .
<i>ReadKeyStrokeEx</i>	Returns the next input character. See <i>ReadKeyStrokeEx()</i> .
<i>WaitForKeyEx</i>	Event to use with <i>WaitForEvent()</i> to wait for a key to be available. An Event will only be triggered if <i>KeyData.Key</i> has information contained within it.
<i>SetState</i>	Set the EFI_KEY_TOGGLE_STATE state settings for the input device.
<i>RegisterKeyNotify</i>	Register a notification function to be called when a given key sequence is hit.
<i>UnregisterKeyNotify</i>	Removes a specific notification function.

Description

The **EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL** is used on the *ConsoleIn* device. It is an extension to the Simple Text Input protocol which allows a variety of extended shift state information to be returned.

EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.Reset()

Summary

Resets the input device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INPUT_RESET_EX) (
    IN EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL *This,
    IN BOOLEAN ExtendedVerification
);
```

Parameters

This A pointer to the **EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL** instance. Type **EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL** is defined in this section.

ExtendedVerification Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The **Reset()** function resets the input device hardware.

The implementation of Reset is required to clear the contents of any input queues resident in memory used for buffering keystroke data and put the input stream in a known empty state.

As part of initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the *ExtendedVerification* flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The device was reset.
EFI_DEVICE_ERROR	The device is not functioning correctly and could not be reset.

EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.ReadKeyStrokeEx()

Summary

Reads the next keystroke from the input device.

```

Prototype
typedef
EFI_STATUS
(EFIAPI *EFI_INPUT_READ_KEY_EX) (
    IN EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL    *This,
    OUT EFI_KEY_DATA                        *KeyData
);
    
```

Parameters

<i>This</i>	A pointer to the EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL instance. Type EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL is defined in this section.
<i>KeyData</i>	A pointer to a buffer that is filled in with the keystroke state data for the key that was pressed. Type EFI_KEY_DATA is defined in "Related Definitions" below.

Related Definitions

```

//*****
// EFI_KEY_DATA
//*****
typedef struct {
    EFI_INPUT_KEY        Key;
    EFI_KEY_STATE        KeyState;
} EFI_KEY_DATA
    
```

<i>Key</i>	The EFI scan code and Unicode value returned from the input device.
<i>KeyState</i>	The current state of various toggled attributes as well as input modifier values.

```

//*****
// EFI_KEY_STATE
//*****
//
// Any Shift or Toggle State that is valid should have
// high order bit set.
//
typedef struct EFI_KEY_STATE {
    UINT32                KeyShiftState;
    EFI_KEY_TOGGLE_STATE  KeyToggleState;
} EFI_KEY_STATE;

```

KeyShiftState Reflects the currently pressed shift modifiers for the input device. The returned value is valid only if the high order bit has been set.

KeyToggleState Reflects the current internal state of various toggled attributes. The returned value is valid only if the high order bit has been set.

```

#define EFI_SHIFT_STATE_VALID          0x80000000
#define EFI_RIGHT_SHIFT_PRESSED        0x00000001
#define EFI_LEFT_SHIFT_PRESSED         0x00000002
#define EFI_RIGHT_CONTROL_PRESSED      0x00000004
#define EFI_LEFT_CONTROL_PRESSED       0x00000008
#define EFI_RIGHT_ALT_PRESSED          0x00000010
#define EFI_LEFT_ALT_PRESSED           0x00000020
#define EFI_RIGHT_LOGO_PRESSED         0x00000040
#define EFI_LEFT_LOGO_PRESSED          0x00000080
#define EFI_MENU_KEY_PRESSED           0x00000100
#define EFI_SYS_REQ_PRESSED            0x00000200

//*****
// EFI_KEY_TOGGLE_STATE
//*****
typedef UINT8                EFI_KEY_TOGGLE_STATE;

#define EFI_TOGGLE_STATE_VALID         0x80
#define EFI_KEY_STATE_EXPOSED          0x40
#define EFI_SCROLL_LOCK_ACTIVE        0x01
#define EFI_NUM_LOCK_ACTIVE            0x02
#define EFI_CAPS_LOCK_ACTIVE           0x04

```

Description

The **ReadKeyStrokeEx()** function reads the next keystroke from the input device. If there is no pending keystroke the function returns **EFI_NOT_READY**. If there is a pending keystroke, then *KeyData.Key.ScanCode* is the EFI scan code defined in [Table 100](#). The *KeyData.Key.UnicodeChar* is the actual printable character or is zero if the key does not represent a printable character (control key, function key, etc.). The *KeyData.KeyState* is the

modifier shift state for the character reflected in *KeyData.Key.UnicodeChar* or *KeyData.Key.ScanCode*. This function mirrors the behavior of **ReadKeyStroke** (in the Simple Input Protocol in that a keystroke will only be returned when *KeyData.Key* has data within it.

When interpreting the data from this function, it should be noted that if a class of printable characters that are normally adjusted by shift modifiers (e.g. Shift Key + "f" key) would be presented solely as a *KeyData.Key.UnicodeChar* without the associated shift state. So in the previous example of a Shift Key + "f" key being pressed, the only pertinent data returned would be *KeyData.Key.UnicodeChar* with the value of "F". This of course would not typically be the case for non-printable characters such as the pressing of the Right Shift Key + F10 key since the corresponding returned data would be reflected both in the *KeyData.KeyState.KeyShiftState* and *KeyData.Key.ScanCode* values.

UEFI drivers which implement the **EFI_SIMPLE_TEXT_INPUT_EX** protocol are required to return *KeyData.Key* and *KeyData.KeyState* values. These drivers must always return the most current state of *KeyData.KeyState.KeyShiftState* and *KeyData.KeyState.KeyToggleState*. It should also be noted that certain input devices may not be able to produce shift or toggle state information, and in those cases the high order bit in the respective Toggle and Shift state fields should not be active.

If the **EFI_KEY_STATE_EXPOSED** bit is turned on, then this instance of the **EFI_SIMPLE_INPUT_EX_PROTOCOL** supports the ability to return partial keystrokes. With **EFI_KEY_STATE_EXPOSED** bit enabled, the **ReadKeyStrokeEx** function will allow the return of incomplete keystrokes such as the holding down of certain keys which are expressed as a part of *KeyState* when there is no *Key* data.

Status Codes Returned

EFI_SUCCESS	The keystroke information was returned.
EFI_NOT_READY	There was no keystroke data available.
EFI_DEVICE_ERROR	The keystroke information was not returned due to hardware errors.

EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.SetState()

Summary

Set certain state for the input device.

Prototype

```
typedef
    EFI_STATUS
    (EFI_API *EFI_SET_STATE) (
        IN EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL    *This,
        IN EFI_KEY_TOGGLE_STATE                 *KeyToggleState
    );
```

Parameters

<i>This</i>	A pointer to the EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL instance. Type EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL is defined in this section.
<i>KeyToggleState</i>	Pointer to the EFI_KEY_TOGGLE_STATE to set the state for the input device. Type EFI_KEY_TOGGLE_STATE is defined in "Related Definitions" for EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.ReadKeyStrokeEx() , above.

The SetState() function allows the input device hardware to have state settings adjusted. By calling the SetState() function with the **EFI_KEY_STATE_EXPOSED** bit active in the *KeyToggleState* parameter, this will enable the **ReadKeyStrokeEx** function to return incomplete keystrokes such as the holding down of certain keys which are expressed as a part of KeyState when there is no Key data.

Status Codes Returned

EFI_SUCCESS	The device state was set appropriately.
EFI_DEVICE_ERROR	The device is not functioning correctly and could not have the setting adjusted.
EFI_UNSUPPORTED	The device does not support the ability to have its state set or the requested state change was not supported.

EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.RegisterKeyNotify()

Summary

Register a notification function for a particular keystroke for the input device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_REGISTER_KEYSTROKE_NOTIFY) (
    IN EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL *This,
    IN EFI_KEY_DATA *KeyData,
    IN EFI_KEY_NOTIFY_FUNCTION KeyNotificationFunction,
    OUT VOID **NotifyHandle
);
```

Parameters

<i>This</i>	A pointer to the EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL instance. Type EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL is defined in this section.
<i>KeyData</i>	A pointer to a buffer that is filled in with the keystroke information for the key that was pressed.
<i>KeyNotificationFunction</i>	Points to the function to be called when the key sequence is typed specified by <i>KeyData</i> . See EFI_KEY_NOTIFY_FUNCTION below.
<i>NotifyHandle</i>	Points to the unique handle assigned to the registered notification.

Description

The **RegisterKeystrokeNotify()** function registers a function which will be called when a specified keystroke will occur. The keystroke being specified can be for any combination of *KeyData.Key* or *KeyData.KeyState* information.

Related Definitions

```
/**
//*****
// EFI_KEY_NOTIFY
//*****
typedef
EFI_STATUS
(EFIAPI *EFI_KEY_NOTIFY_FUNCTION) (
    IN EFI_KEY_DATA *KeyData
);
```

Status Codes Returned

EFI_SUCCESS	The device state was set appropriately.
-------------	---

EFI_OUT_OF_RESOURCES	Unable to allocate necessary data structures.
----------------------	---

EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.UnregisterKeyNotify()

Summary

Set certain state for the input device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_UNREGISTER_KEYSTROKE_NOTIFY) (
    IN EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL *This,
    IN VOID *NotificationHandle
);
```

Parameters

This A pointer to the **EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL** instance. Type **EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL** is defined in this section.

NotificationHandle The handle of the notification function being unregistered.

Description

The **UnregisterKeystrokeNotify()** function removes the notification which was previously registered.

Status Codes Returned

EFI_SUCCESS	The device state was set appropriately.
EFI_INVALID_PARAMETER	The NotificationHandle is invalid.

11.3 Simple Text Input Protocol

The Simple Text Input protocol defines the minimum input required to support the *ConsoleIn* device.

EFI_SIMPLE_TEXT_INPUT_PROTOCOL

Summary

This protocol is used to obtain input from the *ConsoleIn* device. The EFI specification requires that the **EFI_SIMPLE_TEXT_INPUT_PROTOCOL** supports the same languages as the corresponding [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#).

GUID

```
#define EFI_SIMPLE_TEXT_INPUT_PROTOCOL_GUID \
{0x387477c1,0x69c7,0x11d2,\
 {0x8e,0x39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Protocol Interface Structure

```
typedef struct _EFI_SIMPLE_TEXT_INPUT_PROTOCOL {
    EFI_INPUT_RESET      Reset;
    EFI_INPUT_READ_KEY   ReadKeyStroke;
    EFI_EVENT             WaitForKey;
} EFI_SIMPLE_TEXT_INPUT_PROTOCOL;
```

Parameters

<i>Reset</i>	Reset the <i>ConsoleIn</i> device. See Reset() .
<i>ReadKeyStroke</i>	Returns the next input character. See ReadKeyStroke() .
<i>WaitForKey</i>	Event to use with EFI_BOOT_SERVICES.WaitForEvent() to wait for a key to be available.

Description

The **EFI_SIMPLE_TEXT_INPUT_PROTOCOL** is used on the *ConsoleIn* device. It is the minimum required protocol for *ConsoleIn*.

EFI_SIMPLE_TEXT_INPUT_PROTOCOL.Reset()

Summary

Resets the input device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INPUT_RESET) (
    IN EFI_SIMPLE_TEXT_INPUT_PROTOCOL    *This,
    IN BOOLEAN                            ExtendedVerification
);
```

Parameters

This A pointer to the [EFI_SIMPLE_TEXT_INPUT_PROTOCOL](#) instance. Type [EFI_SIMPLE_TEXT_INPUT_PROTOCOL](#) is defined in [Section 11.3](#)

ExtendedVerification Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The **Reset()** function resets the input device hardware.

The implementation of Reset is required to clear the contents of any input queues resident in memory used for buffering keystroke data and put the input stream in a known empty state.

As part of initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the *ExtendedVerification* flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The device was reset.
EFI_DEVICE_ERROR	The device is not functioning correctly and could not be reset.

EFI_SIMPLE_TEXT_INPUT_PROTOCOL.ReadKeyStroke()

Summary

Reads the next keystroke from the input device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INPUT_READ_KEY) (
    IN EFI_SIMPLE_TEXT_INPUT_PROTOCOL *This,
    OUT EFI_INPUT_KEY *Key
);
```

Parameters

This A pointer to the [EFI SIMPLE TEXT INPUT PROTOCOL](#) instance. Type [EFI_SIMPLE_TEXT_INPUT_PROTOCOL](#) is defined in [Section 11.3](#).

Key A pointer to a buffer that is filled in with the keystroke information for the key that was pressed. Type [EFI_INPUT_KEY](#) is defined in “Related Definitions” below.

```
Related Definitions
//*****
// EFI_INPUT_KEY
//*****
typedef struct {
    UINT16 ScanCode;
    CHAR16 UnicodeChar;
} EFI_INPUT_KEY;
```

Description

The **ReadKeyStroke()** function reads the next keystroke from the input device. If there is no pending keystroke the function returns **EFI_NOT_READY**. If there is a pending keystroke, then *ScanCode* is the EFI scan code defined in [Table 100](#). The *UnicodeChar* is the actual printable character or is zero if the key does not represent a printable character (control key, function key, etc.).

Status Codes Returned

EFI_SUCCESS	The keystroke information was returned.
EFI_NOT_READY	There was no keystroke data available.
EFI_DEVICE_ERROR	The keystroke information was not returned due to hardware errors.

11.3.1 ConsoleOut or StandardError

The **EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL** must implement the same Unicode code pages as the **EFI_SIMPLE_TEXT_INPUT_PROTOCOL**. The protocol must also support the Unicode

control characters defined in [Table 99](#). The `EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL` supports special manipulation of the screen by programmatic methods and therefore does not support the EFI scan codes defined in [Table 100](#).

11.4 Simple Text Output Protocol

The Simple Text Output protocol defines the minimum requirements for a text-based *ConsoleOut* device. The EFI specification requires that the `EFI_SIMPLE_TEXT_INPUT_PROTOCOL` support the same languages as the corresponding `EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL`.

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL

Summary

This protocol is used to control text-based output devices.

GUID

```
#define EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL_GUID \
    {0x387477c2,0x69c7,0x11d2,\
     {0x8e,0x39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Protocol Interface Structure

```
typedef struct _EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL {
    EFI_TEXT_RESET           Reset;
    EFI_TEXT_STRING         OutputString;
    EFI_TEXT_TEST_STRING    TestString;
    EFI_TEXT_QUERY_MODE     QueryMode;
    EFI_TEXT_SET_MODE       SetMode;
    EFI_TEXT_SET_ATTRIBUTE  SetAttribute;
    EFI_TEXT_CLEAR_SCREEN   ClearScreen;
    EFI_TEXT_SET_CURSOR_POSITION SetCursorPosition;
    EFI_TEXT_ENABLE_CURSOR  EnableCursor;
    SIMPLE_TEXT_OUTPUT_MODE *Mode;
} EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL;
```

Parameters

<i>Reset</i>	Reset the <i>ConsoleOut</i> device. See Reset() .
<i>OutputString</i>	Displays the string on the device at the current cursor location. See OutputString() .
<i>TestString</i>	Tests to see if the <i>ConsoleOut</i> device supports this string. See TestString() .
<i>QueryMode</i>	Queries information concerning the output device's supported text mode. See QueryMode() .
<i>SetMode</i>	Sets the current mode of the output device. See SetMode() .
<i>SetAttribute</i>	Sets the foreground and background color of the text that is output. See SetAttribute() .

<i>ClearScreen</i>	Clears the screen with the currently set background color. See ClearScreen() .
<i>SetCursorPosition</i>	Sets the current cursor position. See SetCursorPosition() .
<i>EnableCursor</i>	Turns the visibility of the cursor on/off. See EnableCursor() .
<i>Mode</i>	Pointer to SIMPLE_TEXT_OUTPUT_MODE data. Type SIMPLE_TEXT_OUTPUT_MODE is defined in “Related Definitions” below.

The following data values in the **SIMPLE_TEXT_OUTPUT_MODE** interface are read-only and are changed by using the appropriate interface functions:

<i>MaxMode</i>	The number of modes supported by QueryMode() and SetMode() .
<i>Mode</i>	The text mode of the output device(s).
<i>Attribute</i>	The current character output attribute.
<i>CursorColumn</i>	The cursor’s column.
<i>CursorRow</i>	The cursor’s row.
<i>CursorVisible</i>	The cursor is currently visible or not.

Related Definitions

```

//*****
// SIMPLE_TEXT_OUTPUT_MODE
//*****
typedef struct {
    INT32                               MaxMode;
    // current settings
    INT32                               Mode;
    INT32                               Attribute;
    INT32                               CursorColumn;
    INT32                               CursorRow;
    BOOLEAN                             CursorVisible;
} SIMPLE_TEXT_OUTPUT_MODE;

```

Description

The **SIMPLE_TEXT_OUTPUT** protocol is used to control text-based output devices. It is the minimum required protocol for any handle supplied as the *ConsoleOut* or *StandardError* device. In addition, the minimum supported text mode of such devices is at least 80 x 25 characters. A video device that only supports graphics mode is required to emulate text mode functionality. Output strings themselves are not allowed to contain any control codes other than those defined in [Table 99](#). Positional cursor placement is done only via the [SetCursorPosition\(\)](#) function. It is highly recommended that text output to the *StandardError* device be limited to sequential string outputs. (That is, it is not recommended to use [ClearScreen\(\)](#) or [SetCursorPosition\(\)](#) on output messages to *StandardError*.)

If the output device is not in a valid text mode at the time of the [EFI_BOOT_SERVICES.HandleProtocol\(\)](#) call, the device is to indicate that its *CurrentMode* is -1 . On connecting to the output device the caller is required to verify the mode of the output device, and if it is not acceptable to set it to something it can use.

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.Reset()

Summary

Resets the text output device hardware.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_TEXT_RESET) (
    IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL *This,
    IN BOOLEAN ExtendedVerification
);
```

Parameters

This A pointer to the [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) instance. Type [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) is defined in the “Related Definitions” of [Section 11.4](#).

ExtendedVerification Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The **Reset()** function resets the text output device hardware. The cursor position is set to (0, 0), and the screen is cleared to the default background color for the output device.

As part of initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the *ExtendedVerification* flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The text output device was reset.
EFI_DEVICE_ERROR	The text output device is not functioning correctly and could not be reset.

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.OutputString()

Summary

Writes a string to the output device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_STRING) (
    IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL  *This,
    IN CHAR16                           *String
);
```

Parameters

This

A pointer to the [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) instance. Type [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) is defined in the “Related Definitions” of [Section 11.4](#).

String

The Null-terminated string to be displayed on the output device(s). All output devices must also support the Unicode drawing character codes defined in “Related Definitions.”

Related Definitions

```

Description

The [OutputString\(\)](#) function writes a string to the output device. This is the most basic output mechanism on an output device. The *String* is displayed at the current cursor location on the output device(s) and the cursor is advanced according to the rules listed in [Table 102](#).

Table 102. EFI Cursor Location/Advance Rules

Mnemonic	Unicode	Description
Null	U+0000	Ignore the character, and do not move the cursor.
BS	U+0008	If the cursor is not at the left edge of the display, then move the cursor left one column.
LF	U+000A	If the cursor is at the bottom of the display, then scroll the display one row, and do not update the cursor position. Otherwise, move the cursor down one row.
CR	U+000D	Move the cursor to the beginning of the current row.

Mnemonic	Unicode	Description
Other	U+XXXX	Print the character at the current cursor position and move the cursor right one column. If this moves the cursor past the right edge of the display, then the line should wrap to the beginning of the next line. This is equivalent to inserting a CR and an LF. Note that if the cursor is at the bottom of the display, and the line wraps, then the display will be scrolled one line.

Note: *If desired, the system's NVRAM environment variables may be used at install time to determine the configured locale of the system or the installation procedure can query the user for the proper language support. This is then used to either install the proper EFI image/loader or to configure the installed image's strings to use the proper text for the selected locale.*

Status Codes Returned

EFI_SUCCESS	The string was output to the device.
EFI_DEVICE_ERROR	The device reported an error while attempting to output the text.
EFI_UNSUPPORTED	The output device's mode is not currently in a defined text mode.
EFI_WARN_UNKNOWN_GLYPH	This warning code indicates that some of the characters in the string could not be rendered and were skipped.

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.TestString()

Summary

Verifies that all characters in a string can be output to the target device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_TEST_STRING) (
    IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL *This,
    IN CHAR16 *String
);
```

Parameters

<i>This</i>	A pointer to the EFI SIMPLE TEXT OUTPUT PROTOCOL instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the “Related Definitions” of Section 11.4 .
<i>String</i>	The Null-terminated string to be examined for the output device(s).

Description

The **TestString()** function verifies that all characters in a string can be output to the target device.

This function provides a way to know if the desired character codes are supported for rendering on the output device(s). This allows the installation procedure (or EFI image) to at least select character codes that the output devices are capable of displaying. Since the output device(s) may be changed between boots, if the loader cannot adapt to such changes it is recommended that the loader call [OutputString\(\)](#) with the text it has and ignore any “unsupported” error codes. Devices that are capable of displaying the Unicode character codes will do so.

Status Codes Returned

EFI_SUCCESS	The device(s) are capable of rendering the output string.
EFI_UNSUPPORTED	Some of the characters in the string cannot be rendered by one or more of the output devices mapped by the EFI handle.

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.QueryMode()

Summary

Returns information for an available text mode that the output device(s) supports.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_QUERY_MODE) (
    IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL  *This,
    IN UINTN                             ModeNumber,
    OUT UINTN                             *Columns,
    OUT UINTN                             *Rows
);
```

Parameters

<i>This</i>	A pointer to the EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the “Related Definitions” of Section 11.4 .
<i>ModeNumber</i>	The mode number to return information on.
<i>Columns, Rows</i>	Returns the geometry of the text output device for the request <i>ModeNumber</i> .

Description

The **QueryMode()** function returns information for an available text mode that the output device(s) supports.

It is required that all output devices support at least 80x25 text mode. This mode is defined to be mode 0. If the output devices support 80x50, that is defined to be mode 1. All other text dimensions supported by the device will follow as modes 2 and above. If an output device supports modes 2 and above, but does not support 80x50, then querying for mode 1 will return **EFI_UNSUPPORTED**.

Status Codes Returned

EFI_SUCCESS	The requested mode information was returned.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.
EFI_UNSUPPORTED	The mode number was not valid.

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetMode()

Summary

Sets the output device(s) to a specified mode.

Prototype

```
typedef
EFI_STATUS
(* EFI_API EFI_TEXT_SET_MODE) (
    IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL *This,
    IN UINTN ModeNumber
);
```

Parameters

<i>This</i>	A pointer to the EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the “Related Definitions” of Section 11.4 .
<i>ModeNumber</i>	The text mode to set.

Description

The **SetMode ()** function sets the output device(s) to the requested mode. On success the device is in the geometry for the requested mode, and the device has been cleared to the current background color with the cursor at (0,0).

Status Codes Returned

EFI_SUCCESS	The requested text mode was set.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.
EFI_UNSUPPORTED	The mode number was not valid.

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetAttribute()

Summary

Sets the background and foreground colors for the [OutputString\(\)](#) and [ClearScreen\(\)](#) functions.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_SET_ATTRIBUTE) (
    IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL  *This,
    IN UINTN                             Attribute
);
```

Parameters

This

A pointer to the [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) instance. Type [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) is defined in the “Related Definitions” of [Section 11.4](#).

Attribute

The attribute to set. Bits 0..3 are the foreground color, and bits 4..6 are the background color. All other bits are reserved. See “Related Definitions” below.

Related Definitions

```

//*****
// Attributes
//*****
#define EFI_BLACK                0x00
#define EFI_BLUE                 0x01

#define EFI_LIGHTMAGENTA         0x0D
#define EFI_YELLOW               0x0E
#define EFI_WHITE                0x0F

#define EFI_BACKGROUND_BLACK     0x00
#define EFI_BACKGROUND_BLUE      0x10
#define EFI_BACKGROUND_GREEN     0x20
#define EFI_BACKGROUND_CYAN      0x30
#define EFI_BACKGROUND_RED       0x40
#define EFI_BACKGROUND_MAGENTA   0x50
#define EFI_BACKGROUND_BROWN     0x60
#define EFI_BACKGROUND_LIGHTGRAY 0x70

//
// Macro to accept color values in their raw form to create
// a value that represents both a foreground and background
// color in a single byte.
// For Foreground, and EFI_* value is valid from EFI_BLACK(0x00)
// to EFI_WHITE (0x0F).
// For Background, only EFI_BLACK, EFI_BLUE, EFI_GREEN,
// EFI_CYAN, EFI_RED, EFI_MAGENTA, EFI_BROWN, and EFI_LIGHTGRAY
// are acceptable.
//
// Do not use EFI_BACKGROUND_*** values with this macro.
// #define EFI_TEXT_ATTR(Foreground,Background) \
((Foreground) | ((Background) << 4))

```

Description

The `SetAttribute()` function sets the background and foreground colors for the [OutputString\(\)](#) and [ClearScreen\(\)](#) functions.

The color mask can be set even when the device is in an invalid text mode.

Devices supporting a different number of text colors are required to emulate the above colors to the best of the device's capabilities.

Status Codes Returned

EFI_SUCCESS	The requested attributes were set.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.ClearScreen()

Summary

Clears the output device(s) display to the currently selected background color.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_CLEAR_SCREEN) (
    IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL    *This
);
```

Parameters

This A pointer to the [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) instance. Type [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) is defined in the “Related Definitions” of [Section 11.4](#).

Description

The **ClearScreen()** function clears the output device(s) display to the currently selected background color. The cursor position is set to (0, 0).

Status Codes Returned

EFI_SUCCESS	The operation completed successfully.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.
EFI_UNSUPPORTED	The output device is not in a valid text mode.

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetCursorPosition()

Summary

Sets the current coordinates of the cursor position.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_SET_CURSOR_POSITION) (
    IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL *This,
    IN UINTN                            Column,
    IN UINTN                            Row
);
```

Parameters

<i>This</i>	A pointer to the EFI SIMPLE TEXT OUTPUT PROTOCOL instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the “Related Definitions” of Section 11.4 .
<i>Column, Row</i>	The position to set the cursor to. Must greater than or equal to zero and less than the number of columns and rows returned by QueryMode () .

Description

The [SetCursorPosition\(\)](#) function sets the current coordinates of the cursor position. The upper left corner of the screen is defined as coordinate (0, 0).

Status Codes Returned

EFI_SUCCESS	The operation completed successfully.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.
EFI_UNSUPPORTED	The output device is not in a valid text mode, or the cursor position is invalid for the current mode.

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.EnableCursor()

Summary

Makes the cursor visible or invisible.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_ENABLE_CURSOR) (
    IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL *This,
    IN BOOLEAN Visible
);
```

Parameters

This

A pointer to the [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) instance. Type [EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL](#) is defined in the “Related Definitions” of [Section 11.4](#).

Visible

If **TRUE**, the cursor is set to be visible. If **FALSE**, the cursor is set to be invisible.

Description

The **EnableCursor ()** function makes the cursor visible or invisible.

Status Codes Returned

EFI_SUCCESS	The operation completed successfully.
EFI_DEVICE_ERROR	The device had an error and could not complete the request or the device does not support changing the cursor mode.
EFI_UNSUPPORTED	The output device does not support visibility control of the cursor.

11.5 Simple Pointer Protocol

This section defines the Simple Pointer Protocol and a detailed description of the [EFI_SIMPLE_POINTER_PROTOCOL](#). The intent of this section is to specify a simple method for accessing pointer devices. This would include devices such as mice and trackballs.

The [EFI_SIMPLE_POINTER_PROTOCOL](#) allows information about a pointer device to be retrieved. This would include the status of buttons and the motion of the pointer device since the last time it was accessed. This protocol is attached the device handle of a pointer device, and can be used for input from the user in the preboot environment.

EFI_SIMPLE_POINTER_PROTOCOL

Summary

Provides services that allow information about a pointer device to be retrieved.

GUID

```
#define EFI_SIMPLE_POINTER_PROTOCOL_GUID \
    {0x31878c87,0xb75,0x11d5,\
     {0x9a,0x4f,0x00,0x90,0x27,0x3f,0xc1,0x4d}}
```

Protocol Interface Structure

```
typedef struct _EFI_SIMPLE_POINTER_PROTOCOL {
    EFI_SIMPLE_POINTER_RESET      Reset;
    EFI_SIMPLE_POINTER_GET_STATE  GetState;
    EFI_EVENT                     WaitForInput;
    EFI_SIMPLE_INPUT_MODE         *Mode;
} EFI_SIMPLE_POINTER_PROTOCOL;
```

Parameters

<i>Reset</i>	Resets the pointer device. See the Reset() function description.
<i>GetState</i>	Retrieves the current state of the pointer device. See the GetState() function description.
<i>WaitForInput</i>	Event to use with EFI_BOOT_SERVICES.WaitForEvent() to wait for input from the pointer device.
<i>Mode</i>	Pointer to EFI_SIMPLE_POINTER_MODE data. The type EFI_SIMPLE_POINTER_MODE is defined in “Related Definitions” below.

Related Definitions

```
/**
 *
 *
 */
// EFI_SIMPLE_POINTER_MODE
/**
 *
 *
 */
typedef struct {
    UINT64      ResolutionX;
    UINT64      ResolutionY;
    UINT64      ResolutionZ;
    BOOLEAN     LeftButton;
    BOOLEAN     RightButton;
} EFI_SIMPLE_POINTER_MODE;
```

The following data values in the [EFI_SIMPLE_POINTER_MODE](#) interface are read-only and are changed by using the appropriate interface functions:

<i>ResolutionX</i>	The resolution of the pointer device on the x-axis in counts/mm. If 0, then the pointer device does not support an x-axis.
<i>ResolutionY</i>	The resolution of the pointer device on the y-axis in counts/mm. If 0, then the pointer device does not support a y-axis.
<i>ResolutionZ</i>	The resolution of the pointer device on the z-axis in counts/mm. If 0, then the pointer device does not support a z-axis.

<i>LeftButton</i>	TRUE if a left button is present on the pointer device. Otherwise FALSE .
<i>RightButton</i>	TRUE if a right button is present on the pointer device. Otherwise FALSE .

Description

The **EFI_SIMPLE_POINTER_PROTOCOL** provides a set of services for a pointer device that can be used as an input device from an application written to this specification. The services include the ability to reset the pointer device, retrieve the state of the pointer device, and retrieve the capabilities of the pointer device.

EFI_SIMPLE_POINTER_PROTOCOL.Reset()

Summary

Resets the pointer device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_POINTER_RESET) (
    IN EFI_SIMPLE_POINTER_PROTOCOL *This,
    IN BOOLEAN                      ExtendedVerification
);
```

Parameters

This A pointer to the **EFI_SIMPLE_POINTER_PROTOCOL** instance. Type **EFI_SIMPLE_POINTER_PROTOCOL** is defined in [Section 11.5](#).

ExtendedVerification Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

This **Reset()** function resets the pointer device hardware.

As part of initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the *ExtendedVerification* flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The device was reset.
EFI_DEVICE_ERROR	The device is not functioning correctly and could not be reset.

EFI_SIMPLE_POINTER_PROTOCOL.GetState()

Summary

Retrieves the current state of a pointer device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_POINTER_GET_STATE)
  IN EFI_SIMPLE_POINTER_PROTOCOL  *This,
  IN OUT EFI_SIMPLE_POINTER_STATE *State
);
```

Parameters

<i>This</i>	A pointer to the EFI_SIMPLE_POINTER_PROTOCOL instance. Type EFI_SIMPLE_POINTER_PROTOCOL is defined in Section 11.5 .
<i>State</i>	A pointer to the state information on the pointer device. Type EFI_SIMPLE_POINTER_STATE is defined in “Related Definitions” below.

Related Definitions

```

//*****
// EFI_SIMPLE_POINTER_STATE
//*****
typedef struct {
  INT32      RelativeMovementX;
  INT32      RelativeMovementY;
  INT32      RelativeMovementZ;
  BOOLEAN    LeftButton;
  BOOLEAN    RightButton;
} EFI_SIMPLE_POINTER_STATE;
```

RelativeMovementX The signed distance in counts that the pointer device has been moved along the x-axis. The actual distance moved is $RelativeMovementX / ResolutionX$ millimeters. If the *ResolutionX* field of the [EFI_SIMPLE_POINTER_MODE](#) structure is 0, then this pointer device does not support an x-axis, and this field must be ignored.

RelativeMovementY The signed distance in counts that the pointer device has been moved along the y-axis. The actual distance moved is $RelativeMovementY / ResolutionY$ millimeters. If the *ResolutionY* field of the [EFI_SIMPLE_POINTER_MODE](#) structure is 0, then this pointer device does not support a y-axis, and this field must be ignored.

- RelativeMovementZ* The signed distance in counts that the pointer device has been moved along the z-axis. The actual distance moved is $RelativeMovementZ / ResolutionZ$ millimeters. If the *ResolutionZ* field of the **EFI_SIMPLE_POINTER_MODE** structure is 0, then this pointer device does not support a z-axis, and this field must be ignored.
- LeftButton* If **TRUE**, then the left button of the pointer device is being pressed. If **FALSE**, then the left button of the pointer device is not being pressed. If the *LeftButton* field of the **EFI_SIMPLE_POINTER_MODE** structure is **FALSE**, then this field is not valid, and must be ignored.
- RightButton* If **TRUE**, then the right button of the pointer device is being pressed. If **FALSE**, then the right button of the pointer device is not being pressed. If the *RightButton* field of the **EFI_SIMPLE_POINTER_MODE** structure is **FALSE**, then this field is not valid, and must be ignored.

Description

The **GetState()** function retrieves the current state of a pointer device. This includes information on the buttons associated with the pointer device and the distance that each of the axes associated with the pointer device has been moved. If the state of the pointer device has not changed since the last call to **GetState()**, then **EFI_NOT_READY** is returned. If the state of the pointer device has changed since the last call to **GetState()**, then the state information is placed in *State*, and **EFI_SUCCESS** is returned. If a device error occurs while attempting to retrieve the state information, then **EFI_DEVICE_ERROR** is returned.

Status Codes Returned

EFI_SUCCESS	The state of the pointer device was returned in <i>State</i> .
EFI_NOT_READY	The state of the pointer device has not changed since the last call to GetState() .
EFI_DEVICE_ERROR	A device error occurred while attempting to retrieve the pointer device's current state.

11.6 EFI Simple Pointer Device Paths

An **EFI_SIMPLE_POINTER_PROTOCOL** must be installed on a handle for its services to be available to drivers and applications written to this specification. In addition to the **EFI_SIMPLE_POINTER_PROTOCOL**, an **EFI_DEVICE_PATH_PROTOCOL** must also be installed on the same handle. See [Section 9.2](#) for a detailed description of the **EFI_DEVICE_PATH_PROTOCOL**.

A device path describes the location of a hardware component in a system from the processor's point of view. This includes the list of busses that lie between the processor and the pointer controller. The *UEFI Specification* takes advantage of the *ACPI Specification* to name system components. The following set of examples shows sample device paths for a PS/2* mouse, a serial mouse, and a USB mouse.

[Table 103](#) shows an example device path for a PS/2 mouse that is located behind a PCI to ISA bridge that is located at PCI device number 0x07 and PCI function 0x00, and is directly attached to a PCI root bridge. This device path consists of an ACPI Device Path Node for the PCI Root Bridge, a PCI Device Path Node for the PCI to ISA bridge, an ACPI Device Path Node for the PS/2 mouse, and a Device Path End Structure. The `_HID` and `_UID` of the first ACPI Device Path Node must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

ACPI (PNP0A03, 0) / PCI (7, 0) / ACPI (PNP0F03, 0)

Table 103. PS/2 Mouse Device Path

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	<code>_HID</code> PNP0A03 – 0x41D0 represents a compressed string ‘PNP’ and is in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	<code>_UID</code>
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x00	PCI Function
0x11	0x01	0x07	PCI Device
0x12	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x13	0x01	0x01	Sub type – ACPI Device Path
0x14	0x02	0x0C	Length – 0x0C bytes
0x16	0x04	0x41D0, 0x0F03	<code>_HID</code> PNP0A03 – 0x41D0 represents a compressed string ‘PNP’ and is in the low order bytes. The compression method is described in the ACPI Specification.
0x1A	0x04	0x0000	<code>_UID</code>
0x1E	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x1F	0x01	0xFF	Sub type – End of Entire Device Path
0x20	0x02	0x04	Length – 0x04 bytes

[Table 104](#) shows an example device path for a serial mouse that is located on COM 1 behind a PCI to ISA bridge that is located at PCI device number 0x07 and PCI function 0x00. The PCI to ISA bridge is directly attached to a PCI root bridge, and the communications parameters for COM 1 are 1200 baud, no parity, 8 data bits, and 1 stop bit. This device path consists of an ACPI Device Path Node for the PCI Root Bridge, a PCI Device Path Node for the PCI to ISA bridge, an ACPI Device Path Node for COM 1, a UART Device Path Node for the communications parameters, an ACPI Device Path Node for the serial mouse, and a Device Path End Structure. The `_HID` and `_UID` of the first ACPI Device Path Node must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

**ACPI (PNP0A03, 0) / PCI (7, 0) / ACPI (PNP0501, 0) / UART (1200, N, 8, 1) /
ACPI (PNP0F01, 0)**

Table 104. Serial Mouse Device Path

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path

0x3F	0x02	0x04	Length – 0x04 bytes
------	------	------	---------------------

Table 105 shows an example device path for a USB mouse that is behind a PCI to USB host controller that is located at PCI device number 0x07 and PCI function 0x02. The PCI to USB host controller is directly attached to a PCI root bridge. This device path consists of an ACPI Device Path Node for the PCI Root Bridge, a PCI Device Path Node for the PCI to USB controller, a USB Device Path Node, and a Device Path End Structure. The `_HID` and `_UID` of the first ACPI Device Path Node must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

ACPI (PNP0A03, 0) / PCI (7, 2) / USB (0, 0)

Table 105. USB Mouse Device Path

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	<code>_HID</code> PNP0A03 – 0x41D0 represents a compressed string ‘PNP’ and is in the low order bytes.
0x08	0x04	0x0000	<code>_UID</code>
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x02	PCI Function
0x11	0x01	0x07	PCI Device
0x12	0x01	0x03	Generic Device Path Header – Type Messaging Device Path
0x13	0x01	0x05	Sub type – USB
0x14	0x02	0x06	Length – 0x06 bytes
0x16	0x01	0x00	USB Port Number
0x17	0x01	0x00	USB Endpoint Number
0x18	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x19	0x01	0xFF	Sub type – End of Entire Device Path
0x1A	0x02	0x04	Length – 0x04 bytes

11.7 Absolute Pointer Protocol

This section defines the Absolute Pointer Protocol and a detailed description of the **EFI_ABSOLUTE_POINTER_PROTOCOL**. The intent of this section is to specify a simple method for accessing absolute pointer devices. This would include devices like touch screens, and digitizers. The **EFI_ABSOLUTE_POINTER_PROTOCOL** allows information about a pointer device to be

retrieved. This would include the status of buttons and the coordinates of the pointer device on the last time it was activated. This protocol is attached to the device handle of an absolute pointer device, and can be used for input from the user in the preboot environment.

Supported devices may return 1, 2, or 3 axis of information. The Z axis may optionally be used to return pressure data measurements derived from user pen force.

All supported devices must support a touch-active status. Supported devices may optionally support a second input button, for example a pen side-button.

EFI_ABSOLUTE_POINTER_PROTOCOL

Summary

Provides services that allow information about an absolute pointer device to be retrieved.

GUID

```
#define EFI_ABSOLUTE_POINTER_PROTOCOL_GUID \
    {0x8D59D32B, 0xC655, 0x4AE9, \
     {0x9B, 0x15, 0xF2, 0x59, 0x04, 0x99, 0x2A, 0x43}}
```

Protocol Interface Structure

```
typedef struct _EFI_ABSOLUTE_POINTER_PROTOCOL {
    EFI_ABSOLUTE_POINTER_RESET           Reset;
    EFI_ABSOLUTE_POINTER_GET_STATE       GetState;
    EFI_EVENT                             WaitForInput;
    EFI_ABSOLUTE_POINTER_MODE            *Mode;
} EFI_ABSOLUTE_POINTER_PROTOCOL;
```

Parameters

<i>Reset</i>	Resets the pointer device. See the Reset() function description.
<i>GetState</i>	Retrieves the current state of the pointer device. See the GetState() function description.
<i>WaitForInput</i>	Event to use with WaitForEvent() to wait for input from the pointer device.
<i>*Mode</i>	Pointer to EFI_ABSOLUTE_POINTER_MODE data. The type EFI_ABSOLUTE_POINTER_MODE is defined in "Related Definitions" below.

Related Definitions

```

//*****
// EFI_ABSOLUTE_POINTER_MODE
//*****
typedef struct {
    UINT64 AbsoluteMinX;
    UINT64 AbsoluteMinY;
    UINT64 AbsoluteMinZ;
    UINT64 AbsoluteMaxX;
    UINT64 AbsoluteMaxY;
    UINT64 AbsoluteMaxZ;
    UINT32 Attributes;
} EFI_ABSOLUTE_POINTER_MODE;
    
```

The following data values in the **EFI_ABSOLUTE_POINTER_MODE** interface are read-only and are changed by using the appropriate interface functions:

<i>AbsoluteMinX</i>	The Absolute Minimum of the device on the x-axis
<i>AbsoluteMinY</i>	The Absolute Minimum of the device on the y -axis.
<i>AbsoluteMinZ</i>	The Absolute Minimum of the device on the z-axis.
<i>AbsoluteMaxX</i>	The Absolute Maximum of the device on the x-axis. If 0, and the AbsoluteMinX is 0, then the pointer device does not support a x-axis.
<i>AbsoluteMaxY</i>	The Absolute Maximum of the device on the y -axis. If 0, and the AbsoluteMinX is 0, then the pointer device does not support a y-axis.
<i>AbsoluteMaxZ</i>	The Absolute Maximum of the device on the z-axis. If 0, and the AbsoluteMinX is 0, then the pointer device does not support a z-axis.
<i>Attributes</i>	The following bits are set as needed (or'd together) to indicate the capabilities of the device supported. The remaining bits are undefined and should be returned as 0.

```

#define EFI_ABSP_SupportsAltActive    0x00000001
#define EFI_ABSP_SupportsPressureAsZ 0x00000002
    
```

EFI_ABSP_SupportsAltActive	If set, indicates this device supports an alternate button input.
EFI_ABSP_SupportsPressureAsZ	If set, indicates this device returns pressure data in parameter CurrentZ.

The driver is not permitted to return all zeros for all three pairs of Min and Max as this would indicate no axis supported.

Description

The **EFI_ABSOLUTE_POINTER_PROTOCOL** provides a set of services for a pointer device that can be used as an input device from an application written to this specification. The services include the ability to reset the pointer device, retrieve the state of the pointer device, and retrieve the capabilities of the pointer device. In addition certain data items describing the device are provided.

EFI_ABSOLUTE_POINTER_PROTOCOL.Reset()

Summary

Resets the pointer device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ABSOLUTE_POINTER_RESET) (
    IN EFI_ABSOLUTE_POINTER_PROTOCOL *This,
    IN BOOLEAN ExtendedVerification
);
```

Parameters

- This* A pointer to the **EFI_ABSOLUTE_POINTER_PROTOCOL** instance. Type **EFI_ABSOLUTE_POINTER_PROTOCOL** is defined in this section.
- ExtendedVerification* Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

This Reset() function resets the pointer device hardware. As part of initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the ExtendedVerification flag is TRUE the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Codes Returned

EFI_SUCCESS	The device was reset.
EFI_DEVICE_ERROR	The device is not functioning correctly and could not be reset.

EFI_ABSOLUTE_POINTER_PROTOCOL.GetState()

Summary

Retrieves the current state of a pointer device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ABSOLUTE_POINTER_GET_STATE) (
    IN EFI_ABSOLUTE_POINTER_PROTOCOL    *This,
    IN OUT EFI_ABSOLUTE_POINTER_STATE  *State
);
```

Parameters

<i>This</i>	A pointer to the EFI_ABSOLUTE_POINTER_PROTOCOL instance. Type EFI_ABSOLUTE_POINTER_PROTOCOL is defined in Section 11.7 .
<i>State</i>	A pointer to the state information on the pointer device. Type EFI_ABSOLUTE_POINTER_STATE is defined in "Related Definitions" below.

Related Definitions

```

//*****
// EFI_ABSOLUTE_POINTER_STATE
//*****
typedef struct {
    UINT64 CurrentX;
    UINT64 CurrentY;
    UINT64 CurrentZ;
    UINT32 ActiveButtons;
} EFI_ABSOLUTE_POINTER_STATE;
```

<i>CurrentX</i>	The unsigned position of the activation on the x axis If the AbsoluteMinX and the AbsoluteMaxX fields of the EFI_ABSOLUTE_POINTER_MODE structure are both 0, then this pointer device does not support an x-axis, and this field must be ignored.
-----------------	--

<i>CurrentY</i>	The unsigned position of the activation on the y axis If the AbsoluteMinY and the AbsoluteMaxY fields of the EFI_ABSOLUTE_POINTER_MODE structure are both 0, then this pointer device does not support a y-axis, and this field must be ignored.
-----------------	---

<i>CurrentZ</i>	The unsigned position of the activation on the z axis, or the pressure measurement. If the AbsoluteMinZ and the AbsoluteMaxZ fields of the EFI_ABSOLUTE_POINTER_MODE structure are
-----------------	---

both 0, then this pointer device does not support a z-axis, and this field must be ignored.

ActiveButtons

Bits are set to 1 in this structure item to indicate that device buttons are active.

Related Definitions

```

//*****
//definitions of bits within ActiveButtons
//*****
#define EFI_Absp_TouchActive    0x00000001
#define EFI_ABS_AltActive      0x00000002
    
```

EFI_Absp_TouchActive This bit is set if the touch sensor is active

EFI_ABS_AltActive This bit is set if the alt sensor, such as pen-side button, is active.

Description

The `GetState()` function retrieves the current state of a pointer device. This includes information on the active state associated with the pointer device and the current position of the axes associated with the pointer device. If the state of the pointer device has not changed since the last call to `GetState()`, then **EFI_NOT_READY** is returned. If the state of the pointer device has changed since the last call to `GetState()`, then the state information is placed in `State`, and **EFI_SUCCESS** is returned. If a device error occurs while attempting to retrieve the state information, then **EFI_DEVICE_ERROR** is returned.

Status Codes Returned

EFI_SUCCESS	The state of the pointer device was returned in <i>State</i> .
EFI_NOT_READY	The state of the pointer device has not changed since the last call to GetState() .
EFI_DEVICE_ERROR	A device error occurred while attempting to retrieve the pointer device's current state.

11.8 Serial I/O Protocol

This section defines the Serial I/O protocol. This protocol is used to abstract byte stream devices.

EFI_SERIAL_IO_PROTOCOL

Summary

This protocol is used to communicate with any type of character-based I/O device.

GUID

```
#define EFI_SERIAL_IO_PROTOCOL_GUID \
    { 0xBB25CF6F, 0xF1D4, 0x11D2, \
      0x9a, 0x0c, 0x00, 0x90, 0x27, 0x3f, 0xc1, 0xfd }
```

Revision Number

```
#define EFI_SERIAL_IO_PROTOCOL_REVISION    0x00010000
```

Protocol Interface Structure

```
typedef struct {
    UINT32                Revision;
    EFI_SERIAL_RESET      Reset;
    EFI_SERIAL_SET_ATTRIBUTES SetAttributes;
    EFI_SERIAL_SET_CONTROL_BITS SetControl;
    EFI_SERIAL_GET_CONTROL_BITS GetControl;
    EFI_SERIAL_WRITE      Write;
    EFI_SERIAL_READ       Read;
    SERIAL_IO_MODE        *Mode;
} EFI_SERIAL_IO_PROTOCOL;
```

Parameters

<i>Revision</i>	The revision to which the EFI_SERIAL_IO_PROTOCOL adheres. All future revisions must be backwards compatible. If a future version is not backwards compatible, it is not the same GUID.
<i>Reset</i>	Resets the hardware device.
<i>SetAttributes</i>	Sets communication parameters for a serial device. These include the baud rate, receive FIFO depth, transmit/receive time out, parity, data bits, and stop bit attributes.
<i>SetControl</i>	Sets the control bits on a serial device. These include Request to Send and Data Terminal Ready.
<i>GetControl</i>	Reads the status of the control bits on a serial device. These include Clear to Send, Data Set Ready, Ring Indicator, and Carrier Detect.
<i>Write</i>	Sends a buffer of characters to a serial device.
<i>Read</i>	Receives a buffer of characters from a serial device.
<i>Mode</i>	Pointer to SERIAL_IO_MODE data. Type SERIAL_IO_MODE is defined in “Related Definitions” below.

Related Definitions

```

//*****
// SERIAL_IO_MODE
//*****
typedef struct {
    UINT32          ControlMask;

    // current Attributes
    UINT32          Timeout;
    UINT64          BaudRate;
    UINT32          ReceiveFifoDepth;
    UINT32          DataBits;
    UINT32          Parity;
    UINT32          StopBits;
} SERIAL_IO_MODE;

```

The data values in the **SERIAL_IO_MODE** are read-only and are updated by the code that produces the **EFI_SERIAL_IO_PROTOCOL** functions:

<i>ControlMask</i>	A mask of the Control bits that the device supports. The device must always support the Input Buffer Empty control bit.
<i>Timeout</i>	If applicable, the number of microseconds to wait before timing out a Read or Write operation.
<i>BaudRate</i>	If applicable, the current baud rate setting of the device; otherwise, baud rate has the value of zero to indicate that device runs at the device's designed speed.
<i>ReceiveFifoDepth</i>	The number of characters the device will buffer on input.
<i>DataBits</i>	The number of data bits in each character.
<i>Parity</i>	If applicable, this is the EFI_PARITY_TYPE that is computed or checked as each character is transmitted or received. If the device does not support parity the value is the default parity value.
<i>StopBits</i>	If applicable, the EFI_STOP_BITS_TYPE number of stop bits per character. If the device does not support stop bits the value is the default stop bit value.

```

//*****
// EFI_PARITY_TYPE
//*****
typedef enum {
    DefaultParity,
    NoParity,
    EvenParity,
    OddParity,
    MarkParity,
    SpaceParity
} EFI_PARITY_TYPE;

//*****
// EFI_STOP_BITS_TYPE
//*****
typedef enum {
    DefaultStopBits,
    OneStopBit,          // 1 stop bit
    OneFiveStopBits,    // 1.5 stop bits
    TwoStopBits         // 2 stop bits
} EFI_STOP_BITS_TYPE;

```

Description

The Serial I/O protocol is used to communicate with UART-style serial devices. These can be standard UART serial ports in PC-AT systems, serial ports attached to a USB interface, or potentially any character-based I/O device.

The Serial I/O protocol can control byte I/O style devices from a generic device, to a device with features such as a UART. As such many of the serial I/O features are optional to allow for the case of devices that do not have UART controls. Each of these options is called out in the specific serial I/O functions.

The default attributes for all UART-style serial device interfaces are: 115,200 baud, a 1 byte receive FIFO, a 1,000,000 microsecond timeout per character, no parity, 8 data bits, and 1 stop bit. Flow control is the responsibility of the software that uses the protocol. Hardware flow control can be implemented through the use of the [GetControl \(\)](#) and [SetControl \(\)](#) functions (described below) to monitor and assert the flow control signals. The XON/XOFF flow control algorithm can be implemented in software by inserting XON and XOFF characters into the serial data stream as required.

Special care must be taken if a significant amount of data is going to be read from a serial device. Since UEFI drivers are polled mode drivers, characters received on a serial device might be missed. It is the responsibility of the software that uses the protocol to check for new data often enough to guarantee that no characters will be missed. The required polling frequency depends on the baud rate of the connection and the depth of the receive FIFO.

EFI_SERIAL_IO_PROTOCOL.Reset()

Summary

Resets the serial device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERIAL_RESET) (
    IN EFI_SERIAL_IO_PROTOCOL *This
);
```

Parameters

This A pointer to the **EFI_SERIAL_IO_PROTOCOL** instance.
Type **EFI_SERIAL_IO_PROTOCOL** is defined in [Section 11.8](#).

Description

The **Reset()** function resets the hardware of a serial device.

Status Codes Returned

EFI_SUCCESS	The serial device was reset.
EFI_DEVICE_ERROR	The serial device could not be reset.

EFI_SERIAL_IO_PROTOCOL.SetAttributes()

Summary

Sets the baud rate, receive FIFO depth, transmit/receive time out, parity, data bits, and stop bits on a serial device.

```

EFI_STATUS
(EFIAPI *EFI_SERIAL_SET_ATTRIBUTES) (
    IN EFI_SERIAL_IO_PROTOCOL  *This,
    IN UINT64                   BaudRate,
    IN UINT32                   ReceiveFifoDepth,
    IN UINT32                   Timeout
    IN EFI_PARITY_TYPE          Parity,
    IN UINT8                    DataBits,
    IN EFI_STOP_BITS_TYPE       StopBits
);
    
```

Parameters

<i>This</i>	A pointer to the EFI_SERIAL_IO_PROTOCOL instance. Type EFI_SERIAL_IO_PROTOCOL is defined in Section 11.8 .
<i>BaudRate</i>	The requested baud rate. A <i>BaudRate</i> value of 0 will use the device's default interface speed.
<i>ReceiveFifoDepth</i>	The requested depth of the FIFO on the receive side of the serial interface. A <i>ReceiveFifoDepth</i> value of 0 will use the device's default FIFO depth.
<i>Timeout</i>	The requested time out for a single character in microseconds. This timeout applies to both the transmit and receive side of the interface. A <i>Timeout</i> value of 0 will use the device's default time out value.
<i>Parity</i>	The type of parity to use on this serial device. A <i>Parity</i> value of DefaultParity will use the device's default parity value. Type EFI_PARITY_TYPE is defined in "Related Definitions" in Section 11.8 .
<i>DataBits</i>	The number of data bits to use on this serial device. A <i>DataBits</i> value of 0 will use the device's default data bit setting.
<i>StopBits</i>	The number of stop bits to use on this serial device. A <i>StopBits</i> value of DefaultStopBits will use the device's default number of stop bits. Type EFI_STOP_BITS_TYPE is defined in "Related Definitions" in Section 11.8 .

Description

The **SetAttributes()** function sets the baud rate, receive-FIFO depth, transmit/receive time out, parity, data bits, and stop bits on a serial device.

Unified Extensible Firmware Interface Specification

The controller for a serial device is programmed with the specified attributes. If the *Parity*, *DataBits*, or *StopBits* values are not valid, then an error will be returned. If the specified *BaudRate* is below the minimum baud rate supported by the serial device, an error will be returned. The nearest baud rate supported by the serial device will be selected without exceeding the *BaudRate* parameter. If the specified *ReceiveFifoDepth* is below the smallest FIFO size supported by the serial device, an error will be returned. The nearest FIFO size supported by the serial device will be selected without exceeding the *ReceiveFifoDepth* parameter.

Status Codes Returned

EFI_SUCCESS	The new attributes were set on the serial device.
EFI_INVALID_PARAMETER	One or more of the attributes has an unsupported value.
EFI_DEVICE_ERROR	The serial device is not functioning correctly.

EFI_SERIAL_IO_PROTOCOL.SetControl()

Summary

Sets the control bits on a serial device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERIAL_SET_CONTROL_BITS) (
    IN EFI_SERIAL_IO_PROTOCOL  *This,
    IN UINT32                    Control
);
```

Parameters

<i>This</i>	A pointer to the EFI_SERIAL_IO_PROTOCOL instance. Type EFI_SERIAL_IO_PROTOCOL is defined in Section 11.8 .
<i>Control</i>	Sets the bits of <i>Control</i> that are settable. See “Related Definitions” below.

Related Definitions

```

//*****
// CONTROL BITS
//*****

#define EFI_SERIAL_CLEAR_TO_SEND           0x0010
#define EFI_SERIAL_DATA_SET_READY         0x0020
#define EFI_SERIAL_RING_INDICATE          0x0040
#define EFI_SERIAL_CARRIER_DETECT        0x0080
#define EFI_SERIAL_REQUEST_TO_SEND        0x0002
#define EFI_SERIAL_DATA_TERMINAL_READY    0x0001

#define EFI_SERIAL_HARDWARE_LOOPBACK_ENABLE 0x1000
#define EFI_SERIAL_SOFTWARE_LOOPBACK_ENABLE 0x2000
#define EFI_SERIAL_HARDWARE_FLOW_CONTROL_ENABLE 0x4000

```

Description

The **SetControl()** function is used to assert or deassert the control signals on a serial device. The following signals are set according their bit settings:

- Request to Send
- Data Terminal Ready

Only the **REQUEST_TO_SEND**, **DATA_TERMINAL_READY**, **HARDWARE_LOOPBACK_ENABLE**, **SOFTWARE_LOOPBACK_ENABLE**, and **HARDWARE_FLOW_CONTROL_ENABLE** bits can be set with **SetControl()**. All the bits can be read with [GetControl\(\)](#).

Status Codes Returned

EFI_SUCCESS	The new control bits were set on the serial device.
EFI_UNSUPPORTED	The serial device does not support this operation.
EFI_DEVICE_ERROR	The serial device is not functioning correctly.

EFI_SERIAL_IO_PROTOCOL.GetControl()

Summary

Retrieves the status of the control bits on a serial device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERIAL_GET_CONTROL_BITS) (
    IN EFI_SERIAL_IO_PROTOCOL  *This,
    OUT UINT32                  *Control
);
```

Parameters

This A pointer to the **EFI_SERIAL_IO_PROTOCOL** instance. Type **EFI_SERIAL_IO_PROTOCOL** is defined in [Section 11.8](#).

Control A pointer to return the current control signals from the serial device. See “Related Definitions” below.

Related Definitions

```

//*****
// CONTROL BITS

#define EFI_SERIAL_OUTPUT_BUFFER_EMPTY    0x0200
#define EFI_SERIAL_HARDWARE_LOOPBACK_ENABLE 0x1000
#define EFI_SERIAL_SOFTWARE_LOOPBACK_ENABLE 0x2000
#define EFI_SERIAL_HARDWARE_FLOW_CONTROL_ENABLE 0x4000

```

Description

The **GetControl()** function retrieves the status of the control bits on a serial device.

Status Codes Returned

EFI_SUCCESS	The control bits were read from the serial device.
EFI_DEVICE_ERROR	The serial device is not functioning correctly.

EFI_SERIAL_IO_PROTOCOL.Write()

Summary

Writes data to a serial device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERIAL_WRITE) (
    IN EFI_SERIAL_IO_PROTOCOL  *This,
    IN OUT UINTN                *BufferSize,
    IN VOID                     *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_SERIAL_IO_PROTOCOL instance. Type EFI_SERIAL_IO_PROTOCOL is defined in Section 11.8 .
<i>BufferSize</i>	On input, the size of the <i>Buffer</i> . On output, the amount of data actually written.
<i>Buffer</i>	The buffer of data to write.

Description

The **Write()** function writes the specified number of bytes to a serial device. If a time out error occurs while data is being sent to the serial port, transmission of this buffer will terminate, and **EFI_TIMEOUT** will be returned. In all cases the number of bytes actually written to the serial device is returned in *BufferSize*.

Status Codes Returned

EFI_SUCCESS	The data was written.
EFI_DEVICE_ERROR	The device reported an error.
EFI_TIMEOUT	The data write was stopped due to a timeout.

EFI_SERIAL_IO_PROTOCOL.Read()

Summary

Reads data from a serial device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERIAL_READ) (
    IN EFI_SERIAL_IO_PROTOCOL *This,
    IN OUT UINTN *BufferSize,
    OUT VOID *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_SERIAL_IO_PROTOCOL instance. Type EFI_SERIAL_IO_PROTOCOL is defined in Section 11.8 .
<i>BufferSize</i>	On input, the size of the <i>Buffer</i> . On output, the amount of data returned in <i>Buffer</i> .
<i>Buffer</i>	The buffer to return the data into.

Description

The **Read()** function reads a specified number of bytes from a serial device. If a time out error or an overrun error is detected while data is being read from the serial device, then no more characters will be read, and an error will be returned. In all cases the number of bytes actually read is returned in *BufferSize*.

Status Codes Returned

EFI_SUCCESS	The data was read.
EFI_DEVICE_ERROR	The serial device reported an error.
EFI_TIMEOUT	The operation was stopped due to a timeout or overrun.

11.9 Graphics Output Protocol

The goal of this section is to replace the functionality that currently exists with VGA hardware and its corresponding video BIOS. The Graphics Output Protocol is a software abstraction and its goal is to support any foreseeable graphics hardware and not require VGA hardware, while at the same time also lending itself to implementation on the current generation of VGA hardware.

Graphics output is important in the pre-boot space to support modern firmware features. These features include the display of logos, the localization of output to any language, and setup and configuration screens.

Graphics output may also be required as part of the startup of an operating system. There are potentially times in modern operating systems prior to the loading of a high performance OS graphics driver where access to graphics output device is required. The Graphics Output Protocol

supports this capability by providing the EFI OS loader access to a hardware frame buffer and enough information to allow the OS to draw directly to the graphics output device.

The [EFI GRAPHICS OUTPUT PROTOCOL](#) supports three member functions to support the limited graphics needs of the pre-boot environment. These member functions allow the caller to draw to a virtualized frame buffer, retrieve the supported video modes, and to set a video mode. These simple primitives are sufficient to support the general needs of pre-OS firmware code.

The [EFI_GRAPHICS_OUTPUT_PROTOCOL](#) also exports enough information about the current mode for operating system startup software to access the linear frame buffer directly.

The interface structure for the Graphics Output protocol is defined in this section. A unique Graphics Output protocol must represent each video frame buffer in the system that is driven out to one or more video output devices.

11.9.1 Blt Buffer

The basic graphics operation in the [EFI_GRAPHICS_OUTPUT_PROTOCOL](#) is the Block Transfer or Blt. The Blt operation allows data to be read or written to the video adapter's video memory. The Blt operation abstracts the video adapters hardware implementation by introducing the concept of a software Blt buffer.

The frame buffer abstracts the video display as an array of pixels. Each pixels location on the video display is defined by its X and Y coordinates. The X coordinate represents a scan line. A scan line is a horizontal line of pixels on the display. The Y coordinate represents a vertical line on the display. The upper left hand corner of the video display is defined as (0, 0) where the notation (X, Y) represents the X and Y coordinate of the pixel. The lower right corner of the video display is represented by (Width - 1, Height - 1).

The software Blt buffer is structured as an array of pixels. Pixel (0, 0) is the first element of the software Blt buffer. The Blt buffer can be thought of as a set of scan lines. It is possible to convert a pixel location on the video display to the Blt buffer using the following algorithm: Blt buffer array index = Y * Width + X.

Each software Blt buffer entry represents a pixel that is comprised of a 32-bit quantity. Byte zero of the Blt buffer entry represents the Red component of the pixel. Byte one of the Blt buffer entry represents the Green component of the pixel. Byte two of the Blt buffer entry represents the Blue component of the pixel. Byte three of the Blt buffer entry is reserved and must be zero. The byte values for the red, green, and blue components represent the color intensity. This color intensity value range from a minimum intensity of 0 to maximum intensity of 255.

OM13157

Figure 29. Software BLT Buffer

EFI_GRAPHICS_OUTPUT_PROTOCOL

Summary

Provides a basic abstraction to set video modes and copy pixels to and from the graphics controller's frame buffer. The linear address of the hardware frame buffer is also exposed so software can write directly to the video hardware.

GUID

```
#define EFI_GRAPHICS_OUTPUT_PROTOCOL_GUID \
    {0x9042a9de, 0x23dc, 0x4a38, \
     {0x96, 0xfb, 0x7a, 0xde, 0xd0, 0x80, 0x51, 0x6a}}
```

Protocol Interface Structure

```
typedef struct EFI_GRAPHICS_OUTPUT_PROTOCOL {
    EFI_GRAPHICS_OUTPUT_PROTOCOL_QUERY_MODE QueryMode;
    EFI_GRAPHICS_OUTPUT_PROTOCOL_SET_MODE SetMode;
    EFI_GRAPHICS_OUTPUT_PROTOCOL_BLT Blt;
    EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE *Mode;
} EFI_GRAPHICS_OUTPUT_PROTOCOL;
```

Parameters

QueryMode

Returns information for an available graphics mode that the graphics device and the set of active video output devices supports.

<i>SetMode</i>	Set the video device into the specified mode and clears the visible portions of the output display to black.
<i>Blt</i>	Software abstraction to draw on the video device's frame buffer.
<i>Mode</i>	Pointer to EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE data. Type EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE is defined in "Related Definitions" below.

Related Definitions

```
typedef struct {
    UINT32      RedMask;
    UINT32      GreenMask;
    UINT32      BlueMask;
    UINT32      ReservedMask;
} EFI_PIXEL_BITMASK;
```

If a bit is set in *RedMask*, *GreenMask*, or *BlueMask* then those bits of the pixel represent the corresponding color. Bits in *RedMask*, *GreenMask*, *BlueMask*, and *ReservedMask* must not overlap bit positions. The values for the red, green, and blue components in the bit mask represent the color intensity. The color intensities must increase as the color values for a each color mask increase with a minimum intensity of all bits in a color mask clear to a maximum intensity of all bits in a color mask set.

```
typedef enum {
    PixelRedGreenBlueReserved8BitPerColor,
    PixelBlueGreenRedReserved8BitPerColor,
    PixelBitMask,
    PixelBltOnly,
    PixelFormatMax
} EFI_GRAPHICS_PIXEL_FORMAT;
```

PixelRedGreenBlueReserved8BitPerColor

A pixel is 32-bits and byte zero represents red, byte one represents green, byte two represents blue, and byte three is reserved. This is the definition for the physical frame buffer. The byte values for the red, green, and blue components represent the color intensity. This color intensity value range from a minimum intensity of 0 to maximum intensity of 255.

PixelBlueGreenRedReserved8BitPerColor

A pixel is 32-bits and byte zero represents blue, byte one represents green, byte two represents red, and byte three is reserved. This is the definition for the physical frame buffer. The byte values for the red, green, and blue components represent the color intensity. This color intensity value range from a minimum intensity of 0 to maximum intensity of 255.

PixelBitMask

The pixel definition of the physical frame buffer is defined by **EFI_PIXEL_BITMASK**.

PixelBltOnly

This mode does not support a physical frame buffer.

PixelFormatMax Valid **EFI_GRAPHICS_PIXEL_FORMAT** enum values are less than this value.

```
typedef struct {
    UINT32          Version;
    UINT32          HorizontalResolution;
    UINT32          VerticalResolution;
    EFI_GRAPHICS_PIXEL_FORMAT PixelFormat;
    EFI_PIXEL_BITMASK PixelInformation;
    UINT32          PixelsPerScanLine;
} EFI_GRAPHICS_OUTPUT_MODE_INFORMATION;
```

Version The version of this data structure. A value of zero represents the **EFI_GRAPHICS_OUTPUT_MODE_INFORMATION** structure as defined in this specification. Future version of this specification may extend this data structure in a backwards compatible way and increase the value of *Version*.

HorizontalResolution The size of video screen in pixels in the X dimension.

VerticalResolution The size of video screen in pixels in the Y dimension.

PixelFormat Enumeration that defines the physical format of the pixel. A value of *PixelFormatOnly* implies that a linear frame buffer is not available for this mode.

PixelInformation This bit-mask is only valid if *PixelFormat* is set to *PixelFormatBitMask*. A bit being set defines what bits are used for what purpose such as Red, Green, Blue, or Reserved.

PixelsPerScanLine Defines the number of pixel elements per video memory line. For performance reasons, or due to hardware restrictions, scan lines may be padded to an amount of memory alignment. These padding pixel elements are outside the area covered by *HorizontalResolution* and are not visible. For direct frame buffer access, this number is used as a span between starts of pixel lines in video memory. Based on the size of an individual pixel element and *PixelsPerScanline*, the offset in video memory from pixel element (x, y) to pixel element (x, y+1) has to be calculated as "sizeof(PixelElement) * PixelsPerScanLine", not "sizeof(PixelElement) * HorizontalResolution", though in many cases those values can coincide. This value can depend on video hardware and mode resolution. GOP implementation is responsible for providing accurate value for this field.

Note: The following code sample is an example of the intended field usage:

```

INTN
GetPixelElementSize (
    IN EFI_PIXEL_BITMASK *PixelBits
)
{
    INTN HighestPixel = -1;

    INTN BluePixel;
    INTN RedPixel;
    INTN GreenPixel;
    INTN RsvdPixel;

    BluePixel = FindHighestSetBit (PixelBits->BlueMask);
    RedPixel = FindHighestSetBit (PixelBits->RedMask);
    GreenPixel = FindHighestSetBit (PixelBits->GreenMask);
    RsvdPixel = FindHighestSetBit (PixelBits->ReservedMask);

    HighestPixel = max (BluePixel, RedPixel);
    HighestPixel = max (HighestPixel, GreenPixel);
    HighestPixel = max (HighestPixel, RsvdPixel);

    return HighestPixel;
}

EFI_PHYSICAL_ADDRESS          NewPixelAddress;
EFI_PHYSICAL_ADDRESS          CurrentPixelAddress;
EFI_GRAPHICS_OUTPUT_MODE_INFORMATION OutputInfo;
INTN                          PixelElementSize;

switch (OutputInfo.PixelFormat) {
    case PixelBitMask:
        PixelElementSize =
            GetPixelElementSize (&OutputInfo.PixelInformation);
        break;

    case PixelBlueGreenRedReserved8BitPerColor:
    case PixelRedGreenBlueReserved8BitPerColor:
        PixelElementSize =
            sizeof (EFI_GRAPHICS_OUTPUT_BLT_PIXEL);
        break;
}

//
// NewPixelAddress after execution points to the pixel
// positioned one line below the one pointed by

```

```
// CurrentPixelAddress
//
NewPixelAddress = CurrentPixelAddress +
                  (PixelElementSize *
                   OutputInfo.PixelsPerScanLine);
```

End of note code sample.

```
typedef struct {
    UINT32           MaxMode;
    UINT32           Mode;
    EFI_GRAPHICS_OUTPUT_MODE_INFORMATION *Info;
    UINTN           SizeOfInfo;
    EFI_PHYSICAL_ADDRESS FrameBufferBase;
    UINTN           FrameBufferSize;
} EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE;
```

The **EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE** is read-only and values are only changed by using the appropriate interface functions:

<i>MaxMode</i>	The number of modes supported by QueryMode () and SetMode () .
<i>Mode</i>	Current Mode of the graphics device. Valid mode numbers are 0 to <i>MaxMode</i> -1.
<i>Info</i>	Pointer to read-only EFI_GRAPHICS_OUTPUT_MODE_INFORMATION data.
<i>SizeOfInfo</i>	Size of <i>Info</i> structure in bytes. Future versions of this specification may increase the size of the EFI_GRAPHICS_OUTPUT_MODE_INFORMATION data.
<i>FrameBufferBase</i>	Base address of graphics linear frame buffer. <i>Info</i> contains information required to allow software to draw directly to the frame buffer without using Blt () . Offset zero in <i>FrameBufferBase</i> represents the upper left pixel of the display.
<i>FrameBufferSize</i>	Amount of frame buffer needed to support the active mode as defined by <i>PixelsPerScanLine</i> x <i>VerticalResolution</i> x <i>PixelElementSize</i> .

Description

The **EFI_GRAPHICS_OUTPUT_PROTOCOL** provides a software abstraction to allow pixels to be drawn directly to the frame buffer. The **EFI_GRAPHICS_OUTPUT_PROTOCOL** is designed to be lightweight and to support the basic needs of graphics output prior to Operating System boot.

EFI_GRAPHICS_OUTPUT_PROTOCOL.QueryMode()

Summary

Returns information for an available graphics mode that the graphics device and the set of active video output devices supports.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_GRAPHICS_OUTPUT_PROTOCOL_QUERY_MODE) (
    IN  EFI_GRAPHICS_OUTPUT_PROTOCOL      *This,
    IN  UINT32                             ModeNumber,
    OUT UINTN                             *SizeOfInfo
    OUT EFI_GRAPHICS_OUTPUT_MODE_INFORMATION **Info
);
```

Parameters

<i>This</i>	The EFI_GRAPHICS_OUTPUT_PROTOCOL instance. Type EFI_GRAPHICS_OUTPUT_PROTOCOL is defined in this section.
<i>ModeNumber</i>	The mode number to return information on. The current mode and valid modes are read-only values in the <i>Mode</i> structure of the EFI_GRAPHICS_OUTPUT_PROTOCOL .
<i>SizeOfInfo</i>	A pointer to the size, in bytes, of the <i>Info</i> buffer.
<i>Info</i>	A pointer to a callee allocated buffer that returns information about <i>ModeNumber</i> .

Description

The **QueryMode()** function returns information for an available graphics mode that the graphics device and the set of active video output devices supports. If *ModeNumber* is not between 0 and *MaxMode* - 1, then [EFI_INVALID_PARAMETER](#) is returned. *MaxMode* is available from the *Mode* structure of the [EFI_GRAPHICS_OUTPUT_PROTOCOL](#).

The size of the *Info* structure should never be assumed and the value of *SizeOfInfo* is the only valid way to know the size of *Info*.

If the [EFI_GRAPHICS_OUTPUT_PROTOCOL](#) is installed on the handle that represents a single video output device, then the set of modes returned by this service is the subset of modes supported by both the graphics controller and the video output device.

If the [EFI_GRAPHICS_OUTPUT_PROTOCOL](#) is installed on the handle that represents a combination of video output devices, then the set of modes returned by this service is the subset of modes supported by the graphics controller and the all of the video output devices represented by the handle.

Status Codes Returned

EFI_SUCCESS	Valid mode information was returned.
-------------	--------------------------------------

EFI_DEVICE_ERROR	A hardware error occurred trying to retrieve the video mode.
EFI_INVALID_PARAMETER	<i>ModeNumber</i> is not valid.

EFI_GRAPHICS_OUTPUT_PROTOCOL.SetMode()

Summary

Set the video device into the specified mode and clears the visible portions of the output display to black.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_GRAPHICS_OUTPUT_PROTOCOL_SET_MODE) (
    IN EFI_GRAPHICS_OUTPUT_PROTOCOL *This,
    IN UINT32 ModeNumber
);
```

Parameters

<i>This</i>	The EFI_GRAPHICS_OUTPUT_PROTOCOL instance. Type EFI_GRAPHICS_OUTPUT_PROTOCOL is defined in this section.
<i>ModeNumber</i>	Abstraction that defines the current video mode. The current mode and valid modes are read-only values in the <i>Mode</i> structure of the EFI_GRAPHICS_OUTPUT_PROTOCOL .

Description

This **SetMode ()** function sets the graphics device and the set of active video output devices to the video mode specified by *ModeNumber*. If *ModeNumber* is not supported **EFI_UNSUPPORTED** is returned.

If a device error occurs while attempting to set the video mode, then **EFI_DEVICE_ERROR** is returned. Otherwise, the graphics device is set to the requested geometry, the set of active output devices are set to the requested geometry, the visible portion of the hardware frame buffer is cleared to black, and **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The graphics mode specified by <i>ModeNumber</i> was selected.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.
EFI_UNSUPPORTED	<i>ModeNumber</i> is not supported by this device.

EFI_GRAPHICS_OUTPUT_PROTOCOL.Blt()

Summary

Blt a rectangle of pixels on the graphics screen. Blt stands for BLock Transfer.

Prototype

```
typedef struct {
    UINT8    Blue;
    UINT8    Green;
    UINT8    Red;
    UINT8    Reserved;
} EFI_GRAPHICS_OUTPUT_BLT_PIXEL;

typedef enum {
    EfiBltVideoFill,
    EfiBltVideoToBltBuffer,
    EfiBltBufferToVideo,
    EfiBltVideoToVideo,
    EfiGraphicsOutputBltOperationMax
} EFI_GRAPHICS_OUTPUT_BLT_OPERATION;

typedef
EFI_STATUS
(EFI_API *EFI_GRAPHICS_OUTPUT_PROTOCOL_BLT) (
    IN EFI_GRAPHICS_OUTPUT_PROTOCOL          *This,
    IN OUT EFI_GRAPHICS_OUTPUT_BLT_PIXEL    *BltBuffer, OPTIONAL
    IN EFI_GRAPHICS_OUTPUT_BLT_OPERATION    BltOperation,
    IN UINTN                                 SourceX,
    IN UINTN                                 SourceY,
    IN UINTN                                 DestinationX,
    IN UINTN                                 DestinationY,
    IN UINTN                                 Width,
    IN UINTN                                 Height,
    IN UINTN                                 Delta      OPTIONAL
);
```

Parameters

<i>This</i>	The EFI_GRAPHICS_OUTPUT_PROTOCOL instance.
<i>BltBuffer</i>	The data to transfer to the graphics screen. Size is at least $Width * Height * \text{sizeof}(EFI_GRAPHICS_OUTPUT_BLT_PIXEL)$.
<i>BltOperation</i>	The operation to perform when copying <i>BltBuffer</i> on to the graphics screen.
<i>SourceX</i>	The X coordinate of the source for the <i>BltOperation</i> . The origin of the screen is 0, 0 and that is the upper left-hand corner of the screen.

<i>SourceY</i>	The Y coordinate of the source for the <i>BltOperation</i> . The origin of the screen is 0, 0 and that is the upper left-hand corner of the screen.
<i>DestinationX</i>	The X coordinate of the destination for the <i>BltOperation</i> . The origin of the screen is 0, 0 and that is the upper left-hand corner of the screen.
<i>DestinationY</i>	The Y coordinate of the destination for the <i>BltOperation</i> . The origin of the screen is 0, 0 and that is the upper left-hand corner of the screen.
<i>Width</i>	The width of a rectangle in the blt rectangle in pixels. Each pixel is represented by an EFI_GRAPHICS_OUTPUT_BLT_PIXEL element.
<i>Height</i>	The height of a rectangle in the blt rectangle in pixels. Each pixel is represented by an EFI_GRAPHICS_OUTPUT_BLT_PIXEL element.
<i>Delta</i>	Not used for <i>EfiBltVideoFill</i> or the <i>EfiBltVideoToVideo</i> operation. If a <i>Delta</i> of zero is used, the entire <i>BltBuffer</i> is being operated on. If a subrectangle of the <i>BltBuffer</i> is being used then <i>Delta</i> represents the number of bytes in a row of the <i>BltBuffer</i> .

Description

The **Blt()** function is used to draw the *BltBuffer* rectangle onto the video screen.

The *BltBuffer* represents a rectangle of *Height* by *Width* pixels that will be drawn on the graphics screen using the operation specified by *BltOperation*. The *Delta* value can be used to enable the *BltOperation* to be performed on a sub-rectangle of the *BltBuffer*.

[Table 106](#) describes the *BltOperations* that are supported on rectangles. Rectangles have coordinates (left, upper) (right, bottom):

Table 106. Blt Operation Table

Blt Operation	Operation
EfiBltVideoFill	Write data from the <i>BltBuffer</i> pixel (0,0) directly to every pixel of the video display rectangle (<i>DestinationX</i> , <i>DestinationY</i>) (<i>DestinationX</i> + <i>Width</i> , <i>DestinationY</i> + <i>Height</i>). Only one pixel will be used from the <i>BltBuffer</i> . <i>Delta</i> is NOT used.
EfiBltVideoToBltBuffer	Read data from the video display rectangle (<i>SourceX</i> , <i>SourceY</i>) (<i>SourceX</i> + <i>Width</i> , <i>SourceY</i> + <i>Height</i>) and place it in the <i>BltBuffer</i> rectangle (<i>DestinationX</i> , <i>DestinationY</i>) (<i>DestinationX</i> + <i>Width</i> , <i>DestinationY</i> + <i>Height</i>). If <i>DestinationX</i> or <i>DestinationY</i> is not zero then <i>Delta</i> must be set to the length in bytes of a row in the <i>BltBuffer</i> .

Blt Operation	Operation
EfiBltBufferToVideo	Write data from the <i>BltBuffer</i> rectangle (<i>SourceX</i> , <i>SourceY</i>) (<i>SourceX</i> + <i>Width</i> , <i>SourceY</i> + <i>Height</i>) directly to the video display rectangle (<i>DestinationX</i> , <i>DestinationY</i>) (<i>DestinationX</i> + <i>Width</i> , <i>DestinationY</i> + <i>Height</i>). If <i>SourceX</i> or <i>SourceY</i> is not zero then <i>Delta</i> must be set to the length in bytes of a row in the <i>BltBuffer</i> .
EfiBltVideoToVideo	Copy from the video display rectangle (<i>SourceX</i> , <i>SourceY</i>) (<i>SourceX</i> + <i>Width</i> , <i>SourceY</i> + <i>Height</i>) to the video display rectangle (<i>DestinationX</i> , <i>DestinationY</i>) (<i>DestinationX</i> + <i>Width</i> , <i>DestinationY</i> + <i>Height</i>). The <i>BltBuffer</i> and <i>Delta</i> are not used in this mode. There is no limitation on the overlapping of the source and destination rectangles.

Status Codes Returned

EFI_SUCCESS	<i>BltBuffer</i> was drawn to the graphics screen.
EFI_INVALID_PARAMETER	<i>BltOperation</i> is not valid.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.

EFI_EDID_DISCOVERED_PROTOCOL

Summary

This protocol contains the EDID information retrieved from a video output device.

GUID

```
#define EFI_EDID_DISCOVERED_PROTOCOL_GUID \
    {0x1c0c34f6,0xd380,0x41fa, \
     {0xa0,0x49,0x8a,0xd0,0x6c,0x1a,0x66,0xaa}}
```

Protocol Interface Structure

```
typedef struct {
    UINT32    SizeOfEdid;
    UINT8     *Edid;
} EFI_EDID_DISCOVERED_PROTOCOL;
```

Parameter

<i>SizeOfEdid</i>	The size, in bytes, of the <i>Edid</i> buffer. 0 if no EDID information is available from the video output device. Otherwise, it must be a minimum of 128 bytes.
<i>Edid</i>	A pointer to a read-only array of bytes that contains the EDID information for a video output device. This pointer is NULL if no EDID information is available from the video output device. The minimum size of a valid <i>Edid</i> buffer is 128 bytes. EDID

information is defined in the E-EDID EEPROM specification published by VESA (www.vesa.org).

Description

EFI_EDID_DISCOVERED_PROTOCOL represents the EDID information that is returned from a video output device. If the video output device does not contain any EDID information, then the *SizeOfEdid* field must set to zero and the *Edid* field must be set to **NULL**. The **EFI_EDID_DISCOVERED_PROTOCOL** must be placed on every child handle that represents a possible video output device. The **EFI_EDID_DISCOVERED_PROTOCOL** is never placed on child handles that represent combinations of two or more video output devices.

EFI_EDID_ACTIVE_PROTOCOL

Summary

This protocol contains the EDID information for an active video output device. This is either the EDID information retrieved from the **EFI_EDID_OVERRIDE_PROTOCOL** if an override is available, or an identical copy of the EDID information from the **EFI_EDID_DISCOVERED_PROTOCOL** if no overrides are available.

GUID

```
#define EFI_EDID_ACTIVE_PROTOCOL_GUID \
    { 0xbd8c1056, 0x9f36, 0x44ec, \
      0x92, 0xa8, 0xa6, 0x33, 0x7f, 0x81, 0x79, 0x86 }
```

Protocol Interface Structure

```
typedef struct {
    UINT32    SizeOfEdid;
    UINT8     *Edid;
} EFI_EDID_ACTIVE_PROTOCOL;
```

Parameter

<i>SizeOfEdid</i>	The size, in bytes, of the <i>Edid</i> buffer. 0 if no EDID information is available from the video output device. Otherwise, it must be a minimum of 128 bytes.
<i>Edid</i>	A pointer to a read-only array of bytes that contains the EDID information for an active video output device. This pointer is NULL if no EDID information is available for the video output device. The minimum size of a valid <i>Edid</i> buffer is 128 bytes. EDID information is defined in the E-EDID EEPROM specification published by VESA (www.vesa.org).

Description

When the set of active video output devices attached to a frame buffer are selected, the **EFI_EDID_ACTIVE_PROTOCOL** must be installed onto the handles that represent the each of

those active video output devices. If the `EFI_EDID_OVERRIDE_PROTOCOL` has override EDID information for an active video output device, then the EDID information specified by `GetEdid()` is used for the `EFI_EDID_ACTIVE_PROTOCOL`. Otherwise, the EDID information from the `EFI_EDID_DISCOVERED_PROTOCOL` is used for the `EFI_EDID_ACTIVE_PROTOCOL`. Since all EDID information is read-only, it is legal for the pointer associated with the `EFI_EDID_ACTIVE_PROTOCOL` to be the same as the pointer associated with the `EFI_EDID_DISCOVERED_PROTOCOL` when no overrides are present.

EFI_EDID_OVERRIDE_PROTOCOL

Summary

This protocol is produced by the platform to allow the platform to provide EDID information to the producer of the Graphics Output protocol.

GUID

```
#define EFI_EDID_OVERRIDE_PROTOCOL_GUID \
    {0x48ecb431,0xfb72,0x45c0,\
     {0xa9,0x22,0xf4,0x58,0xfe,0x04,0x0b,0xd5}}
```

Protocol Interface Structure

```
typedef struct _EFI_EDID_OVERRIDE_PROTOCOL {
    EFI_EDID_OVERRIDE_PROTOCOL_GET_EDID GetEdid;
} EFI_EDID_OVERRIDE_PROTOCOL;
```

Parameter

GetEdid Returns EDID values and attributes that the Video BIOS must use

Description

This protocol is produced by the platform to allow the platform to provide EDID information to the producer of the Graphics Output protocol.

EFI_EDID_OVERRIDE_PROTOCOL.GetEdid()

Summary

Returns policy information and potentially a replacement EDID for the specified video output device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EDID_OVERRIDE_PROTOCOL_GET_EDID) (
    IN     EFI_EDID_OVERRIDE_PROTOCOL  *This,
    IN     EFI_HANDLE                  *ChildHandle,
    OUT    UINT32                       *Attributes,
    IN OUT UINTN                       *EdidSize,
    IN OUT UINT8                       **Edid
);
```

Parameters

<i>This</i>	The EFI_EDID_OVERRIDE_PROTOCOL instance. Type EFI_EDID_OVERRIDE_PROTOCOL is defined in Section 11.10 .
<i>ChildHandle</i>	A child handle that represents a possible video output device.
<i>Attributes</i>	A pointer to the attributes associated with <i>ChildHandle</i> video output device.
<i>EdidSize</i>	A pointer to the size, in bytes, of the <i>Edid</i> buffer.
<i>Edid</i>	A pointer to the callee allocated buffer that contains the EDID information associated with <i>ChildHandle</i> . If <i>EdidSize</i> is 0, then a pointer to NULL is returned.

Related Definitions

```
#define EFI_EDID_OVERRIDE_DONT_OVERRIDE  0x01
#define EFI_EDID_OVERRIDE_ENABLE_HOT_PLUG 0x02
```

Table 107. Attributes Definition Table

Attribute Bit	EdidSize	Operation
<code>EFI_EDID_OVERRIDE_DONT_OVERRIDE=0</code>	0	No override support for the display device.
<code>EFI_EDID_OVERRIDE_DONT_OVERRIDE=0</code>	!= 0	Always use returned override EDID for the display device.
<code>EFI_EDID_OVERRIDE_DONT_OVERRIDE!=0</code>	0	No override support for the display device.
<code>EFI_EDID_OVERRIDE_DONT_OVERRIDE!=0</code>	!= 0	Only use returned override EDID if the display device has no EDID or the EDID is incorrect. Otherwise, use the EDID from the display device.

Attribute Bit	EdidSize	Operation
EFI_EDID_OVERRIDE_ENABLE_HOT_PLUG=0	0	No hot plug support for the display device. A Graphics Output protocol will not be installed if no display device is not present.
EFI_EDID_OVERRIDE_ENABLE_HOT_PLUG=0	!= 0	No hot plug support for the display device. The returned override EDID should be used according to the EFI_EDID_OVERRIDE_DONT_OVERRIDE attribute bit if the display device is present.
EFI_EDID_OVERRIDE_ENABLE_HOT_PLUG!=0	0	Invalid. The client of this protocol will not enable hot plug for the display device, and a Graphics Output protocol will not be installed if no other display is present.
EFI_EDID_OVERRIDE_ENABLE_HOT_PLUG!=0	!= 0	Enable hot plug for the display device. A Graphics Output protocol will be installed even if the display device is not present.

Description

This protocol is optionally provided by the platform to override or provide EDID information and/or output device display properties to the producer of the Graphics Output protocol. If *ChildHandle* does not represent a video output device, or there are no override for the video output device specified by *ChildHandle*, then **EFI_UNSUPPORTED** is returned. Otherwise, the *Attributes*, *EdidSize*, and *Edid* parameters are returned along with a status of **EFI_SUCCESS**. [Table 107](#) defines the behavior for the combinations of the *Attribute* and *EdidSize* parameters when **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	Valid over rides returned for <i>ChildHandle</i> .
EFI_UNSUPPORTED	<i>ChildHandle</i> has no over rides.

11.10 Rules for PCI/AGP Devices

A UEFI driver that produces the Graphics Output Protocol must follow the UEFI driver model, produce an **EFI DRIVER BINDING PROTOCOL**, and follow the rules on implementing the **Supported()**, **Start()**, and **Stop()**. The **Start()** function must not update the video output device in any way that is visible to the user. The **Start()** function must create child handle for each physical video output device and each supported combination of video output devices. The driver must retrieve the EDID information from each physical video output device and produce a **EFI EDID DISCOVERED PROTOCOL** on the child handle that corresponds each physical video output device. The following summary describes the common initialization steps for a driver that produces the **EFI_GRAPHICS_OUTPUT_PROTOCOL**. This summary assumes the graphics

controller supports a single frame buffer. If a graphics device supports multiple frame buffers, then handles for the frame buffers must be created first, and then the handles for the video output devices can be created as children of the frame buffer handles.

Summary of Initialization Steps:

- "If *RemainingDevicePath* is **NULL** or the first Device Path Node is the End of Device Path Node, then **Supported()** returns **EFI_SUCCESS**. Otherwise, if the first node of *RemainingDevicePath* is not an ACPI _ADR node or the first two nodes of *RemainingDevicePath* are not a Controller node followed by an ACPI _ADR node, then **Supported()** returns **EFI_UNSUPPORTED**.
- "If **Supported()** returned **EFI_SUCCESS**, system calls **Start()**.
- "If *RemainingDevicePath* is **NULL**, then a default set of active video output devices are selected by the driver.
- "If the first Device Path Node of *RemainingDevicePath* is the End of Device Path Node, then skip to the "The EFI Driver must provide **EFI_COMPONENT_NAME2_PROTOCOL**" step.
- **Start()** function creates a *ChildHandle* for each physical video output device and installs the **EFI_DEVICE_PATH_PROTOCOL** onto the created *ChildHandle*. The **EFI_DEVICE_PATH_PROTOCOL** is constructed by appending an ACPI _ADR device path node describing the physical video output device to the end of the device path installed on the *ControllerHandle* passed into **Start()**.
- **Start()** function retrieves EDID information for each physical video output device and installs the **EFI_EDID_DISCOVERED_PROTOCOL** onto the *ChildHandle* for each physical video output device. If no EDID data is available from the video output device, then *SizeOfEdid* is set to zero, and *Edid* is set to **NULL**.
- **Start()** function create a *ChildHandle* for each valid combination of two or more video output devices, and installs the **EFI_DEVICE_PATH_PROTOCOL** onto the created *ChildHandle*. The **EFI_DEVICE_PATH_PROTOCOL** is constructed by appending an ACPI _ADR device path node describing the combination of video output devices to the end of the device path installed on the *ControllerHandle* passed into **Start()**. The ACPI _ADR entry can represent complex topologies of devices and it is possible to have more than one ACPI _ADR entry in a single device path node. Support of complex video output device topologies is an optional feature.
- **Start()** function evaluates the *RemainingDevicePath* to select the set of active video output devices. If *RemainingDevicePath* is **NULL**, then **Start()** selects a default set of video output devices. If *RemainingDevicePath* is not **NULL**, and ACPI _ADR device path node of *RemainingDevicePath* does not match any of the created *ChildHandles*, then **Start()** must destroy all its *ChildHandles* and return **EFI_UNSUPPORTED**. Otherwise, **Start()** selects the set of active video output devices specified by the ACPI _ADR device path node in *RemainingDevicePath*.
- **Start()** retrieves the *ChildHandle* associated with each active video output device. Only *ChildHandles* that represent a physical video output device are considered. **Start()** calls the **EFI_EDID_OVERRIDE_PROTOCOL.GetEdid()** service passing in *ChildHandle*. Depending on the return values from **GetEdid()**, either the override EDID information or the EDID information from the **EFI_EDID_DISCOVERED_PROTOCOL** on *ChildHandle* is selected. See **GetEdid()** for a detailed description of this decision. The selected EDID

information is used to produce the **EFI_EDID_ACTIVE_PROTOCOL**, and that protocol is installed onto *ChildHandle*.

- **Start()** retrieves the one *ChildHandle* that represents the entire set of active video output devices. If this set is a single video output device, then this *ChildHandle* will be the same as the one used in the previous step. If this set is a combination of video output devices, then this will not be one of the *ChildHandles* used in the previous two steps. The **EFI_GRAPHICS_OUTPUT_PROTOCOL** is installed onto this *ChildHandle*.
- The **QueryMode()** service of the **EFI_GRAPHICS_OUTPUT_PROTOCOL** returns the set of modes that both the graphics controller and the set of active video output devices all support. If a different set of active video output device is selected, then a different set of modes will likely be produced by **QueryMode()**.
- **Start()** function optionally initializes video frame buffer hardware. The EFI driver has the option of delaying this operation until **SetMode()** is called.
- The EFI Driver must provide **EFI_COMPONENT_NAME2_PROTOCOL** **GetControllerName()** support for *ControllerHandle* and all the *ChildHandles* created by this driver. The name returned for *ControllerHandle* must return the name of the graphics device. The name returned for each of the *ChildHandles* allow the user to pick output display settings and should be constructed with this in mind.
- The EFI Driver's **Stop()** function must cleanly undo what the **Start()** function created.
- An **EFI_GRAPHICS_OUTPUT_PROTOCOL** must be implemented for every video frame buffer that exists on a video adapter. In most cases there will be a single **EFI_GRAPHICS_OUTPUT_PROTOCOL** placed on one of the a children of the *ControllerHandle* passed into the **EFI_DRIVER_BINDING.Start()** function.

If a single PCI device/function contains multiple frame buffers the **EFI_GRAPHICS_OUTPUT_PROTOCOL** must create child handles of the PCI handle that inherit its PCI device path and appends a controller device path node. The handles for the video output devices are children of the handles that represent the frame buffers.

A video device can support an arbitrary number of geometries, but it must support one or more of the following modes to conform to this specification:

Onboard graphics device

- A mode required in a platform design guide
- Native mode of the display

Plug in graphics device

- A mode required in a platform design guide
- 800 x 600 with 32-bit color depth or 640 x 480 with 32-bit color depth and a pixel format described by **PixelRedGreenBlueReserved8BitPerColor** or **PixelBlueGreenRedReserved8BitPerColor**.

If graphics output device supports both landscape and portrait mode displays it must return a different mode via **QueryMode()**. For example landscape mode could be 800 horizontal and 600 vertical while the equivalent portrait mode would be 600 horizontal and 800 vertical.

Protocols — Media Access

12.1 Load File Protocol

The Load File protocol is designed to allow code running in the boot services environment to find and load other modules of code.

EFI_LOAD_FILE_PROTOCOL

Summary

Used to obtain files from arbitrary devices.

GUID

```
#define EFI_LOAD_FILE_PROTOCOL_GUID \
    {0x56EC3091,0x954C,0x11d2,\
     {0x8e,0x3f,0x00,0xa0, 0xc9,0x69,0x72,0x3b}}
```

Protocol Interface Structure

```
typedef struct _EFI_LOAD_FILE_PROTOCOL {
    EFI_LOAD_FILE          LoadFile;
} EFI_LOAD_FILE_PROTOCOL;
```

Parameters

LoadFile Causes the driver to load the requested file. See the [LoadFile\(\)](#) function description.

Description

The **EFI_LOAD_FILE_PROTOCOL** is a simple protocol used to obtain files from arbitrary devices. When the firmware is attempting to load a file, it first attempts to use the device's Simple File System protocol to read the file. If the file system protocol is found, the firmware implements the policy of interpreting the File Path value of the file being loaded. If the device does not support the file system protocol, the firmware then attempts to read the file via the **EFI_LOAD_FILE_PROTOCOL** and the **LoadFile()** function. In this case the **LoadFile()** function implements the policy of interpreting the File Path value.

EFI_LOAD_FILE_PROTOCOL.LoadFile()

Summary

Causes the driver to load a specified file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_LOAD_FILE) (
    IN EFI_LOAD_FILE_PROTOCOL    *This,
    IN EFI_DEVICE_PATH_PROTOCOL  *FilePath,
    IN BOOLEAN                   BootPolicy,
    IN OUT UINTN                 *BufferSize,
    IN VOID                      *Buffer    OPTIONAL
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_LOAD_FILE_PROTOCOL is defined in Section 12.1 .
<i>FilePath</i>	The device specific path of the file to load. Type EFI_DEVICE_PATH_PROTOCOL is defined in Section 9.2 .
<i>BootPolicy</i>	If TRUE , indicates that the request originates from the boot manager, and that the boot manager is attempting to load <i>FilePath</i> as a boot selection. If FALSE , then <i>FilePath</i> must match an exact file to be loaded.
<i>BufferSize</i>	On input the size of <i>Buffer</i> in bytes. On output with a return code of EFI_SUCCESS , the amount of data transferred to <i>Buffer</i> . On output with a return code of EFI_BUFFER_TOO_SMALL , the size of <i>Buffer</i> required to retrieve the requested file.
<i>Buffer</i>	The memory buffer to transfer the file to. If <i>Buffer</i> is NULL , then the size of the requested file is returned in <i>BufferSize</i> .

Description

The **LoadFile()** function interprets the device-specific *FilePath* parameter, returns the entire file into *Buffer*, and sets *BufferSize* to the amount of data returned. If *Buffer* is **NULL**, then the size of the file is returned in *BufferSize*. If *Buffer* is not **NULL**, and *BufferSize* is not large enough to hold the entire file, then **EFI_BUFFER_TOO_SMALL** is returned, and *BufferSize* is updated to indicate the size of the buffer needed to obtain the file. In this case, no data is returned in *Buffer*.

If *BootPolicy* is **FALSE** the *FilePath* must match an exact file to be loaded. If no such file exists, **EFI_NOT_FOUND** is returned. If *BootPolicy* is **FALSE**, and an attempt is being made to perform a network boot through the PXE Base Code protocol, **EFI_UNSUPPORTED** is returned.

If *BootPolicy* is **TRUE** the firmware's boot manager is attempting to load an EFI image that is a boot selection. In this case, *FilePath* contains the file path value in the boot selection option.

Normally the firmware would implement the policy on how to handle an inexact boot file path; however, since in this case the firmware cannot interpret the file path, the **LoadFile()** function is responsible for implementing the policy. For example, in the case of a network boot through the PXE Base Code protocol, *FilePath* merely points to the root of the device, and the firmware interprets this as wanting to boot from the first valid loader. The following is a list of events that **LoadFile()** will implement for a PXE boot:

- Perform DHCP.
- Optionally prompt the user with a menu of boot selections.
- Discover the boot server and the boot file.
- Download the boot file into *Buffer* and update *BufferSize* with the size of the boot file.

If the boot file downloaded from boot server is not an UEFI-formatted executable, but a binary image which contains a UEFI-compliant file system, then **EFI_WARN_FILE_SYSTEM** is returned, and a new RAM disk mapped on the returned *Buffer* is registered.

Status Codes Returned

EFI_SUCCESS	The file was loaded.
EFI_UNSUPPORTED	The device does not support the provided <i>BootPolicy</i> .
EFI_INVALID_PARAMETER	<i>FilePath</i> is not a valid device path, or <i>BufferSize</i> is NULL .
EFI_NO_MEDIA	No medium was present to load the file.
EFI_DEVICE_ERROR	The file was not loaded due to a device error.
EFI_NO_RESPONSE	The remote system did not respond.
EFI_NOT_FOUND	The file was not found.
EFI_ABORTED	The file load process was manually cancelled.
EFI_BUFFER_TOO_SMALL	The <i>BufferSize</i> is too small to read the current directory entry. <i>BufferSize</i> has been updated with the size needed to complete the request.
EFI_WARN_FILE_SYSTEM	The resulting <i>Buffer</i> contains UEFI-compliant file system.

12.2 Load File 2 Protocol

The Load File 2 protocol is used to obtain files from arbitrary devices that are not boot options.

EFI_LOAD_FILE2_PROTOCOL

Summary

Used to obtain files from arbitrary devices but are not used as boot options.

GUID

```
#define EFI_LOAD_FILE2_PROTOCOL_GUID \  
    { 0x4006c0c1, 0xfcb3, 0x403e, \  
      { 0x99, 0x6d, 0x4a, 0x6c, 0x87, 0x24, 0xe0, 0x6d } }
```

Protocol Interface Structure

```
typedef EFI_LOAD_FILE_PROTOCOL EFI_LOAD_FILE2_PROTOCOL;
```

Parameters

LoadFile

Causes the driver to load the requested file. See the **LoadFile()** functional description.

Description

The **EFI_LOAD_FILE2_PROTOCOL** is a simple protocol used to obtain files from arbitrary devices that are not boot options. It is used by **LoadImage()** when its *BootOption* parameter is **FALSE** and the *FilePath* does not have an instance of the **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL**.

EFI_LOAD_FILE2_PROTOCOL.LoadFile()

Summary

Causes the driver to load a specified file.

Prototype

The same prototype as `EFI_LOAD_FILE_PROTOCOL.LoadFile()`.

Parameters

This

Indicates a pointer to the calling context.

FilePath

The device specific path of the file to load.

BootPolicy

Should always be **FALSE**.

BufferSize

On input the size of *Buffer* in bytes. On output with a return code of **EFI_SUCCESS**, the amount of data transferred to *Buffer*. On output with a return code of **EFI_BUFFER_TOO_SMALL**, the size of *Buffer* required to retrieve the requested file.

Buffer

The memory buffer to transfer the file to. If *Buffer* is **NULL**, then no the size of the requested file is returned in *BufferSize*.

Description

The **LoadFile()** function interprets the device-specific *FilePath* parameter, returns the entire file into *Buffer*, and sets *BufferSize* to the amount of data returned. If *Buffer* is **NULL**, then the size of the file is returned in *BufferSize*. If *Buffer* is not **NULL**, and *BufferSize* is not large enough to hold the entire file, then **EFI_BUFFER_TOO_SMALL** is returned, and *BufferSize* is updated to indicate the size of the buffer needed to obtain the file. In this case, no data is returned in *Buffer*.

FilePath contains the file path value in the boot selection option. Normally the firmware would implement the policy on how to handle an inexact boot file path; however, since in this case the firmware cannot interpret the file path, the **LoadFile()** function is responsible for implementing the policy.

Status Codes Returned

EFI_SUCCESS	The file was loaded.
EFI_UNSUPPORTED	BootPolicy is TRUE.
EFI_INVALID_PARAMETER	FilePath is not a valid device path, or BufferSize is NULL.
EFI_NO_MEDIA	No medium was present to load the file.
EFI_DEVICE_ERROR	The file was not loaded due to a device error.
EFI_NO_RESPONSE	The remote system did not respond.
EFI_NOT_FOUND	The file was not found.
EFI_ABORTED	The file load process was manually cancelled.
EFI_BUFFER_TOO_SMALL	The BufferSize is too small to read the current directory entry. BufferSize has been updated with the size needed to complete the request.

12.3 File System Format

The file system supported by the Extensible Firmware Interface is based on the FAT file system. EFI defines a specific version of FAT that is explicitly documented and testable. Conformance to the EFI specification and its associate reference documents is the only definition of FAT that needs to be implemented to support EFI. To differentiate the EFI file system from pure FAT, a new partition file system type has been defined.

EFI encompasses the use of FAT32 for a system partition, and FAT12 or FAT16 for removable media. The FAT32 system partition is identified by an OSType value other than that used to identify previous versions of FAT. This unique partition type distinguishes an EFI defined file system from a normal FAT file system. The file system supported by EFI includes support for long file names.

The definition of the EFI file system will be maintained by specification and will not evolve over time to deal with errata or variant interpretations in OS file system drivers or file system utilities. Future enhancements and compatibility enhancements to FAT will not be automatically included in EFI file systems. The EFI file system is a target that is fixed by the EFI specification, and other specifications explicitly referenced by the EFI specification.

For more information about the EFI file system and file image format, visit the web site from which this document was obtained.

12.3.1 System Partition

A System Partition is a partition in the conventional sense of a partition on a legacy system. For a hard disk, a partition is a contiguous grouping of sectors on the disk where the starting sector and size are defined by the Master Boot Record (MBR), which resides on LBA 0 (i.e., the first sector of the hard disk) (see [Section 5.2](#)), or the GUID Partition Table (GPT), which resides on logical block 1 (the second sector of the hard disk) (see [Section 5.3.1](#)). For a diskette (floppy) drive, a partition is defined to be the entire media. A System Partition can reside on any media that is supported by EFI Boot Services.

A System Partition supports backward compatibility with legacy systems by reserving the first block (sector) of the partition for compatibility code. On legacy systems, the first block (sector) of a partition is loaded into memory and execution is transferred to this code. EFI firmware does not

execute the code in the MBR. The EFI firmware contains knowledge about the partition structure of various devices, and can understand legacy MBR, GPT, and “El Torito.”

The System Partition contains directories, data files, and UEFI Images. UEFI Images can contain a OS Loader, an driver to extend platform firmware capability, or an application that provides a transient service to the system. Applications written to this specification could include things such as a utility to create partitions or extended diagnostics. A System Partition can also support data files, such as error logs, that can be defined and used by various OS or system firmware software components.

12.3.1.1 File System Format

The first block (sector) of a partition contains a data structure called the BIOS Parameter Block (BPB) that defines the type and location of FAT file system on the drive. The BPB contains a data structure that defines the size of the media, the size of reserved space, the number of FAT tables, and the location and size of the root directory (not used in FAT32). The first block (sector) also contains code that will be executed as part of the boot process on a legacy system. This code in the first block (sector) usually contains code that can read a file from the root directory into memory and transfer control to it. Since EFI firmware contains a file system driver, EFI firmware can load any file from the file system with out needing to execute any code from the media.

The EFI firmware must support the FAT32, FAT16, and FAT12 variants of the EFI file system. What variant of EFI FAT to use is defined by the size of the media. The rules defining the relationship between media size and FAT variants is defined in the specification for the EFI file system.

The UEFI system partition FAT32 Data region should be aligned to the physical block boundary and optimal transfer length granularity of the device(see [Section 5.3.1](#)). This is controlled by the BPB_RsvdSecCnt field and the applicable BPB_FATSz field (e.g., formatting software may set the BPB_RsvdSecCnt field to a value that results in alignment and/or may set the BPB_FATSz field to a value that ensures alignment).

12.3.1.2 File Names

FAT stores file names in two formats. The original FAT format limited file names to eight characters with three extension characters. This type of file name is called an 8.3, pronounced eight dot three, file name. FAT was extended to include support for long file names (LFN).

FAT 8.3 file names are always stored as uppercase ASCII characters. LFN can either be stored as ASCII or UCS-2 characters and are stored case sensitive. The string that was used to open or create the file is stored directly into LFN. FAT defines that all files in a directory must have a unique name, and unique is defined as a case insensitive match. The following are examples of names that are considered to be the same and cannot exist in a single directory:

- “ThisIsAnExampleDirectory.Dir”
- “thisisanexamppledirectory.dir”
- THISISANEXAMPLEDIRECTORY.DIR
- ThisIsAnExampleDirectory.DIR

Note: Although the FAT32 specification allows file names to be encoded using UTF-16, this specification only recognizes the UCS-2 subset for the purposes of sorting or collation.

12.3.1.3 Directory Structure

An EFI system partition that is present on a hard disk must contain an EFI defined directory in the root directory. This directory is named **EFI**. All OS loaders and applications will be stored in subdirectories below **EFI**. Applications that are loaded by other applications or drivers are not required to be stored in any specific location in the EFI system partition. The choice of the subdirectory name is up to the vendor, but all vendors must pick names that do not collide with any other vendor's subdirectory name. This applies to system manufacturers, operating system vendors, BIOS vendors, and third party tool vendors, or any other vendor that wishes to install files on an EFI system partition. There must also only be one executable EFI image for each supported processor architecture in each vendor subdirectory. This guarantees that there is only one image that can be loaded from a vendor subdirectory by the EFI Boot Manager. If more than one executable EFI image is present, then the boot behavior for the system will not be deterministic. There may also be an optional vendor subdirectory called **BOOT**.

This directory contains EFI images that aid in recovery if the boot selections for the software installed on the EFI system partition are ever lost. Any additional UEFI-compliant executables must be in subdirectories below the vendor subdirectory. The following is a sample directory structure for an EFI system partition present on a hard disk.

```

\EFI
  \<OS Vendor 1 Directory>
    <OS Loader Image>
  \<OS Vendor 2 Directory>
    <OS Loader Image>
  . . .
  \<OS Vendor N Directory>
    <OS Loader Image>
  \<OEM Directory>
    <OEM Application Image>
  \<BIOS Vendor Directory>
    <BIOS Vendor Application Image>
  \<Third Party Tool Vendor Directory>
    <Third Party Tool Vendor Application Image>
\BOOT
  BOOT{machine type short name}.EFI

```

For removable media devices there must be only one UEFI-compliant system partition, and that partition must contain an UEFI-defined directory in the root directory. The directory will be named **EFI**. All OS loaders and applications will be stored in a subdirectory below **EFI** called **BOOT**. There must only be one executable EFI image for each supported processor architecture in the **BOOT** directory. For removable media to be bootable under EFI, it must be built in accordance with the rules laid out in [Section 3.5.1.1](#). This guarantees that there is only one image that can be automatically loaded from a removable media device by the EFI Boot Manager. Any additional EFI executables must be in directories other than **BOOT**. The following is a sample directory structure for an EFI system partition present on a removable media device.

```

\EFI
  \BOOT
    BOOT{machine type short name}.EFI
  
```

12.3.2 Partition Discovery

This specification requires the firmware to be able to parse the legacy master boot record(MBR) (see [Section 5.2.1](#)), GUID Partition Table (GPT)(see [Section 5.3.1](#)), and El Torito (see [Section 12.3.2.1](#)) logical device volumes. The EFI firmware produces a logical [EFI BLOCK IO PROTOCOL](#) device for:

- each GUID Partition Entry (see table 16 in 5.3.3) with bit 1 set to zero;
- each El Torito logical device volume; and
- if no GPT is present, each partition found in the legacy MBR partition tables.

LBA zero of the [EFI_BLOCK_IO_PROTOCOL](#) device will correspond to the first logical block of the partition. See [Figure 30](#). If a GPT Partition Entry has Attribute bit 1 set then a logical [EFI_BLOCK_IO_PROTOCOL](#) device must not be created.

OM13159

Figure 30. Nesting of Legacy MBR Partition Records

The following is the order in which a block device must be scanned to determine if it contains partitions. When a check for a valid partitioning scheme succeeds, the search terminates.

1. Check for GUID Partition Table Headers.
2. Follow ISO-9660 specification to search for ISO-9660 volume structures on the magic LBA.
3. Check for an “El Torito” volume extension and follow the “El Torito” CD-ROM specification.
4. If none of the above, check LBA 0 for a legacy MBR partition table.
5. No partition found on device.

If a disk contains a recognized RAID structure (e.g. DDF structure as defined in *The Storage Networking Industry Association Common RAID Disk Data Format Specification*--see Glossary), the data on the disk must be ignored, unless the driver is using the RAID structure to produce a logical RAID volume.

EFI supports the nesting of legacy MBR partitions, by allowing any legacy MBR partition to contain more legacy MBR partitions. This is accomplished by supporting the same partition discovery algorithm on every logical block device. It should be noted that the GUID Partition Table does not allow nesting of GUID Partition Table Headers. Nesting is not needed since a GUID Partition Table Header can support an arbitrary number of partitions (the addressability limits of a 64-bit LBA are the limiting factor).

12.3.2.1 ISO-9660 and El Torito

ISO-9660 is the industry standard low level format used on CD-ROM and DVD-ROM. The CD-ROM format is completely described by the “El Torito” Bootable CD-ROM Format Specification Version 1.0. To boot from a CD-ROM or DVD-ROM in the boot services environment, an EFI System partition is stored in a “no emulation” mode as defined by the “El Torito” specification. A Platform ID of 0xEF indicates an EFI System Partition. The Platform ID is in either the Section Header Entry or the Validation Entry of the Booting Catalog as defined by the “El Torito” specification. EFI differs from “El Torito” “no emulation” mode in that it does not load the “no emulation” image into memory and jump to it. EFI interprets the “no emulation” image as an EFI system partition. EFI interprets the Sector Count in the Initial/Default Entry or the Section Header Entry to be the size of the EFI system partition. If the value of Sector Count is set to 0 or 1, EFI will assume the system partition consumes the space from the beginning of the “no emulation” image to the end of the CD-ROM.

DVD-ROM images formatted as required by the UDF 2.0 specification (*OSTA Universal Disk Format Specification*, Revision 2.0) can be booted by EFI. EFI supports booting from an ISO-9660 file system that conforms to the “El Torito” Bootable CD-ROM Format Specification on a DVD-ROM. A DVD-ROM that contains an ISO-9660 file system is defined as a “UDF Bridge” disk. Booting from CD-ROM and DVD-ROM is accomplished using the same methods.

Since the EFI file system definition does not use the same Initial/Default entry as a legacy CD-ROM it is possible to boot personal computers using an EFI CD-ROM or DVD-ROM. The inclusion of boot code for personal computers is optional and not required by EFI.

12.3.3 Number and Location of System Partitions

UEFI does not impose a restriction on the number or location of System Partitions that can exist on a system. System Partitions are discovered when required by UEFI firmware by examining the partition GUID and verifying that the contents of the partition conform to the FAT file system as defined in [Section 12.3.1.1](#). Further, UEFI implementations may allow the use of conforming FAT partitions which do not use the ESP GUID. Partition creators may prevent UEFI firmware from examining and using a specific partition by setting bit 1 of the Partition Attributes (see 5.3.3) which will exclude the partition as a potential ESP.

Software installation may choose to create and locate an ESP on each target OS boot disk, or may choose to create a single ESP independent of the location of OS boot disks and OS partitions. It is outside of the scope of this specification to attempt to coordinate the specification of size and

location of an ESP that can be shared by multiple OS or Diagnostics installations, or to manage potential namespace collisions in directory naming in a single (central) ESP.

12.3.4 Media Formats

This section describes how booting from different types of removable media is handled. In general the rules are consistent regardless of a media's physical type and whether it is removable or not.

12.3.4.1 Removable Media

Removable media may contain a standard FAT12, FAT16, or FAT32 file system.

Bootting from a removable media device can be accomplished the same way as any other boot. The boot file path provided to the boot manager can consist of a UEFI application image to load, or can merely be the path to a removable media device. In the first case, the path clearly indicates the image that is to be loaded. In the later case, the boot manager implements the policy to load the default application image from the device.

For removable media to be bootable under EFI, it must be built in accordance with the rules laid out in [Section 3.5.1.1](#)

12.3.4.2 Diskette

EFI bootable diskettes follow the standard formatting conventions used on personal computers. The diskette contains only a single partition that complies to the EFI file system type. For diskettes to be bootable under EFI, it must be built in accordance with the rules laid out in [Section 3.5.1.1](#).

Since the EFI file system definition does not use the code in the first block of the diskette, it is possible to boot personal computers using a diskette that is also formatted as an EFI bootable removable media device. The inclusion of boot code for personal computers is optional and not required by EFI.

Diskettes include the legacy 3.5-inch diskette drives as well as the newer larger capacity removable media drives such as an Iomega* Zip*, Fujitsu MO, or MKE LS-120/SuperDisk*.

12.3.4.3 Hard Drive

Hard drives may contain multiple partitions as defined in [Section 12.3.2](#) on partition discovery. Any partition on the hard drive may contain a file system that the EFI firmware recognizes. Images that are to be booted must be stored under the EFI subdirectory as defined in [Section 12.3.1](#) and [Section 12.3.2](#).

EFI code does not assume a fixed block size.

Since EFI firmware does not execute the MBR code and does not depend on the *BootIndicator* field in the legacy MBR partition records, the hard disk can still boot and function normally.

12.3.4.4 CD-ROM and DVD-ROM

A CD-ROM or DVD-ROM may contain multiple partitions as defined [Section 12.3.1](#) and [Section 12.3.2](#) and in the “El Torito” specification.

EFI code does not assume a fixed block size.

Since the EFI file system definition does not use the same Initial/Default entry as a legacy CD-ROM, it is possible to boot personal computers using an EFI CD-ROM or DVD-ROM. The inclusion of boot code for personal computers is optional and not required by EFI.

12.3.4.5 Network

To boot from a network device, the Boot Manager uses the Load File Protocol to perform a [LoadFile\(\)](#) on the network device. This uses the PXE Base Code Protocol to perform DHCP and Discovery. This may result in a list of possible boot servers along with the boot files available on each server. The Load File Protocol for a network boot may then optionally produce a menu of these selections for the user to choose from. If this menu is presented, it will always have a timeout, so the Load File Protocol can automatically boot the default boot selection. If there is only one possible boot file, then the Load File Protocol can automatically attempt to load the one boot file.

The Load File Protocol will download the boot file using the MFTFTP service in the PXE Base Code Protocol. The downloaded image must be an EFI image that the platform supports.

12.4 Simple File System Protocol

The Simple File System protocol allows code running in the EFI boot services environment to obtain file based access to a device. **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL** is used to open a device volume and return an [EFI_FILE_PROTOCOL](#) that provides interfaces to access files on a device volume.

EFI_SIMPLE_FILE_SYSTEM_PROTOCOL

Summary

Provides a minimal interface for file-type access to a device.

GUID

```
#define EFI_SIMPLE_FILE_SYSTEM_PROTOCOL_GUID \
    {0x0964e5b22,0x6459,0x11d2,\
     {0x8e,0x39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Revision Number

```
#define EFI_SIMPLE_FILE_SYSTEM_PROTOCOL_REVISION    0x00010000
```

Protocol Interface Structure

```
typedef struct _EFI_SIMPLE_FILE_SYSTEM_PROTOCOL {
    UINT64                                     Revision;
    EFI_SIMPLE_FILE_SYSTEM_PROTOCOL_OPEN_VOLUME OpenVolume;
} EFI_SIMPLE_FILE_SYSTEM_PROTOCOL;
```

Parameters

Revision

The version of the **EFI_FILE_PROTOCOL**. The version specified by this specification is 0x00010000. All future revisions

OpenVolume

must be backwards compatible. If a future version is not backwards compatible, it is not the same GUID.

Opens the volume for file I/O access. See the [OpenVolume \(\)](#) function description.

Description

The **EFI_SIMPLE_FILE_SYSTEM_PROTOCOL** provides a minimal interface for file-type access to a device. This protocol is only supported on some devices.

Devices that support the Simple File System protocol return an **EFI_FILE_PROTOCOL**. The only function of this interface is to open a handle to the root directory of the file system on the volume. Once opened, all accesses to the volume are performed through the volume's file handles, using the [EFI_FILE_PROTOCOL](#) protocol. The volume is closed by closing all the open file handles.

The firmware automatically creates handles for any block device that supports the following file system formats:

- FAT12
- FAT16
- FAT32

EFI_SIMPLE_FILE_SYSTEM_PROTOCOL.OpenVolume()

Summary

Opens the root directory on a volume.

Prototype

```

typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL_OPEN_VOLUME) (
    IN EFI_SIMPLE_FILE_SYSTEM_PROTOCOL      *This,
    OUT EFI_FILE_PROTOCOL                   **Root
);

```

Parameters

<i>This</i>	A pointer to the volume to open the root directory of. See the type EFI_SIMPLE_FILE_SYSTEM_PROTOCOL description.
<i>Root</i>	A pointer to the location to return the opened file handle for the root directory. See the type EFI_FILE_PROTOCOL description.

Description

The **OpenVolume()** function opens a volume, and returns a file handle to the volume's root directory. This handle is used to perform all other file I/O operations. The volume remains open until all the file handles to it are closed.

If the medium is changed while there are open file handles to the volume, all file handles to the volume will return **EFI_MEDIA_CHANGED**. To access the files on the new medium, the volume must be reopened with **OpenVolume()**. If the new medium is a different file system than the one supplied in the **EFI_HANDLE**'s **DevicePath** for the **EFI_SIMPLE_SYSTEM_PROTOCOL**, **OpenVolume()** will return **EFI_UNSUPPORTED**.

Status Codes Returned

EFI_SUCCESS	The file volume was opened.
EFI_UNSUPPORTED	The volume does not support the requested file system type.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_ACCESS_DENIED	The service denied access to the file.
EFI_OUT_OF_RESOURCES	The file volume was not opened.
EFI_MEDIA_CHANGED	The device has a different medium in it or the medium is no longer supported. Any existing file handles for this volume are no longer valid. To access the files on the new medium, the volume must be reopened with OpenVolume () .

12.5 File Protocol

The protocol and functions described in this section support access to EFI-supported file systems.

EFI_FILE_PROTOCOL

Summary

Provides file based access to supported file systems.

Revision Number

```
#define EFI_FILE_PROTOCOL_REVISION          0x00010000
#define EFI_FILE_PROTOCOL_REVISION2       0x00020000
#define EFI_FILE_PROTOCOL_LATEST_REVISION
EFI_FILE_PROTOCOL_REVISION2
```

Protocol Interface Structure

```
typedef struct _EFI_FILE_PROTOCOL {
    UINT64                Revision;
    EFI_FILE_OPEN         Open;
    EFI_FILE_CLOSE        Close;
    EFI_FILE_DELETE       Delete;
    EFI_FILE_READ         Read;
    EFI_FILE_WRITE        Write;
    EFI_FILE_GET_POSITION GetPosition;
    EFI_FILE_SET_POSITION SetPosition;
    EFI_FILE_GET_INFO     GetInfo;
    EFI_FILE_SET_INFO     SetInfo;
    EFI_FILE_FLUSH        Flush;
    EFI_FILE_OPEN_EX      OpenEx; // Added for revision 2
    EFI_FILE_READ_EX      ReadEx; // Added for revision 2
    EFI_FILE_WRITE_EX     WriteEx; // Added for revision 2
    EFI_FILE_FLUSH_EX     FlushEx; // Added for revision 2
} EFI_FILE_PROTOCOL;
```

Parameters

<i>Revision</i>	The version of the EFI_FILE_PROTOCOL interface. The version specified by this specification is EFI_FILE_PROTOCOL_LATEST_REVISION . Future versions are required to be backward compatible to version 1.0.
<i>Open</i>	Opens or creates a new file. See the Open() function description.
<i>Close</i>	Closes the current file handle. See the Close() function description.
<i>Delete</i>	Deletes a file. See the Delete() function description.
<i>Read</i>	Reads bytes from a file. See the Read() function description.
<i>Write</i>	Writes bytes to a file. See the Write() function description.
<i>GetPosition</i>	Returns the current file position. See the GetPosition() function description.
<i>SetPosition</i>	Sets the current file position. See the SetPosition() function description.
<i>GetInfo</i>	Gets the requested file or volume information. See the GetInfo() function description.

<i>SetInfo</i>	Sets the requested file information. See the SetInfo() function description.
<i>Flush</i>	Flushes all modified data associated with the file to the device. See the Flush() function description.
<i>OpenEx</i>	Opens a new file relative to the source directory's location.
<i>ReadEx</i>	Reads data from a file.
<i>WriteEx</i>	Writes data to a file.
<i>FlushEx</i>	Flushes all modified data associated with a file to a device.

Description

The **EFI_FILE_PROTOCOL** provides file IO access to supported file systems.

An **EFI_FILE_PROTOCOL** provides access to a file's or directory's contents, and is also a reference to a location in the directory tree of the file system in which the file resides. With any given file handle, other files may be opened relative to this file's location, yielding new file handles.

On requesting the file system protocol on a device, the caller gets the **EFI_FILE_PROTOCOL** to the volume. This interface is used to open the root directory of the file system when needed. The caller must [Close\(\)](#) the file handle to the root directory, and any other opened file handles before exiting. While there are open files on the device, usage of underlying device protocol(s) that the file system is abstracting must be avoided. For example, when a file system that is layered on a [EFI_DISK_IO_PROTOCOL](#)/[EFI_BLOCK_IO_PROTOCOL](#), direct block access to the device for the blocks that comprise the file system must be avoided while there are open file handles to the same device.

A file system driver may cache data relating to an open file. A **Flush()** function is provided that flushes all dirty data in the file system, relative to the requested file, to the physical medium. If the underlying device may cache data, the file system must inform the device to flush as well.

Implementations must account for cases where there is pending queued asynchronous I/O when a call is received on a blocking protocol interface. In these cases the pending I/O will be processed and completed before the blocking function is executed so that operation are carried out in the order they were requested.

EFI_FILE_PROTOCOL.Open()

Summary

Opens a new file relative to the source file's location.

Prototype

```

typedef
EFI_STATUS
(EFI_API *EFI_FILE_OPEN) (
    IN EFI_FILE_PROTOCOL    *This,
    OUT EFI_FILE_PROTOCOL  **NewHandle,
    IN CHAR16               *FileName,
    IN UINT64               OpenMode,
    IN UINT64               Attributes
);

```

Parameters

<i>This</i>	A pointer to the EFI_FILE_PROTOCOL instance that is the file handle to the source location. This would typically be an open handle to a directory. See the type EFI_FILE_PROTOCOL description.
<i>NewHandle</i>	A pointer to the location to return the opened handle for the new file. See the type EFI_FILE_PROTOCOL description.
<i>FileName</i>	The Null-terminated string of the name of the file to be opened. The file name may contain the following path modifiers: “\”, “.”, and “..”.
<i>OpenMode</i>	The mode to open the file. The only valid combinations that the file may be opened with are: Read, Read/Write, or Create/Read/Write. See “Related Definitions” below.
<i>Attributes</i>	Only valid for EFI_FILE_MODE_CREATE , in which case these are the attribute bits for the newly created file. See “Related Definitions” below.

Related Definitions

```

//*****
// Open Modes

#define EFI_FILE_HIDDEN              0x0000000000000002
#define EFI_FILE_SYSTEM              0x0000000000000004
#define EFI_FILE_RESERVED           0x0000000000000008
#define EFI_FILE_DIRECTORY           0x0000000000000010
#define EFI_FILE_ARCHIVE             0x0000000000000020
#define EFI_FILE_VALID_ATTR         0x0000000000000037

```

Description

The **Open ()** function opens the file or directory referred to by *FileName* relative to the location of *This* and returns a *NewHandle*. The *FileName* may include the following path modifiers:

- “\” If the filename starts with a “\” the relative location is the root directory that *This* resides on; otherwise “\” separates name components. Each name component is opened in turn, and the handle to the last file opened is returned.
- “.” Opens the current location.
- “..” Opens the parent directory for the current location. If the location is the root directory the request will return an error, as there is no parent directory for the root directory.

If **EFI_FILE_MODE_CREATE** is set, then the file is created in the directory. If the final location of *FileName* does not refer to a directory, then the operation fails. If the file does not exist in the directory, then a new file is created. If the file already exists in the directory, then the existing file is opened.

If the medium of the device changes, all accesses (including the File handle) will result in **EFI_MEDIA_CHANGED**. To access the new medium, the volume must be reopened.

Status Codes Returned

EFI_SUCCESS	The file was opened.
EFI_NOT_FOUND	The specified file could not be found on the device.
EFI_NO_MEDIA	The device has no medium.
EFI_MEDIA_CHANGED	The device has a different medium in it or the medium is no longer supported.
EFI_DEVICE_ERROR	The device reported an error.

Unified Extensible Firmware Interface Specification

EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	An attempt was made to create a file, or open a file for write when the media is write-protected.
EFI_ACCESS_DENIED	The service denied access to the file.
EFI_OUT_OF_RESOURCES	Not enough resources were available to open the file.
EFI_VOLUME_FULL	The volume is full.

EFI_FILE_PROTOCOL.Close()

Summary

Closes a specified file handle.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_CLOSE) (
    IN EFI_FILE_PROTOCOL  *This
);
```

Parameters

This A pointer to the [EFI_FILE_PROTOCOL](#) instance that is the file handle to close. See the type [EFI_FILE_PROTOCOL](#) description.

Description

The **Close()** function closes a specified file handle. All “dirty” cached file data is flushed to the device, and the file is closed. In all cases the handle is closed. The operation will wait for all pending asynchronous I/O requests to complete before completing.

Status Codes Returned

EFI_SUCCESS	The file was closed.
-------------	----------------------

EFI_FILE_PROTOCOL.Delete()

Summary

Closes and deletes a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_DELETE) (
    IN EFI_FILE_PROTOCOL    *This
);
```

Parameters

This

A pointer to the [EFI_FILE_PROTOCOL](#) instance that is the handle to the file to delete. See the type [EFI_FILE_PROTOCOL](#) description.

Description

The **Delete()** function closes and deletes a file. In all cases the file handle is closed. If the file cannot be deleted, the warning code **EFI_WARN_DELETE_FAILURE** is returned, but the handle is still closed.

Status Codes Returned

EFI_SUCCESS	The file was closed and deleted, and the handle was closed.
EFI_WARN_DELETE_FAILURE	The handle was closed, but the file was not deleted.

EFI_FILE_PROTOCOL.Read()

Summary

Reads data from a file.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_FILE_READ) (
    IN EFI_FILE_PROTOCOL *This,
    IN OUT UINTN          *BufferSize,
    OUT VOID              *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_FILE_PROTOCOL instance that is the file handle to read data from. See the type EFI_FILE_PROTOCOL description.
<i>BufferSize</i>	On input, the size of the <i>Buffer</i> . On output, the amount of data returned in <i>Buffer</i> . In both cases, the size is measured in bytes.
<i>Buffer</i>	The buffer into which the data is read.

Description

The **Read()** function reads data from a file.

If *This* is not a directory, the function reads the requested number of bytes from the file at the file's current position and returns them in *Buffer*. If the read goes beyond the end of the file, the read length is truncated to the end of the file. The file's current position is increased by the number of bytes returned.

If *This* is a directory, the function reads the directory entry at the file's current position and returns the entry in *Buffer*. If the *Buffer* is not large enough to hold the current directory entry, then **EFI_BUFFER_TOO_SMALL** is returned and the current file position is *not* updated. *BufferSize* is set to be the size of the buffer needed to read the entry. On success, the current position is updated to the next directory entry. If there are no more directory entries, the read returns a zero-length buffer. [EFI_FILE_INFO](#) is the structure returned as the directory entry.

Status Codes Returned

EFI_SUCCESS	The data was read.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_DEVICE_ERROR	An attempt was made to read from a deleted file.
EFI_DEVICE_ERROR	On entry, the current file position is beyond the end of the file.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.

Unified Extensible Firmware Interface Specification

EFI_BUFFER_TOO_SMALL	The <i>BufferSize</i> is too small to read the current directory entry. <i>BufferSize</i> has been updated with the size needed to complete the request.
----------------------	--

EFI_FILE_PROTOCOL.Write()

Summary

Writes data to a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_WRITE) (
    IN EFI_FILE_PROTOCOL *This,
    IN OUT UINTN          *BufferSize,
    IN VOID               *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_FILE_PROTOCOL instance that is the file handle to write data to. See the type EFI_FILE_PROTOCOL description.
<i>BufferSize</i>	On input, the size of the <i>Buffer</i> . On output, the amount of data actually written. In both cases, the size is measured in bytes.
<i>Buffer</i>	The buffer of data to write.

Description

The **Write()** function writes the specified number of bytes to the file at the current file position. The current file position is advanced the actual number of bytes written, which is returned in *BufferSize*. Partial writes only occur when there has been a data error during the write attempt (such as “file space full”). The file is automatically grown to hold the data if required.

Direct writes to opened directories are not supported.

Status Codes Returned

EFI_SUCCESS	The data was written.
EFI_UNSUPPORTED	Writes to open directory files are not supported.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_DEVICE_ERROR	An attempt was made to write to a deleted file.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	The file or medium is write-protected.
EFI_ACCESS_DENIED	The file was opened read only.
EFI_VOLUME_FULL	The volume is full.

EFI_FILE_PROTOCOL.OpenEx()

Summary

Opens a new file relative to the source directory's location.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_OPEN) (
  IN EFI_FILE_PROTOCOL      *This,
  OUT EFI_FILE_PROTOCOL    **NewHandle,
  IN CHAR16                *FileName,
  IN UINT64                OpenMode,
  IN UINT64                Attributes,
  IN OUT EFI_FILE_IO_TOKEN *Token
);
```

Parameters

<i>This</i>	A pointer to the EFI_FILE_PROTOCOL instance that is the file handle to read data from. See the type EFI_FILE_PROTOCOL description.
<i>NewHandle</i>	A pointer to the location to return the opened handle for the new file. See the type EFI_FILE_PROTOCOL description. For asynchronous I/O, this pointer must remain valid for the duration of the asynchronous operation.
<i>FileName</i>	The Null-terminated string of the name of the file to be opened. The file name may contain the following path modifiers: “\”, “.”, and “..”.
<i>OpenMode</i>	The mode to open the file. The only valid combinations that the file may be opened with are: Read, Read/Write, or Create/Read/Write. See “Related Definitions” below.
<i>Attributes</i>	Only valid for EFI_FILE_MODE_CREATE , in which case these are the attribute bits for the
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_FILE_IO_TOKEN is defined in "Related Definitions" below.

Description

The **OpenEx()** function opens the file or directory referred to by *FileName* relative to the location of *This* and returns a *NewHandle*. The *FileName* may include the path modifiers described previously in **Open()**.

If **EFI_FILE_MODE_CREATE** is set, then the file is created in the directory. If the final location of *FileName* does not refer to a directory, then the operation fails. If the file does not exist in the directory, then a new file is created. If the file already exists in the directory, then the existing file is opened.

If the medium of the device changes, all accesses (including the *File* handle) will result in **EFI_MEDIA_CHANGED**. To access the new medium, the volume must be reopened.

If an error is returned from the call to **OpenEx()** and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled. If the call to **OpenEx()** succeeds then the *Event* will be signaled upon completion of the open or if an error occurs during the processing of the request. The status of the read request can be determined from the Status field of the Token once the event is signaled.

Related Definitions

```
typedef struct {
    EFI_EVENT      Event;
    EFI_STATUS     Status;
    UINTN          BufferSize;
    VOID          *Buffer;
} EFI_FILE_IO_TOKEN;
```

Event If *Event* is NULL, then blocking I/O is performed. If *Event* is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the read request is completed. The caller must be prepared to handle the case where the callback associated with *Event* occurs before the original asynchronous I/O request call returns.

Status Defines whether or not the signaled event encountered an error.

BufferSize For **OpenEx()**: Not Used, ignored
 For **ReadEx()**: On input, the size of the *Buffer*. On output, the amount of data returned in *Buffer*. In both cases, the size is measured in bytes.

For **WriteEx()**: On input, the size of the *Buffer*. On output, the amount of data actually written. In both cases, the size is measured in bytes.

For **FlushEx()**: Not used, ignored

Buffer For **OpenEx()**: Not Used, ignored

For **ReadEx()**: The buffer into which the data is read.

For **WriteEx()**: The buffer of data to write.

For **FlushEx()**: Not Used, ignored

Status Codes Returned

<p>EFI_SUCCESS</p>	<p>Returned from the call <i>OpenEx()</i> If <i>Event</i> is NULL (blocking I/O): The file was opened successfully. If <i>Event</i> is not NULL (asynchronous I/O): The request was successfully queued for processing. <i>Event</i> will be signaled upon completion. Returned in the token after signaling <i>Event</i> The file was opened successfully.</p>
--------------------	--

Unified Extensible Firmware Interface Specification

EFI_NOT_FOUND	The device has no medium.
EFI_NO_MEDIA	The specified file could not be found on the device.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	An attempt was made to create a file, or open a file for write when the media is write-protected.
EFI_ACCESS_DENIED	The service denied access to the file.
EFI_OUT_OF_RESOURCES	Unable to queue the request or open the file due to lack of resources.
EFI_VOLUME_FULL	The volume is full.

EFI_FILE_PROTOCOL.ReadEx()

Summary

Reads data from a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_READ_EX) (
    IN EFI_FILE_PROTOCOL      *This,
    IN OUT EFI_FILE_IO_TOKEN *Token
);
```

Parameters

<i>This</i>	A pointer to the EFI_FILE_PROTOCOL instance that is the file handle to read data from. See the type EFI_FILE_PROTOCOL description.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_FILE_IO_TOKEN is defined in "Related Definitions" below.

Description

The **ReadEx()** function reads data from a file.

If *This* is not a directory, the function reads the requested number of bytes from the file at the file's current position and returns them in *Buffer*. If the read goes beyond the end of the file, the read length is truncated to the end of the file. The file's current position is increased by the number of bytes returned.

If *This* is a directory, the function reads the directory entry at the file's current position and returns the entry in *Buffer*. If the *Buffer* is not large enough to hold the current directory entry, then **EFI_BUFFER_TOO_SMALL** is returned and the current file position is *not* updated. *BufferSize* is set to be the size of the buffer needed to read the entry. On success, the current position is updated to the next directory entry. If there are no more directory entries, the read returns a zero-length buffer. **EFI_FILE_INFO** is the structure returned as the directory entry.

If non-blocking I/O is used the file pointer will be advanced based on the order that read requests were submitted.

If an error is returned from the call to *ReadEx()* and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled. If the call to *ReadEx()* succeeds then the *Event* will be signaled upon completion of the read or if an error occurs during the processing of the request. The status of the read request can be determined from the *Status* field of the *Token* once the event is signaled.

Status Codes Returned

EFI_SUCCESS	<p>Returned from the call ReadEx ()</p> <p>If <i>Event</i> is NULL (blocking I/O): The data was read successfully.</p> <p>If <i>Event</i> is not NULL (asynchronous I/O): The request was successfully queued for processing. Event will be signaled upon completion. Returned in the token after signaling <i>Event</i> The data was read successfully.</p>
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_DEVICE_ERROR	An attempt was made to read from a deleted file.
EFI_DEVICE_ERROR	On entry, the current file position is beyond the end of the file.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_OUT_OF_RESOURCES	Unable to queue the request due to lack of resources.

EFI_FILE_PROTOCOL.WriteEx()

Summary

Writes data to a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_WRITE_EX) (
    IN EFI_FILE_PROTOCOL          *This,
    IN OUT EFI_FILE_IO_TOKEN     *Token
);
```

Parameters

<i>This</i>	A pointer to the EFI_FILE_PROTOCOL instance that is the file handle to write data to. See the type EFI_FILE_PROTOCOL description.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_FILE_IO_TOKEN is defined in "Related Definitions" above.

Description

The **WriteEx()** function writes the specified number of bytes to the file at the current file position. The current file position is advanced the actual number of bytes written, which is returned in *BufferSize*. Partial writes only occur when there has been a data error during the write attempt (such as “file space full”). The file is automatically grown to hold the data if required.

Direct writes to opened directories are not supported.

If non-blocking I/O is used the file pointer will be advanced based on the order that write requests were submitted.

If an error is returned from the call to **WriteEx()** and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled. If the call to **WriteEx()** succeeds then the *Event* will be signaled upon completion of the write or if an error occurs during the processing of the request. The status of the write request can be determined from the *Status* field of the *Token* once the event is signaled.

Status Codes Returned

EFI_SUCCESS	<p>Returned from the call WriteEx()</p> <p>If <i>Event</i> is NULL (blocking I/O): The data was written successfully.</p> <p>If <i>Event</i> is not NULL (asynchronous I/O): The request was successfully queued for processing. <i>Event</i> will be signaled upon completion. Returned in the token after signaling <i>Event</i> The data was written successfully.</p>
EFI_UNSUPPORTED	Writes to open directory files are not supported.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_DEVICE_ERROR	An attempt was made to write to a deleted file.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	The file or medium is write-protected.
EFI_ACCESS_DENIED	The file was opened read only.
EFI_VOLUME_FULL	The volume is full.
EFI_OUT_OF_RESOURCES	Unable to queue the request due to lack of resources.

EFI_FILE_PROTOCOL.FlushEx()

Summary

Flushes all modified data associated with a file to a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_FLUSH_EX) (
    IN EFI_FILE_PROTOCOL          *This,
    IN OUT EFI_FILE_IO_TOKEN     *Token
);
```

Parameters

This A pointer to the **EFI_FILE_PROTOCOL** instance that is the file handle to flush. See the type **EFI_FILE_PROTOCOL** description.

Token A pointer to the token associated with the transaction. Type **EFI_FILE_IO_TOKEN** is defined in "Related Definitions" above. The *BufferSize* and *Buffer* fields are not used for a *FlushEx* operation.

Description

The **FlushEx()** function flushes all modified data associated with a file to a device.

For non-blocking I/O all writes submitted before the flush request will be flushed.

If an error is returned from the call to **FlushEx()** and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled.

Status Codes Returned

EFI_SUCCESS	Returned from the call <i>FlushEx()</i> If <i>Event</i> is NULL (blocking I/O): The data was flushed successfully. If <i>Event</i> is not NULL (asynchronous I/O): The request was successfully queued for processing. Event will be signaled upon completion. Returned in the token after signaling <i>Event</i> The data was flushed successfully.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	The file or medium is write-protected.
EFI_ACCESS_DENIED	The file was opened read-only.
EFI_VOLUME_FULL	The volume is full.

Unified Extensible Firmware Interface Specification

EFI_OUT_OF_RESOURCES	Unable to queue the request due to lack of resources.
----------------------	---

EFI_FILE_PROTOCOL.SetPosition()

Summary

Sets a file's current position.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_SET_POSITION) (
    IN EFI_FILE_PROTOCOL  *This,
    IN UINT64              Position
);
```

Parameters

This

A pointer to the [EFI_FILE_PROTOCOL](#) instance that is the handle to set the requested position on. See the type [EFI_FILE_PROTOCOL](#) description.

Position

The byte position from the start of the file to set.

Description

The **SetPosition()** function sets the current file position for the handle to the position supplied. With the exception of seeking to position 0xFFFFFFFFFFFFFFFF, only absolute positioning is supported, and seeking past the end of the file is allowed (a subsequent write would grow the file). Seeking to position 0xFFFFFFFFFFFFFFFF causes the current position to be set to the end of the file.

If *This* is a directory, the only position that may be set is zero. This has the effect of starting the read process of the directory entries over.

Status Codes Returned

EFI_SUCCESS	The position was set.
EFI_UNSUPPORTED	The seek request for nonzero is not valid on open directories.
EFI_DEVICE_ERROR	An attempt was made to set the position of a deleted file.

EFI_FILE_PROTOCOL.GetPosition()

Summary

Returns a file's current position.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_GET_POSITION) (
    IN EFI_FILE_PROTOCOL  *This,
    OUT UINT64             *Position
);
```

Parameters

<i>This</i>	A pointer to the EFI_FILE_PROTOCOL instance that is the file handle to get the current position on. See the type EFI_FILE_PROTOCOL description.
<i>Position</i>	The address to return the file's current position value.

Description

The **GetPosition()** function returns the current file position for the file handle. For directories, the current file position has no meaning outside of the file system driver and as such the operation is not supported. An error is returned if *This* is a directory.

Status Codes Returned

EFI_SUCCESS	The position was returned.
EFI_UNSUPPORTED	The request is not valid on open directories.
EFI_DEVICE_ERROR	An attempt was made to get the position from a deleted file.

EFI_FILE_PROTOCOL.GetInfo()

Summary

Returns information about a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_GET_INFO) (
    IN EFI_FILE_PROTOCOL *This,
    IN EFI_GUID           *InformationType,
    IN OUT UINTN          *BufferSize,
    OUT VOID              *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_FILE_PROTOCOL instance that is the file handle the requested information is for. See the type EFI_FILE_PROTOCOL description.
<i>InformationType</i>	The type identifier for the information being requested. Type EFI_GUID is defined on page 169. See the EFI_FILE_INFO and EFI_FILE_SYSTEM_INFO descriptions for the related GUID definitions.
<i>BufferSize</i>	On input, the size of <i>Buffer</i> . On output, the amount of data returned in <i>Buffer</i> . In both cases, the size is measured in bytes.
<i>Buffer</i>	A pointer to the data buffer to return. The buffer's type is indicated by <i>InformationType</i> .

Description

The **GetInfo()** function returns information of type *InformationType* for the requested file. If the file does not support the requested information type, then **EFI_UNSUPPORTED** is returned. If the buffer is not large enough to fit the requested structure, **EFI_BUFFER_TOO_SMALL** is returned and the *BufferSize* is set to the size of buffer that is required to make the request.

The information types defined by this specification are required information types that all file systems must support.

Status Codes Returned

EFI_SUCCESS	The information was set.
EFI_UNSUPPORTED	The <i>InformationType</i> is not known.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.

Unified Extensible Firmware Interface Specification

EFI_BUFFER_TOO_SMALL	The <i>BufferSize</i> is too small to read the current directory entry. <i>BufferSize</i> has been updated with the size needed to complete the request.
----------------------	--

EFI_FILE_PROTOCOL.SetInfo()

Summary

Sets information about a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_SET_INFO) (
    IN EFI_FILE_PROTOCOL  *This,
    IN EFI_GUID           *InformationType,
    IN UINTN              BufferSize,
    IN VOID               *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_FILE_PROTOCOL instance that is the file handle the information is for. See the type EFI_FILE_PROTOCOL description.
<i>InformationType</i>	The type identifier for the information being set. Type EFI_GUID is defined in page 169. See the EFI_FILE_INFO and EFI_FILE_SYSTEM_INFO descriptions in this section for the related GUID definitions.
<i>BufferSize</i>	The size, in bytes, of <i>Buffer</i> .
<i>Buffer</i>	A pointer to the data buffer to write. The buffer's type is indicated by <i>InformationType</i> .

Description

The **SetInfo()** function sets information of type *InformationType* on the requested file. Because a read-only file can be opened only in read-only mode, an *InformationType* of [EFI_FILE_INFO_ID](#) can be used with a read-only file because this method is the only one that can be used to convert a read-only file to a read-write file. In this circumstance, only the *Attribute* field of the [EFI_FILE_INFO](#) structure may be modified. One or more calls to **SetInfo()** to change the *Attribute* field are permitted before it is closed. The file attributes will be valid the next time the file is opened with **Open()**.

An *InformationType* of [EFI_FILE_SYSTEM_INFO_ID](#) or [EFI_FILE_SYSTEM_VOLUME_LABEL_ID](#) may not be used on read-only media.

Status Codes Returned

EFI_SUCCESS	The information was set.
EFI_UNSUPPORTED	The <i>InformationType</i> is not known.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.

Unified Extensible Firmware Interface Specification

EFI_WRITE_PROTECTED	<i>InformationType</i> is EFI_FILE_INFO_ID and the media is read-only.
EFI_WRITE_PROTECTED	<i>InformationType</i> is EFI_FILE_PROTOCOL_SYSTEM_INFO_ID and the media is read only.
EFI_WRITE_PROTECTED	<i>InformationType</i> is EFI_FILE_SYSTEM_VOLUME_LABEL_ID and the media is read-only.
EFI_ACCESS_DENIED	An attempt is made to change the name of a file to a file that is already present.
EFI_ACCESS_DENIED	An attempt is being made to change the EFI_FILE_DIRECTORY Attribute .
EFI_ACCESS_DENIED	An attempt is being made to change the size of a directory.
EFI_ACCESS_DENIED	<i>InformationType</i> is EFI_FILE_INFO_ID and the file was opened read-only and an attempt is being made to modify a field other than <i>Attribute</i> .
EFI_VOLUME_FULL	The volume is full.
EFI_BAD_BUFFER_SIZE	<i>BufferSize</i> is smaller than the size of the type indicated by <i>InformationType</i> .

EFI_FILE_PROTOCOL.Flush()

Summary

Flushes all modified data associated with a file to a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_FLUSH) (
    IN EFI_FILE_PROTOCOL  *This
);
```

Parameters

This

A pointer to the [EFI_FILE_PROTOCOL](#) instance that is the file handle to flush. See the type [EFI_FILE_PROTOCOL](#) description.

Description

The **Flush()** function flushes all modified data associated with a file to a device.

Status Codes Returned

EFI_SUCCESS	The data was flushed.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	The file or medium is write-protected.
EFI_ACCESS_DENIED	The file was opened read-only.
EFI_VOLUME_FULL	The volume is full.

EFI_FILE_INFO

Summary

Provides a GUID and a data structure that can be used with [EFI_FILE_PROTOCOL.SetInfo\(\)](#) and [EFI_FILE_PROTOCOL.GetInfo\(\)](#) to set or get generic file information.

GUID

```
#define EFI_FILE_INFO_ID \
    {0x09576e92,0x6d3f,0x11d2,\
      0x8e39,0x00,0xa0,0xc9,0x69,0x72,0x3b}
```

Related Definitions

```
typedef struct {
    UINT64      Size;
    UINT64      FileSize;
    UINT64      PhysicalSize;
    EFI_TIME    CreateTime;
    EFI_TIME    LastAccessTime;
    EFI_TIME    ModificationTime;
    UINT64      Attribute;
    CHAR16      FileName[];
} EFI_FILE_INFO;

//*****
// File Attribute Bits
//*****

#define EFI_FILE_READ_ONLY          0x0000000000000001
#define EFI_FILE_HIDDEN             0x0000000000000002
#define EFI_FILE_SYSTEM             0x0000000000000004
#define EFI_FILE_RESERVED           0x0000000000000008
#define EFI_FILE_DIRECTORY          0x0000000000000010
#define EFI_FILE_ARCHIVE            0x0000000000000020
#define EFI_FILE_VALID_ATTR        0x0000000000000037
```

Parameters

<i>Size</i>	Size of the EFI_FILE_INFO structure, including the Null-terminated <i>FileName</i> string.
<i>FileSize</i>	The size of the file in bytes.
<i>PhysicalSize</i>	The amount of physical space the file consumes on the file system volume.
<i>CreateTime</i>	The time the file was created.
<i>LastAccessTime</i>	The time when the file was last accessed.
<i>ModificationTime</i>	The time when the file’s contents were last modified.
<i>Attribute</i>	The attribute bits for the file. See “Related Definitions” above.
<i>FileName</i>	The Null-terminated name of the file.

Description

The **EFI_FILE_INFO** data structure supports [GetInfo\(\)](#) and [SetInfo\(\)](#) requests. In the case of **SetInfo()**, the following additional rules apply:

- On directories, the file size is determined by the contents of the directory and cannot be changed by setting *FileSize*. On directories, *FileSize* is ignored during a **SetInfo()**.
- The *PhysicalSize* is determined by the *FileSize* and cannot be changed. This value is ignored during a **SetInfo()** request.
- The **EFI_FILE_DIRECTORY** attribute bit cannot be changed. It must match the file's actual type.
- A value of zero in *CreateTime*, *LastAccess*, or *ModificationTime* causes the fields to be ignored (and not updated).

EFI_FILE_SYSTEM_INFO

Summary

Provides a GUID and a data structure that can be used with [EFI_FILE_PROTOCOL.GetInfo\(\)](#) to get information about the system volume, and [EFI_FILE_PROTOCOL.SetInfo\(\)](#) to set the system volume's volume label.

GUID

```
#define EFI_FILE_SYSTEM_INFO_ID \
    {0x09576e93, 0x6d3f, 0x11d2, 0x8e39, 0x00, 0xa0, 0xc9, 0x69, 0x72, \
    0x3b}
```

Related Definitions

```
typedef struct {
    UINT64      Size;
    BOOLEAN     ReadOnly;
    UINT64      VolumeSize;
    UINT64      FreeSpace;
    UINT32      BlockSize;
    CHAR16      VolumeLabel[];
} EFI_FILE_SYSTEM_INFO;
```

Parameters

<i>Size</i>	Size of the EFI_FILE_SYSTEM_INFO structure, including the Null-terminated <i>VolumeLabel</i> string.
<i>ReadOnly</i>	TRUE if the volume only supports read access.
<i>VolumeSize</i>	The number of bytes managed by the file system.
<i>FreeSpace</i>	The number of available bytes for use by the file system.
<i>BlockSize</i>	The nominal block size by which files are typically grown.
<i>VolumeLabel</i>	The Null-terminated string that is the volume's label.

Description

The **EFI_FILE_SYSTEM_INFO** data structure is an information structure that can be obtained on the root directory file handle. The root directory file handle is the file handle first obtained on the

initial call to the [EFI_BOOT_SERVICES.HandleProtocol\(\)](#) function to open the file system interface. All of the fields are read-only except for *VolumeLabel*. The system volume's *VolumeLabel* can be created or modified by calling [EFI_FILE_PROTOCOL.SetInfo\(\)](#) with an updated *VolumeLabel* field.

EFI_FILE_SYSTEM_VOLUME_LABEL

Summary

Provides a GUID and a data structure that can be used with [EFI_FILE_PROTOCOL.GetInfo\(\)](#) or [EFI_FILE_PROTOCOL.SetInfo\(\)](#) to get or set information about the system's volume label.

GUID

```
#define EFI_FILE_SYSTEM_VOLUME_LABEL_ID \
  {0xdb47d7d3,0xfe81,0x11d3,0x9a35, \
   {0x00,0x90,0x27,0x3f,0xC1,0x4d}}
```

Related Definitions

```
typedef struct {
  CHAR16      VolumeLabel[];
} EFI_FILE_SYSTEM_VOLUME_LABEL;
```

Parameters

VolumeLabel The Null-terminated string that is the volume's label.

Description

The [EFI_FILE_SYSTEM_VOLUME_LABEL](#) data structure is an information structure that can be obtained on the root directory file handle. The root directory file handle is the file handle first obtained on the initial call to the [EFI_BOOT_SERVICES.HandleProtocol\(\)](#) function to open the file system interface. The system volume's *VolumeLabel* can be created or modified by calling [EFI_FILE_PROTOCOL.SetInfo\(\)](#) with an updated *VolumeLabel* field.

12.6 Tape Boot Support

12.6.1 Tape I/O Support

This section defines the Tape I/O Protocol and standard tape header format. These enable the support of booting from tape on UEFI systems. This protocol is used to abstract the tape drive operations to support applications written to this specification.

12.6.2 Tape I/O Protocol

This section defines the Tape I/O Protocol and its functions. This protocol is used to abstract the tape drive operations to support applications written to this specification.

EFI_TAPE_IO_PROTOCOL

Summary

The EFI Tape IO protocol provides services to control and access a tape device.

GUID

```
#define EFI_TAPE_IO_PROTOCOL_GUID \
    {0x1e93e633,0xd65a,0x459e, \
     {0xab,0x84,0x93,0xd9,0xec,0x26,0x6d,0x18}}
```

Protocol Interface Structure

```
typedef struct _EFI_TAPE_IO_PROTOCOL {
    EFI_TAPE_READ      TapeRead;
    EFI_TAPE_WRITE     TapeWrite;
    EFI_TAPE_REWIND    TapeRewind;
    EFI_TAPE_SPACE     TapeSpace;
    EFI_TAPE_WRITEFM   TapeWriteFM;
    EFI_TAPE_RESET     TapeReset;
} EFI_TAPE_IO_PROTOCOL;
```

Parameters

<i>TapeRead</i>	Read a block of data from the tape. See the TapeRead() description.
<i>TapeWrite</i>	Write a block of data to the tape. See the TapeWrite() description.
<i>TapeRewind</i>	Rewind the tape. See the TapeRewind() description.
<i>TapeSpace</i>	Position the tape. See the TapeSpace() description.
<i>TapeWriteFM</i>	Write filemarks to the tape. See the TapeWriteFM() description.
<i>TapeReset</i>	Reset the tape device or its parent bus. See the TapeReset() description.

Description

The **EFI_TAPE_IO_PROTOCOL** provides basic sequential operations for tape devices. These include read, write, rewind, space, write filemarks and reset functions. Per this specification, a boot application uses the services of this protocol to load the bootloader image from tape.

No provision is made for controlling or determining media density or compression settings. The protocol relies on devices to behave normally and select settings appropriate for the media loaded. No support is included for tape partition support, setmarks or other tapemarks such as End of Data. Boot tapes are expected to use normal variable or fixed block size formatting and filemarks.

EFI_TAPE_IO_PROTOCOL.TapeRead()

Summary

Reads from the tape.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TAPE_READ) (
    IN EFI_TAPE_IO_PROTOCOL    *This,
    IN OUT UINTN               *BufferSize,
    OUT VOID                   *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_TAPE_IO_PROTOCOL instance.
<i>BufferSize</i>	Size of the buffer in bytes pointed to by <i>Buffer</i> .
<i>Buffer</i>	Pointer to the buffer for data to be read into.

Description

This function will read up to *BufferSize* bytes from media into the buffer pointed to by *Buffer* using an implementation-specific timeout. *BufferSize* will be updated with the number of bytes transferred.

Each read operation for a device that operates in variable block size mode reads one media data block. Unread bytes which do not fit in the buffer will be skipped by the next read operation. The number of bytes transferred will be limited by the actual media block size. Best practice is for the buffer size to match the media data block size. When a filemark is encountered in variable block size mode the read operation will indicate that 0 bytes were transferred and the function will return an **EFI_END_OF_FILE** error condition.

In fixed block mode the buffer is expected to be a multiple of the data block size. Each read operation for a device that operates in fixed block size mode may read multiple media data blocks. The number of bytes transferred will be limited to an integral number of complete media data blocks. *BufferSize* should be evenly divisible by the device's fixed block size. When a filemark is encountered in fixed block size mode the read operation will indicate that the number of bytes transferred is less than the number of blocks that would fit in the provided buffer (possibly 0 bytes transferred) and the function will return an **EFI_END_OF_FILE** error condition.

Two consecutive filemarks are normally used to indicate the end of the last file on the media.

The value specified for *BufferSize* should correspond to the actual block size used on the media. If necessary, the value for *BufferSize* may be larger than the actual media block size.

Specifying a *BufferSize* of 0 is valid but requests the function to provide read-related status information instead of actual media data transfer. No data will be attempted to be read from the device however this operation is classified as an access for status handling. The status code returned may be used to determine if a filemark has been encountered by the last read request with a non-zero

size, and to determine if media is loaded and the device is ready for reading. A **NULL** value for *Buffer* is valid when *BufferSize* is zero.

Status Codes Returned

EFI_SUCCESS	Data was successfully transferred from the media.
EFI_END_OF_FILE	A filemark was encountered which limited the data transferred by the read operation or the head is positioned just after a filemark.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_MEDIA_CHANGED	The media in the device was changed since the last access. The transfer was aborted since the current position of the media may be incorrect.
EFI_DEVICE_ERROR	A device error occurred while attempting to transfer data from the media.
EFI_INVALID_PARAMETER	A NULL <i>Buffer</i> was specified with a non-zero <i>BufferSize</i> or the device is operating in fixed block size mode and the <i>BufferSize</i> was not a multiple of device's fixed block size
EFI_NOT_READY	The transfer failed since the device was not ready (e.g. not online). The transfer may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of transfer.
EFI_TIMEOUT	The transfer failed to complete within the timeout specified.

EFI_TAPE_IO_PROTOCOL.TapeWrite()

Summary

Write to the tape.

Prototype

```

Typedef EFI_STATUS
(EFIAPI *EFI_TAPE_WRITE) (
    IN EFI_TAPE_IO_PROTOCOL *This,
    IN UINTN *BufferSize,
    IN VOID *Buffer
);
    
```

Parameters

This A pointer to the **EFI_TAPE_IO_PROTOCOL** instance.

BufferSize Size of the buffer in bytes pointed to by *Buffer*.

Buffer Pointer to the buffer for data to be written from.

Description

This function will write *BufferSize* bytes from the buffer pointed to by *Buffer* to media using an implementation-specific timeout.

Each write operation for a device that operates in variable block size mode writes one media data block of *BufferSize* bytes.

Each write operation for a device that operates in fixed block size mode writes one or more media data blocks of the device's fixed block size. *BufferSize* must be evenly divisible by the device's fixed block size.

Although sequential devices in variable block size mode support a wide variety of block sizes, many issues may be avoided in I/O software, adapters, hardware and firmware if common block sizes are used such as: 32768, 16384, 8192, 4096, 2048, 1024, 512, and 80.

BufferSize will be updated with the number of bytes transferred.

When a write operation occurs beyond the logical end of media an **EFI_END_OF_MEDIA** error condition will occur. Normally data will be successfully written and *BufferSize* will be updated with the number of bytes transferred. Additional write operations will continue to fail in the same manner. Excessive writing beyond the logical end of media should be avoided since the physical end of media may be reached.

Specifying a *BufferSize* of 0 is valid but requests the function to provide write-related status information instead of actual media data transfer. No data will be attempted to be written to the device however this operation is classified as an access for status handling. The status code returned may be used to determine if media is loaded, writable and if the logical end of media point has been reached. A **NULL** value for *Buffer* is valid when *BufferSize* is zero.

Status Codes Returned

EFI_SUCCESS	Data was successfully transferred to the media.
-------------	---

EFI_END_OF_MEDIA	The logical end of media has been reached. Data may have been successfully transferred to the media.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_MEDIA_CHANGED	The media in the device was changed since the last access. The transfer was aborted since the current position of the media may be incorrect.
EFI_WRITE_PROTECTED	The media in the device is write-protected. The transfer was aborted since a write cannot be completed.
EFI_DEVICE_ERROR	A device error occurred while attempting to transfer data from the media.
EFI_INVALID_PARAMETER	A NULL <i>Buffer</i> was specified with a non-zero <i>BufferSize</i> or the device is operating in fixed block size mode and <i>BufferSize</i> was not a multiple of device's fixed block size.
EFI_NOT_READY	The transfer failed since the device was not ready (e.g. not online). The transfer may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of transfer.
EFI_TIMEOUT	The transfer failed to complete within the timeout specified.

EFI_TAPE_IO_PROTOCOL.TapeRewind()

Summary

Rewinds the tape.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TAPE_REWIND) (
    IN EFI_TAPE_IO_PROTOCOL    *This,
);
```

Parameters

This A pointer to the **EFI_TAPE_IO_PROTOCOL** instance.

Description

This function will rewind the media using an implementation-specific timeout. The function will check if the media was changed since the last access and reinstall the **EFI_TAPE_IO_PROTOCOL** interface for the device handle if needed.

Status Codes Returned

EFI_SUCCESS	The media was successfully repositioned.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_DEVICE_ERROR	A device error occurred while attempting to reposition the media.
EFI_NOT_READY	Repositioning the media failed since the device was not ready (e.g. not online). The transfer may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of media repositioning.
EFI_TIMEOUT	Repositioning of the media did not complete within the timeout specified.

EFI_TAPE_IO_PROTOCOL.TapeSpace()

Summary

Positions the tape.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TAPE_SPACE) (
    IN EFI_TAPE_IO_PROTOCOL    *This,
    IN INTN                    Direction,
    IN UINTN                    Type
);
```

Parameters

This A pointer to the **EFI_TAPE_IO_PROTOCOL** instance.

Direction Direction and number of data blocks or filemarks to space over on media.

Type Type of mark to space over on media.

Description

This function will position the media using an implementation-specific timeout.

A positive *Direction* value will indicate the number of data blocks or filemarks to forward space the media. A negative *Direction* value will indicate the number of data blocks or filemarks to reverse space the media.

The following *Type* marks are mandatory:

Type of Tape Mark	MarkType
BLOCK	0
FILEMARK	1

Space operations position the media past the data block or filemark. Forward space operations leave media positioned with the tape device head after the data block or filemark. Reverse space operations leave the media positioned with the tape device head before the data block or filemark.

If beginning of media is reached before a reverse space operation passes the requested number of data blocks or filemarks an **EFI_END_OF_MEDIA** error condition will occur. If end of recorded data or end of physical media is reached before a forward space operation passes the requested number of data blocks or filemarks an **EFI_END_OF_MEDIA** error condition will occur. An **EFI_END_OF_MEDIA** error condition will not occur due to spacing over data blocks or filemarks past the logical end of media point used to indicate when write operations should be limited.

Status Codes Returned

EFI_SUCCESS	The media was successfully repositioned.
-------------	--

Unified Extensible Firmware Interface Specification

EFI_END_OF_MEDIA	Beginning or end of media was reached before the indicated number of data blocks or filemarks were found.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_MEDIA_CHANGED	The media in the device was changed since the last access. Repositioning the media was aborted since the current position of the media may be incorrect.
EFI_DEVICE_ERROR	A device error occurred while attempting to reposition the media.
EFI_NOT_READY	Repositioning the media failed since the device was not ready (e.g. not online). The transfer may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of media repositioning.
EFI_TIMEOUT	Repositioning of the media did not complete within the timeout specified.

EFI_TAPE_IO_PROTOCOL.TapeWriteFM()

Summary

Writes filemarks to the media.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TAPE_WRITEFM) (
    IN EFI_TAPE_IO_PROTOCOL    *This,
    IN UINTN                    Count
);
```

Parameters

<i>This</i>	A pointer to the EFI_TAPE_IO_PROTOCOL instance.
<i>Count</i>	Number of filemarks to write to the media.

Description

This function will write filemarks to the tape using an implementation-specific timeout.

Writing filemarks beyond logical end of tape does not result in an error condition unless physical end of media is reached.

Status Codes Returned

EFI_SUCCESS	Data was successfully transferred from the media.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_MEDIA_CHANGED	The media in the device was changed since the last access. The transfer was aborted since the current position of the media may be incorrect.
EFI_DEVICE_ERROR	A device error occurred while attempting to transfer data from the media.
EFI_NOT_READY	The transfer failed since the device was not ready (e.g. not online). The transfer may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of transfer.
EFI_TIMEOUT	The transfer failed to complete within the timeout specified.

EFI_TAPE_IO_PROTOCOL.TapeReset()

Summary

Resets the tape device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TAPE_RESET) (
    IN EFI_TAPE_IO_PROTOCOL    *This,
    IN BOOLEAN                 ExtendedVerification
);
```

Parameters

This A pointer to the **EFI_TAPE_IO_PROTOCOL** instance.

ExtendedVerification Indicates whether the parent bus should also be reset.

Description

This function will reset the tape device. If *ExtendedVerification* is set to true, the function will reset the parent bus (e.g., SCSI bus). The function will check if the media was changed since the last access and reinstall the **EFI_TAPE_IO_PROTOCOL** interface for the device handle if needed. Note media needs to be loaded and device online for the reset, otherwise, **EFI_DEVICE_ERROR** is returned.

Status Codes Returned

EFI_SUCCESS	The bus and/or device were successfully reset.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_DEVICE_ERROR	A device error occurred while attempting to reset the bus and/or device.
EFI_NOT_READY	The reset failed since the device and/or bus was not ready. The reset may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of reset.
EFI_TIMEOUT	The reset did not complete within the timeout allowed.

12.6.3 Tape Header Format

The boot tape will contain a Boot Tape Header to indicate it is a valid boot tape. The Boot Tape Header must be located within the first 20 blocks on the tape. One or more tape filemarks may appear prior to the Boot Tape Header so that boot tapes may include tape label files. The Boot Tape Header must begin on a block boundary and be contained completely within a block. The Boot Tape Header will have the following format:

Table 108. Tape Header Formats

Bytes (Dec)	Value	Purpose
0-7	0x544f4f4220494645	Signature ('EFI BOOT' in ASCII)
8-11	1	Revision
12-15	1024	Tape Header Size in bytes
16-19	calculated	Tape Header CRC
20-35	{ 0x8befa29a, 0x3511, 0x4cf7, { 0xa2, 0xeb, 0x5f, 0xe3, 0x7c, 0x3b, 0xf5, 0x5b } }	EFI Boot Tape GUID (same for all EFI Boot Tapes, like EFI Disk GUID)
36-51	User Defined	EFI Boot Tape Type GUID (bootloader / OS specific, like EFI Partition Type GUID)
52-67	User Defined	EFI Boot Tape Unique GUID (unique for every EFI Boot Tape)
68-71	e.g. 2	File Number of EFI Bootloader relative to the Boot Tape Header (first file immediately after the Boot Tape Header is file number 1, ANSI labels are counted)
72-75	e.g. 0x400	EFI Bootloader Block Size in bytes
76-79	e.g. 0x20000	EFI Bootloader Total Size in bytes
80-119	e.g. HPUX 11.23	OS Version (ASCII)
120-159	e.g. Ignite-UX C.6.2.241	Application Version (ASCII)
160-169	e.g. 1993-02-28	EFI Boot Tape creation date (UTC) (yyyy-mm-dd ASCII)
170-179	e.g. 13:24:55	EFI Boot Tape creation time (UTC) (hh:mm:ss in ASCII)
180-435	e.g. testsys1 (alt e.g. testsys1.xyzcorp.com)	Computer System Name (UTF-8, ref: RFC 2044)
436-555	e.g. Primary Disaster Recovery	Boot Tape Title / Comment (UTF-8, ref: RFC 2044)
556-1023	reserved	

All numeric values will be specified in binary format. Note that all values are specified in Little Endian byte ordering.

The Boot Tape Header can also be represented as the following data structure:

```

typedef struct EFI_TAPE_HEADER {
    UINT64      Signature;
    UINT32      Revision;
    UINT32      BootDescSize;
    UINT32      BootDescCRC;
    EFI_GUID    TapeGUID;
    EFI_GUID    TapeType;
    EFI_GUID    TapeUnique;
    UINT32      BLLocation;
    UINT32      BLBlocksize;
    UINT32      BLFilesize;
    CHAR8       OSVersion[40];
    CHAR8       AppVersion[40];
    CHAR8       CreationDate[10];
    CHAR8       CreationTime[10];
    CHAR8       SystemName[256];    // UTF-8
    CHAR8       TapeTitle[120];    // UTF-8
    CHAR8       pad[468];          // pad to 1024
} EFI_TAPE_HEADER;

```

12.7 Disk I/O Protocol

This section defines the Disk I/O protocol. This protocol is used to abstract the block accesses of the Block I/O protocol to a more general offset-length protocol. The firmware is responsible for adding this protocol to any Block I/O interface that appears in the system that does not already have a Disk I/O protocol. File systems and other disk access code utilize the Disk I/O protocol.

EFI_DISK_IO_PROTOCOL

Summary

This protocol is used to abstract Block I/O interfaces.

GUID

```
#define EFI_DISK_IO_PROTOCOL_GUID \
    {0xCE345171,0xBA0B,0x11d2,\
     0x8e,0x4F,0x00,0xa0,0xc9,0x69,0x72,0x3b}
```

Revision Number

```
#define EFI_DISK_IO_PROTOCOL_REVISION 0x00010000
```

Protocol Interface Structure

```
typedef struct _EFI_DISK_IO_PROTOCOL {
    UINT64      Revision;
    EFI_DISK_READ  ReadDisk;
    EFI_DISK_WRITE WriteDisk;
} EFI_DISK_IO_PROTOCOL;
```

Parameters

<i>Revision</i>	The revision to which the disk I/O interface adheres. All future revisions must be backwards compatible. If a future version is not backwards compatible, it is not the same GUID.
<i>ReadDisk</i>	Reads data from the disk. See the ReadDisk() function description.
<i>WriteDisk</i>	Writes data to the disk. See the WriteDisk() function description.

Description

The **EFI_DISK_IO_PROTOCOL** is used to control block I/O interfaces.

The disk I/O functions allow I/O operations that need not be on the underlying device's block boundaries or alignment requirements. This is done by copying the data to/from internal buffers as needed to provide the proper requests to the block I/O device. Outstanding write buffer data is flushed by using the [FlushBlocks\(\)](#) function of the [EFI_BLOCK_IO_PROTOCOL](#) on the device handle.

The firmware automatically adds an **EFI_DISK_IO_PROTOCOL** interface to any **EFI_BLOCK_IO_PROTOCOL** interface that is produced. It also adds file system, or logical block I/O, interfaces to any [EFI_DISK_IO_PROTOCOL](#) interface that contains any recognized file system or logical block I/O devices. The firmware must automatically support the following required formats:

- The EFI FAT12, FAT16, and FAT32 file system type.
- The legacy master boot record partition block. (The presence of this on any block I/O device is optional, but if it is present the firmware is responsible for allocating a logical device for each partition).
- The extended partition record partition block.
- The El Torito logical block devices.

EFI_DISK_IO_PROTOCOL.ReadDisk()

Summary

Reads a specified number of bytes from a device.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_DISK_READ) (
    IN EFI_DISK_IO_PROTOCOL  *This,
    IN UINT32                 MediaId,
    IN UINT64                 Offset,
    IN UINTN                  BufferSize,
    OUT VOID                  *Buffer
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_DISK_IO_PROTOCOL is defined in the EFI_DISK_IO_PROTOCOL description.
<i>MediaId</i>	ID of the medium to be read.
<i>Offset</i>	The starting byte offset on the logical block I/O device to read from.
<i>BufferSize</i>	The size in bytes of <i>Buffer</i> . The number of bytes to read from the device.
<i>Buffer</i>	A pointer to the destination buffer for the data. The caller is responsible for either having implicit or explicit ownership of the buffer.

Description

The **ReadDisk()** function reads the number of bytes specified by *BufferSize* from the device. All the bytes are read, or an error is returned. If there is no medium in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID of the medium currently in the device, the function returns **EFI_MEDIA_CHANGED**.

Status Codes Returned

EFI_SUCCESS	The data was read correctly from the device.
EFI_DEVICE_ERROR	The device reported an error while performing the read operation.
EFI_NO_MEDIA	There is no medium in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current medium.
EFI_INVALID_PARAMETER	The read request contains device addresses that are not valid for the device.

EFI_DISK_IO_PROTOCOL.WriteDisk()

Summary

Writes a specified number of bytes to a device.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_DISK_WRITE) (
    IN EFI_DISK_IO_PROTOCOL *This,
    IN UINT32                MediaId,
    IN UINT64                Offset,
    IN UINTN                 BufferSize,
    IN VOID                  *Buffer
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_DISK_IO_PROTOCOL is defined in the EFI_DISK_IO_PROTOCOL protocol description.
<i>MediaId</i>	ID of the medium to be written.
<i>Offset</i>	The starting byte offset on the logical block I/O device to write.
<i>BufferSize</i>	The size in bytes of <i>Buffer</i> . The number of bytes to write to the device.
<i>Buffer</i>	A pointer to the buffer containing the data to be written.

Description

The **WriteDisk()** function writes the number of bytes specified by *BufferSize* to the device. All bytes are written, or an error is returned. If there is no medium in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID of the medium currently in the device, the function returns **EFI_MEDIA_CHANGED**.

Status Codes Returned

EFI_SUCCESS	The data was written correctly to the device.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no medium in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current medium.
EFI_DEVICE_ERROR	The device reported an error while performing the write operation.
EFI_INVALID_PARAMETER	The write request contains device addresses that are not valid for the device.

12.8 Disk I/O 2 Protocol

The Disk I/O 2 protocol defines an extension to the Disk I/O protocol to enable non-blocking / asynchronous byte-oriented disk operation.

EFI_DISK_IO2_PROTOCOL

Summary

This protocol is used to abstract Block I/O interfaces in a non-blocking manner.

GUID

```
#define EFI_DISK_IO2_PROTOCOL_GUID \
  { 0x151c8eae, 0x7f2c, 0x472c, \
    {0x9e, 0x54, 0x98, 0x28, 0x19, 0x4f, 0x6a, 0x88 } }
```

Revision Number

```
#define EFI_DISK_IO2_PROTOCOL_REVISION 0x00020000
```

Protocol Interface Structure

```
typedef struct _EFI_DISK_IO2_PROTOCOL {
  UINT64          Revision;
  EFI_DISK_CANCEL_EX  Cancel;
  EFI_DISK_READ_EX   ReadDiskEx;
  EFI_DISK_WRITE_EX  WriteDiskEx;
  EFI_DISK_FLUSH_EX  FlushDiskEx;
} EFI_DISK_IO2_PROTOCOL;
```

Parameters

<i>Revision</i>	The revision to which the disk I/O interface adheres. All future revisions must be backwards compatible.
<i>Cancel</i>	Terminate outstanding requests. See the Cancel() function description.
<i>ReadDiskEx</i>	Reads data from the disk. See the ReadDiskEx() function description.
<i>WriteDiskEx</i>	Writes data to the disk. See the WriteDiskEx() function description.
<i>FlushDiskEx</i>	Flushes all modified data to the physical device. See the FlushDiskEx() function description.

Description

The **EFI_DISK_IO2_PROTOCOL** is used to control block I/O interfaces.

The disk I/O functions allow I/O operations that need not be on the underlying device's block boundaries or alignment requirements. This is done by copying the data to/from internal buffers as needed to provide the proper requests to the block I/O device. Outstanding write buffer data is

flushed by using the **FlushBlocksEx()** function of the **EFI_BLOCK_IO2_PROTOCOL** on the device handle.

The firmware automatically adds an **EFI_DISK_IO2_PROTOCOL** interface to any **EFI_BLOCK_IO2_PROTOCOL** interface that is produced. It also adds file system, or logical block I/O, interfaces to any **EFI_DISK_IO2_PROTOCOL** interface that contains any recognized file system or logical block I/O devices.

Implementations must account for cases where there is pending queued asynchronous I/O when a call is received on a blocking protocol interface. In these cases the pending I/O will be processed and completed before the blocking function is executed so that operation are carried out in the order they were requested.

EFI_DISK_IO2_PROTOCOL.Cancel()

Summary

Terminate outstanding asynchronous requests to a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISK_CANCEL_EX) (
    IN EFI_DISK_IO2_PROTOCOL  *This
);
```

Parameters

This Indicates a pointer to the calling context. Type **EFI_DISK_IO2_PROTOCOL** is defined in the **EFI_DISK_IO2_PROTOCOL** description.

Description

The **Cancel()** function will terminate any in-flight non-blocking I/O requests by signaling the **EFI_DISK_IO2_TOKEN** Event and with *TransactionStatus* set to **EFI_ABORTED**. After the **Cancel()** function returns it is safe to free any *Token* or *Buffer* data structures that were allocated as part of the non-blocking I/O operation.

Status Codes Returned

EFI_SUCCESS	All outstanding requests were successfully terminated.
EFI_DEVICE_ERROR	The device reported an error while performing the cancel operation.

EFI_DISK_IO2_PROTOCOL.ReadDiskEx()

Summary

Reads a specified number of bytes from a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISK_READ_EX) (
    IN EFI_DISK_IO2_PROTOCOL *This,
    IN UINT32                 MediaId,
    IN UINT64                 Offset,
    IN OUT EFI_DISK_IO2_TOKEN *Token,
    IN UINTN                  BufferSize,
    OUT VOID                  *Buffer
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_DISK_IO2_PROTOCOL is defined in the EFI_DISK_IO2_PROTOCOL description.
<i>MediaId</i>	ID of the medium to be read.
<i>Offset</i>	The starting byte offset on the logical block I/O device to read from.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_DISK_IO2_TOKEN is defined in "Related Definitions" below. If this field is NULL, synchronous/blocking IO is performed.
<i>BufferSize</i>	The size in bytes of <i>Buffer</i> . The number of bytes to read from the device.
<i>Buffer</i>	A pointer to the destination buffer for the data. The caller is responsible either having implicit or explicit ownership of the buffer.

Description

The **ReadDiskEx()** function reads the number of bytes specified by *BufferSize* from the device. All the bytes are read, or an error is returned. If there is no medium in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID of the medium currently in the device, the function returns **EFI_MEDIA_CHANGED**.

If an error is returned from the call to **ReadDiskEx()** and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled. If the call to **ReadDiskEx()** succeeds then the *Event* will be signaled upon completion of the read or if an error occurs during the processing of the request. The status of the read request can be determined from the *Status* field of the *Token* once the event is signaled.

Related Definitions

```
typedef struct {
    EFI_EVENT      Event;
    EFI_STATUS     TransactionStatus;
} EFI_DISK_IO2_TOKEN;
```

Event If *Event* is NULL, then blocking I/O is performed. If *Event* is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the I/O request is completed. The caller must be prepared to handle the case where the callback associated with *Event* occurs before the original asynchronous I/O request call returns.

TransactionStatus Defines whether or not the signaled event encountered an error.

Status Codes Returned

EFI_SUCCESS	Returned from the call <code>ReadDiskEx()</code> If <i>Event</i> is NULL (blocking I/O): The data was read correctly from the device. If <i>Event</i> is not NULL (asynchronous I/O): The request was successfully queued for processing. Event will be signaled upon completion. Returned in the token after signaling <i>Event</i> The data was read correctly from the device.
EFI_DEVICE_ERROR	The device reported an error while performing the read operation.
EFI_NO_MEDIA	There is no medium in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current medium.
EFI_INVALID_PARAMETER	The read request contains device addresses that are not valid for the device.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

EFI_DISK_IO2_PROTOCOL.WriteDiskEx()

Summary

Writes a specified number of bytes to a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISK_WRITE_EX) (
    IN EFI_DISK_IO2_PROTOCOL  *This,
    IN UINT32                  MediaId,
    IN UINT64                  Offset,
    IN OUT EFI_DISK_IO2_TOKEN *Token,
    IN UINTN                   BufferSize,
    IN VOID                    *Buffer
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_DISK_IO2_PROTOCOL is defined in the EFI_DISK_IO2_PROTOCOL description.
<i>MediaId</i>	ID of the medium to be written.
<i>Offset</i>	The starting byte offset on the logical block I/O device to write to.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_DISK_IO2_TOKEN is defined in "Related Definitions" below. If this field is NULL, synchronous/blocking IO is performed.
<i>BufferSize</i>	The size in bytes of <i>Buffer</i> . The number of bytes to write to the device.
<i>Buffer</i>	A pointer to the source buffer for the data. The caller is responsible.

Description

The **WriteDiskEx()** function writes the number of bytes specified by *BufferSize* to the device. All bytes are written, or an error is returned. If there is no medium in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID of the medium currently in the device, the function returns **EFI_MEDIA_CHANGED**.

If an error is returned from the call to **WriteDiskEx()** and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled. If the call to **WriteDiskEx()** succeeds then the *Event* will be signaled upon completion of the write or if an error occurs during the processing of the request. The status of the write request can be determined from the *Status* field of the *Token* once the event is signaled.

Status Codes Returned

EFI_SUCCESS	<p>Returned from the call WriteDiskEx()</p> <p>If <i>Event</i> is NULL (blocking I/O):</p> <ul style="list-style-type: none"> The data was written correctly to the device. <p>If <i>Event</i> is not NULL (asynchronous I/O):</p> <ul style="list-style-type: none"> The request was successfully queued for processing. <i>Event</i> will be signaled upon completion. <p>Returned in the token after signaling <i>Event</i></p> <ul style="list-style-type: none"> The data was written correctly to the device.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_DEVICE_ERROR	The device reported an error while performing the write operation.
EFI_NO_MEDIA	There is no medium in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current medium.
EFI_INVALID_PARAMETER	The read request contains device addresses that are not valid for the device.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

EFI_DISK_IO2_PROTOCOL.FlushDiskEx()

Summary

Flushes all modified data to the physical device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISK_FLUSH_EX) (
    IN EFI_DISK_IO2_PROTOCOL  *This,
    IN OUT EFI_DISK_IO2_TOKEN *Token
);
```

Parameters

This

Indicates a pointer to the calling context. Type **EFI_DISK_IO2_PROTOCOL** is defined in the **EFI_DISK_IO2_PROTOCOL** description.

Token

A pointer to the token associated with the transaction. Type **EFI_DISK_IO2_TOKEN** is defined in "Related Definitions" below. If this field is NULL, synchronous/blocking IO is performed.

Description

The **FlushDiskEx()** function flushes all modified data to the physical device. If an error is returned from the call to **FlushDiskEx()** and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled. If the call to **FlushDiskEx()** succeeds then the *Event* will be signaled upon completion of the flush or if an error occurs during the processing of the request. The status of the flush request can be determined from the *Status* field of the *Token* once the event is signaled.

Status Codes Returned

EFI_SUCCESS	<p>Returned from the call <i>FlushDiskEx()</i></p> <p>If <i>Event</i> is NULL (blocking I/O):</p> <ul style="list-style-type: none"> The data was flushed successfully to the device. <p>If <i>Event</i> is not NULL (asynchronous I/O):</p> <ul style="list-style-type: none"> The request was successfully queued for processing. <i>Event</i> will be signaled upon completion. <p>Returned in the token after signaling <i>Event</i> The data was flushed successfully to the device.</p>
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_DEVICE_ERROR	The device reported an error while performing the flush operation.
EFI_NO_MEDIA	There is no medium in the device.
EFI_MEDIA_CHANGED	The medium in the device has changed since the last access.
EFI_INVALID_PARAMETER	Token is NULL.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

12.9 Block I/O Protocol

This section defines the Block I/O protocol. This protocol is used to abstract mass storage devices to allow code running in the EFI boot services environment to access them without specific knowledge of the type of device or controller that manages the device. Functions are defined to read and write data at a block level from mass storage devices as well as to manage such devices in the EFI boot services environment.

EFI_BLOCK_IO_PROTOCOL

Summary

This protocol provides control over block devices.

GUID

```
#define EFI_BLOCK_IO_PROTOCOL_GUID \
    {0x964e5b21,0x6459,0x11d2,\
     {0x8e,0x39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Revision Number

```
#define EFI_BLOCK_IO_PROTOCOL_REVISION2    0x00020001
#define EFI_BLOCK_IO_PROTOCOL_REVISION3    ((2<<16) | (31))
```

Protocol Interface Structure

```
typedef struct _EFI_BLOCK_IO_PROTOCOL {
    UINT64                Revision;
    EFI_BLOCK_IO_MEDIA    *Media;
    EFI_BLOCK_RESET       Reset;
    EFI_BLOCK_READ         ReadBlocks;
    EFI_BLOCK_WRITE       WriteBlocks;
    EFI_BLOCK_FLUSH       FlushBlocks;
} EFI_BLOCK_IO_PROTOCOL;
```

Parameters

<i>Revision</i>	The revision to which the block IO interface adheres. All future revisions must be backwards compatible. If a future version is not backwards compatible it is not the same GUID.
<i>Media</i>	A pointer to the EFI_BLOCK_IO_MEDIA data for this device. Type EFI_BLOCK_IO_MEDIA is defined in “Related Definitions” below.
<i>Reset</i>	Resets the block device hardware. See the Reset() function description.
<i>ReadBlocks</i>	Reads the requested number of blocks from the device. See the ReadBlocks() function description.
<i>WriteBlocks</i>	Writes the requested number of blocks to the device. See the WriteBlocks() function description.
<i>FlushBlocks</i>	Flushes any cache blocks. This function is optional and only needs to be supported on block devices that cache writes. See the FlushBlocks() function description.

Related Definitions

```

//*****
// EFI_BLOCK_IO_MEDIA
//*****

typedef struct {
    UINT32      MediaId;
    BOOLEAN     RemovableMedia;
    BOOLEAN     MediaPresent;
    BOOLEAN     LogicalPartition;
    BOOLEAN     ReadOnly;
    BOOLEAN     WriteCaching;
    UINT32      BlockSize;
    UINT32      IoAlign;
    EFI_LBA     LastBlock;

    EFI_LBA     LowestAlignedLba; //added in Revision 2
    UINT32      LogicalBlocksPerPhysicalBlock;
//added in Revision 2
    UINT32      OptimalTransferLengthGranularity;
// added in Revision 3
} EFI_BLOCK_IO_MEDIA;

//*****
// EFI_LBA
//*****
typedef UINT64      EFI_LBA;
    
```

The following data values in **EFI_BLOCK_IO_MEDIA** are read-only and are updated by the code that produces the **EFI_BLOCK_IO_PROTOCOL** functions:

<i>MediaId</i>	The current media ID. If the media changes, this value is changed.
<i>RemovableMedia</i>	TRUE if the media is removable; otherwise, FALSE .
<i>MediaPresent</i>	TRUE if there is a media currently present in the device; otherwise, FALSE . This field shows the media present status as of the most recent ReadBlocks() or WriteBlocks() call.
<i>LogicalPartition</i>	TRUE if the EFI_BLOCK_IO_PROTOCOL was produced to abstract partition structures on the disk. FALSE if the BLOCK_IO protocol was produced to abstract the logical blocks on a hardware device.
<i>ReadOnly</i>	TRUE if the media is marked read-only otherwise, FALSE . This field shows the read-only status as of the most recent WriteBlocks() call.
<i>WriteCaching</i>	TRUE if the WriteBlocks() function caches write data.
<i>BlockSize</i>	The intrinsic block size of the device. If the media changes, then this field is updated. Returns the number of bytes per logical

block. For ATA devices, this is reported in IDENTIFY DEVICE data words 117-118 (i.e., Words per Logical Sector) (see ATA8-ACS). For SCSI devices, this is reported in the READ CAPACITY (16) parameter data Logical Block Length In Bytes field (see SBC-3).

<i>IoAlign</i>	Supplies the alignment requirement for any buffer used in a data transfer. <i>IoAlign</i> values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, <i>IoAlign</i> must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by <i>IoAlign</i> with no remainder.
<i>LastBlock</i>	The last LBA on the device. If the media changes, then this field is updated. For ATA devices, this is reported in IDENTIFY DEVICE data words 60-61 (i.e., Total number of user addressable logical sectors) (see ATA8-ACS) minus one. For SCSI devices, this is reported in the READ CAPACITY (16) parameter data Returned Logical Block Address field (see SBC-3) minus one.
<i>LowestAlignedLba</i>	Only present if EFI_BLOCK_IO_PROTOCOL.Revision is greater than or equal to EFI_BLOCK_IO_PROTOCOL_REVISION2 . Returns the first LBA that is aligned to a physical block boundary (see Section 5.3.1). Note that this field follows the SCSI definition, not the ATA definition. If <i>LogicalPartition</i> is TRUE this value will be zero.
<i>LogicalBlocksPerPhysicalBlock</i>	Only present if EFI_BLOCK_IO_PROTOCOL.Revision is greater than or equal to EFI_BLOCK_IO_PROTOCOL_REVISION2 . Returns the number of logical blocks per physical block (see Section 5.3.1). Unlike the ATA and SCSI fields that provide the information for this field, this field does not contain an exponential value. A value of 0 means there is either one logical block per physical block, or there are more than one physical block per logical block. If <i>LogicalPartition</i> is TRUE this value will be zero.
<i>OptimalTransferLengthGranularity</i>	Only present if EFI_BLOCK_IO_PROTOCOL.Revision is greater than or equal to EFI_BLOCK_IO_PROTOCOL_REVISION3 . Returns the optimal transfer length granularity as a number of logical blocks (see Section 5.3.1). A value of 0 means there is no reported optimal transfer length granularity. If <i>LogicalPartition</i> is TRUE this value will be zero.

Description

The *LogicalPartition* is **TRUE** if the device handle is for a partition. For media that have only one partition, the value will always be **TRUE**. For media that have multiple partitions, this

value is **FALSE** for the handle that accesses the entire device. The firmware is responsible for adding device handles for each partition on such media.

The firmware is responsible for adding an [EFI_DISK_IO_PROTOCOL](#) interface to every [EFI_BLOCK_IO_PROTOCOL](#) interface in the system. The **EFI_DISK_IO_PROTOCOL** interface allows byte-level access to devices.

EFI_BLOCK_IO_PROTOCOL.Reset()

Summary

Resets the block device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_RESET) (
    IN EFI_BLOCK_IO_PROTOCOL  *This,
    IN BOOLEAN                 ExtendedVerification
);
```

Parameters

This Indicates a pointer to the calling context. Type **EFI_BLOCK_IO_PROTOCOL** is defined in the [EFI_BLOCK_IO_PROTOCOL](#) description.

ExtendedVerification Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The **Reset()** function resets the block device hardware.

As part of the initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the *ExtendedVerification* flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The block device was reset.
EFI_DEVICE_ERROR	The block device is not functioning correctly and could not be reset.

EFI_BLOCK_IO_PROTOCOL.ReadBlocks()

Summary

Reads the requested number of blocks from the device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_READ) (
    IN EFI_BLOCK_IO_PROTOCOL  *This,
    IN UINT32                  MediaId,
    IN EFI_LBA                 LBA,
    IN UINTN                   BufferSize,
    OUT VOID                   *Buffer
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_BLOCK_IO_PROTOCOL is defined in the EFI_BLOCK_IO_PROTOCOL description.
<i>MediaId</i>	The media ID that the read request is for.
<i>LBA</i>	The starting logical block address to read from on the device. Type EFI_LBA is defined in the EFI_BLOCK_IO_PROTOCOL description.
<i>BufferSize</i>	The size of the <i>Buffer</i> in bytes. This must be a multiple of the intrinsic block size of the device.
<i>Buffer</i>	A pointer to the destination buffer for the data. The caller is responsible for either having implicit or explicit ownership of the buffer.

Description

The **ReadBlocks ()** function reads the requested number of blocks from the device. All the blocks are read, or an error is returned.

If there is no media in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID for the current media in the device, the function returns **EFI_MEDIA_CHANGED**. The function must return **EFI_NO_MEDIA** or **EFI_MEDIA_CHANGED** even if *LBA*, *BufferSize*, or *Buffer* are invalid so the caller can probe for changes in media state.

Status Codes Returned

EFI_SUCCESS	The data was read correctly from the device.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the read operation.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.

EFI_BAD_BUFFER_SIZE	The <i>BufferSize</i> parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	The read request contains LBAs that are not valid, or the buffer is not on proper alignment.

EFI_BLOCK_IO_PROTOCOL.WriteBlocks()

Summary

Writes a specified number of blocks to the device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_WRITE) (
    IN EFI_BLOCK_IO_PROTOCOL  *This,
    IN UINT32                  MediaId,
    IN EFI_LBA                 LBA,
    IN UINTN                   BufferSize,
    IN VOID                    *Buffer
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type is defined in the EFI_BLOCK_IO_PROTOCOL description.
<i>MediaId</i>	The media ID that the write request is for.
<i>LBA</i>	The starting logical block address to be written. The caller is responsible for writing to only legitimate locations. Type EFI_LBA is defined in the EFI_BLOCK_IO_PROTOCOL description.
<i>BufferSize</i>	The size in bytes of <i>Buffer</i> . This must be a multiple of the intrinsic block size of the device.
<i>Buffer</i>	A pointer to the source buffer for the data.

Description

The **WriteBlocks()** function writes the requested number of blocks to the device. All blocks are written, or an error is returned.

If there is no media in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID for the current media in the device, the function returns **EFI_MEDIA_CHANGED**. The function must return **EFI_NO_MEDIA** or **EFI_MEDIA_CHANGED** even if *LBA*, *BufferSize*, or *Buffer* are invalid so the caller can probe for changes in media state.

Status Codes Returned

EFI_SUCCESS	The data were written correctly to the device.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the write operation.

EFI_BAD_BUFFER_SIZE	The <i>BufferSize</i> parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	The write request contains LBAs that are not valid, or the buffer is not on proper alignment.

EFI_BLOCK_IO_PROTOCOL.FlushBlocks()

Summary

Flushes all modified data to a physical block device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_FLUSH) (
    IN EFI_BLOCK_IO_PROTOCOL    *This
);
```

Parameters

This

Indicates a pointer to the calling context. Type **EFI_BLOCK_IO_PROTOCOL** is defined in the [EFI_BLOCK_IO_PROTOCOL](#) protocol description.

Description

The **FlushBlocks()** function flushes all modified data to the physical block device.

All data written to the device prior to the flush must be physically written before returning **EFI_SUCCESS** from this function. This would include any cached data the driver may have cached, and cached data the device may have cached. A flush may cause a read request following the flush to force a device access.

Status Codes Returned

EFI_SUCCESS	All outstanding data were written correctly to the device.
EFI_DEVICE_ERROR	The device reported an error while attempting to write data.
EFI_NO_MEDIA	There is no media in the device.

12.10 Block I/O 2 Protocol

The Block I/O 2 protocol defines an extension to the Block I/O protocol which enables the ability to read and write data at a block level in a non-blocking manner.

EFI_BLOCK_IO2_PROTOCOL

Summary

This protocol provides control over block devices.

GUID

```
#define EFI_BLOCK_IO2_PROTOCOL_GUID \
    {0xa77b2472, 0xe282, 0x4e9f, \
     {0xa2, 0x45, 0xc2, 0xc0, 0xe2, 0x7b, 0xbc, 0xc1}}
```

Protocol Interface Structure

```
typedef struct _EFI_BLOCK_IO2_PROTOCOL {
    EFI_BLOCK_IO_MEDIA      *Media;
    EFI_BLOCK_RESET_EX      Reset;
    EFI_BLOCK_READ_EX       ReadBlocksEx;
    EFI_BLOCK_WRITE_EX      WriteBlocksEx;
    EFI_BLOCK_FLUSH_EX      FlushBlocksEx;
} EFI_BLOCK_IO2_PROTOCOL;
```

Parameters

<i>Media</i>	A pointer to the EFI_BLOCK_IO_MEDIA data for this device. Type EFI_BLOCK_IO_MEDIA is defined in the EFI_BLOCK_IO_PROTOCOL section.
<i>Reset</i>	Resets the block device hardware. See the Reset() function description following below.
<i>ReadBlocksEx</i>	Reads the requested number of blocks from the device. See the EFI_BLOCK_IO2_PROTOCOL.ReadBlocksEx() function description.
<i>WriteBlocksEx</i>	Writes the requested number of blocks to the device. See the WriteBlocksEx() function description.
<i>FlushBlocksEx</i>	Flushes any cache blocks. This function is optional and only needs to be supported on block devices that cache writes. See the FlushBlocksEx() function description.

EFI_BLOCK_IO2_PROTOCOL.Reset()

Summary

Resets the block device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_RESET_EX) (
    IN EFI_BLOCK_IO2_PROTOCOL *This,
    IN BOOLEAN ExtendedVerification
);
```

Parameters

This Indicates a pointer to the calling context. Type **EFI_BLOCK_IO2_PROTOCOL** is defined in the **EFI_BLOCK_IO2_PROTOCOL** description.

ExtendedVerification Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The **Reset()** function resets the block device hardware.

As part of the initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the *ExtendedVerification* flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

The **Reset()** function will terminate any in-flight non-blocking I/O requests by signaling an **EFI_ABORTED** in the *TransactionStatus* member of the **EFI_BLOCK_IO2_TOKEN** for the non-blocking I/O. After the **Reset()** function returns it is safe to free any *Token* or *Buffer* data structures that were allocated to initiate the non-blocking I/O requests that were in-flight for this device.

Status Codes Returned

EFI_SUCCESS	The block device was reset.
EFI_DEVICE_ERROR	The block device is not functioning correctly and could not be reset.

EFI_BLOCK_IO2_PROTOCOL.ReadBlocksEx()

Summary

Reads the requested number of blocks from the device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_READ_EX) (
    IN EFI_BLOCK_IO2_PROTOCOL      *This,
    IN UINT32                      MediaId,
    IN EFI_LBA                    LBA,
    IN OUT EFI_BLOCK_IO2_TOKEN    *Token,
    IN UINTN                      BufferSize,
    OUT VOID                      *Buffer
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_BLOCK_IO2_PROTOCOL is defined in the EFI_BLOCK_IO2_PROTOCOL description.
<i>MediaId</i>	The media ID that the read request is for.
<i>LBA</i>	The starting logical block address to read from on the device. Type EFI_LBA is defined in the EFI_BLOCK_IO_PROTOCOL description.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_BLOCK_IO2_TOKEN is defined in "Related Definitions" below.
<i>BufferSize</i>	The size of the <i>Buffer</i> in bytes. This must be a multiple of the intrinsic block size of the device.
<i>Buffer</i>	A pointer to the destination buffer for the data. The caller is responsible for either having implicit or explicit ownership of the buffer.

Description

The **ReadBlocksEx()** function reads the requested number of blocks from the device. All the blocks are read, or an error is returned.

If there is no media in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID for the current media in the device, the function returns **EFI_MEDIA_CHANGED**. The function must return **EFI_NO_MEDIA** or **EFI_MEDIA_CHANGED** even if *LBA*, *BufferSize*, or *Buffer* are invalid so the caller can probe for changes in media state.

If **EFI_DEVICE_ERROR**, **EFI_NO_MEDIA**, or **EFI_MEDIA_CHANGED** is returned and non-blocking I/O is being used, the *Event* associated with this request will not be signaled.

Related Definitions

```
typedef struct {
    EFI_EVENT          Event;
    EFI_STATUS        TransactionStatus;
} EFI_BLOCK_IO2_TOKEN;
```

Event If *Event* is NULL, then blocking I/O is performed. If *Event* is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the read request is completed.

TransactionStatus Defines whether the signaled event encountered an error.

Status Codes Returned

EFI_SUCCESS	The read request was queued if Token-> Event is not NULL. The data was read correctly from the device if theToken-> Event is NULL.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the read operation.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.
EFI_BAD_BUFFER_SIZE	The <i>BufferSize</i> parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	The read request contains LBAs that are not valid, or the buffer is not on proper alignment.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

EFI_BLOCK_IO2_PROTOCOL.WriteBlocksEx()

Summary

Writes a specified number of blocks to the device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_WRITE_EX) (
    IN EFI_BLOCK_IO2_PROTOCOL      *This,
    IN UINT32                       MediaId,
    IN EFI_LBA                       LBA,
    IN OUT EFI_BLOCK_IO2_TOKEN      *Token,
    IN UINTN                         BufferSize,
    IN VOID                          *Buffer
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_BLOCK_IO2_PROTOCOL is defined in the EFI_BLOCK_IO2_PROTOCOL description.
<i>MediaId</i>	The media ID that the write request is for.
<i>LBA</i>	The starting logical block address to be written. The caller is responsible for writing to only legitimate locations. Type EFI_LBA is defined in the EFI_BLOCK_IO2_PROTOCOL description.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_BLOCK_IO2_TOKEN is defined in EFI_BLOCK_IO2_PROTOCOL.ReadBlocksEx(,) "Related Definitions".
<i>BufferSize</i>	The size in bytes of <i>Buffer</i> . This must be a multiple of the intrinsic block size of the device.
<i>Buffer</i>	A pointer to the source buffer for the data.

Description

The **WriteBlocksEx()** function writes the requested number of blocks to the device. All blocks are written, or an error is returned.

If there is no media in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID for the current media in the device, the function returns **EFI_MEDIA_CHANGED**. The function must return **EFI_NO_MEDIA** or **EFI_MEDIA_CHANGED** even if *LBA*, *BufferSize*, or *Buffer* are invalid so the caller can probe for changes in media state.

If **EFI_DEVICE_ERROR**, **EFI_NO_MEDIA**, **EFI_WRITE_PROTECTED** or **EFI_MEDIA_CHANGED** is returned and non-blocking I/O is being used, the *Event* associated with this request will not be signaled.

Related Definitions

```
typedef struct {
    EFI_EVENT          Event;
    EFI_STATUS        TransactionStatus;
} EFI_BLOCK_IO2_TOKEN;
```

Event If *Event* is NULL, then blocking I/O is performed. If *Event* is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the write request is completed.

TransactionStatus Defines whether the signaled event encountered an error.

Status Codes Returned

EFI_SUCCESS	The write request was queued if Event is not NULL. The data was written correctly to the device if the Event is NULL.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the write operation.
EFI_BAD_BUFFER_SIZE	The <i>BufferSize</i> parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	The write request contains LBAs that are not valid, or the buffer is not on proper alignment.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

EFI_BLOCK_IO2_PROTOCOL.FlushBlocksEx()

Summary

Flushes all modified data to a physical block device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_FLUSH_EX) (
    IN EFI_BLOCK_IO2_PROTOCOL      *This,
    IN OUT EFI_BLOCK_IO2_TOKEN     *Token,
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_BLOCK_IO2_PROTOCOL is defined in the EFI_BLOCK_IO2_PROTOCOL protocol description.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_BLOCK_IO2_TOKEN is defined in EFI_BLOCK_IO2_PROTOCOL.ReadBlocksEx() , "Related Definitions".

Related Definitions

```
typedef struct {
    EFI_EVENT                      Event;
    EFI_STATUS                     TransactionStatus;
} EFI_BLOCK_IO2_TOKEN;
```

Event If *Event* is NULL, then blocking I/O is performed. If *Event* is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the flush request is completed.

TransactionStatus Defines whether the signaled event encountered an error.

Description

The **FlushBlocksEx()** function flushes all modified data to the physical block device.

All data written to the device prior to the flush must be physically written before returning **EFI_SUCCESS** from this function. This would include any cached data the driver may have cached, and cached data the device may have cached. A flush may cause a read request following the flush to force a device access.

If **EFI_DEVICE_ERROR**, **EFI_NO_MEDIA**, **EFI_WRITE_PROTECTED** or **EFI_MEDIA_CHANGED** is returned and non-blocking I/O is being used, the *Event* associated with this request will not be signaled.

Status Codes Returned

EFI_SUCCESS	The flush request was queued if Event is not NULL. All outstanding data was written correctly to the device if the Event is NULL.
EFI_DEVICE_ERROR	The device reported an error while attempting to write data.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

12.11 Inline Cryptographic Interface Protocol

EFI_BLOCK_IO_CRYPTOPROTOCOL

Summary

The UEFI Inline Cryptographic Interface protocol provides services to abstract access to inline cryptographic capabilities.

The usage model of this protocol is similar to the one of the **EFI_STORAGE_SECURITY_COMMAND_PROTOCOL** where FDE (Full Disk Encryption) solutions leave ESP partition unprotected (unencrypted) allowing storage clients to continue using **EFI_BLOCK_IO_PROTOCOL** or **EFI_BLOCK_IO2_PROTOCOL** protocol interfaces to load OS boot components from ESP partition. For other partitions boot apps (including OS boot app) that are enlightened to take advantage of inline cryptographic capability will be empowered to use this new protocol.

GUID

```
#define EFI_BLOCK_IO_CRYPTO_PROTOCOL_GUID \
    {0xa00490ba,0x3f1a,0x4b4c,\
     {0xab,0x90,0x4f,0xa9,0x97,0x26,0xa1,0xe8}}
```

Protocol Interface Structure

```
typedef struct _EFI_BLOCK_IO_CRYPTO_PROTOCOL {
    EFI_BLOCK_IO_MEDIA *Media;
    EFI_BLOCK_IO_CRYPTO_RESET Reset;
    EFI_BLOCK_IO_CRYPTO_GET_CAPABILITIES GetCapabilities;
    EFI_BLOCK_IO_CRYPTO_SET_CONFIGURATION SetConfiguration;
    EFI_BLOCK_IO_CRYPTO_GET_CONFIGURATION GetConfiguration;
    EFI_BLOCK_IO_CRYPTO_READ_DEVICE_EXTENDED ReadExtended;
    EFI_BLOCK_IO_CRYPTO_WRITE_DEVICE_EXTENDED WriteExtended;
    EFI_BLOCK_IO_CRYPTO_FLUSH FlushBlocks;
} EFI_BLOCK_IO_CRYPTO_PROTOCOL;
```

Parameters

<i>Media</i>	A pointer to the EFI_BLOCK_IO_MEDIA data for this device. Type EFI_BLOCK_IO_MEDIA is defined in the EFI_BLOCK_IO_PROTOCOL section.
<i>Reset</i>	Reset the block device hardware.
<i>GetCapabilities</i>	Get the current capabilities of the ICI.
<i>SetConfiguration</i>	Set the configuration for the ICI instance.
<i>GetConfiguration</i>	Get the configuration for the ICI instance.
<i>ReadExtended</i>	Provide an extended version of the storage device read command.
<i>WriteExtended</i>	Provide an extended version of the storage device write command.
<i>FlushBlocks</i>	Flushes any cache blocks. This function is optional and only needs to be supported on block devices that cache writes.

Related Definitions

Some functions defined for this protocol require the caller to specify the device capabilities, keys and/or attributes of the keys to be used. These parameters must be consistent with the supported capabilities as reported by the device.

```
typedef struct {
    EFI_GUID Algorithm;
    UINT64 KeySize;
    UINT64 CryptoBlockSizeBitMask;
} EFI_BLOCK_IO_CRYPTO_CAPABILITY;
```

<i>Algorithm</i>	GUID of the algorithm.
<i>KeySize</i>	Specifies <i>KeySize</i> in bits used with this Algorithm.
<i>CryptoBlockSizeBitMask</i>	

Specifies bitmask of block sizes supported by this algorithm. Bit j being set means that 2^j bytes crypto block size is supported.

```
#define EFI_BLOCK_IO_CRYPTO_ALGO_GUID_AES_XTS \
    {0x2f87ba6a, \
     0x5c04, 0x4385, 0xa7, 0x80, 0xf3, 0xbf, 0x78, 0xa9, 0x7b, 0xec}
```

EFI_BLOCK_IO_CRYPTO_ALGO_GUID_AES_XTS GUID represents Inline Cryptographic Interface capability supporting AES XTS crypto algorithm as described in *IEEE Std 1619-2007: IEEE Standard for Cryptographic Protection of Data on Block-Oriented Storage Devices*.

```
typedef struct {
    EFI_BLOCK_IO_CRYPTO_IV_INPUT Header;
    UINT64 CryptoBlockNumber;
    UINT64 CryptoBlockSize;
} EFI_BLOCK_IO_CRYPTO_IV_INPUT_AES_XTS;
```

EFI_BLOCK_IO_CRYPTO_IV_INPUT_AES_XTS structure is used as `CryptoIvInput` parameter to the `ReadExtended` and `WriteExtended` methods for Inline Cryptographic Interface supporting and using AES XTS algorithm with IV input as defined for AES XTS algorithm. IO operation (read or write) range should consist of one or more blocks of *CryptoBlockSize* size.

CryptoBlockNumber is used as the AES XTS IV for the first crypto block and is incremented by one for each consecutive crypto block in the IO operation range.

```
#define
EFI_BLOCK_IO_CRYPTO_ALGO_GUID_AES_CBC_MICROSOFT_BITLOCKER \
    {0x689e4c62, \
     0x70bf, 0x4cf3, 0x88, 0xbb, 0x33, 0xb3, 0x18, 0x26, 0x86, 0x70}
```

EFI_BLOCK_IO_CRYPTO_ALGO_GUID_AES_CBC_MICROSOFT_BITLOCKER GUID represents Inline Cryptographic Interface capability supporting AES CBC crypto algorithm in the *non-diffuser* mode as described in following Microsoft white paper, section 4: See “Links to UEFI-Related Documents” (<http://uefi.org/uefi>) under the heading “Inline Cryptographic Interface--Bit Locker Cipher”. It is important to note that when excluding diffuser operations (A diffuser and B diffuser) described in the above document one should also exclude derivation of sector key and XOR-ing it with plaintext as that operation is part of the diffuser part of the algorithm and does not belong to the AES-CBC Microsoft BitLocker algorithm being referred to here.

```
typedef struct {
    EFI_BLOCK_IO_CRYPTO_IV_INPUT Header;
    UINT64 CryptoBlockByteOffset;
    UINT64 CryptoBlockSize;
} EFI_BLOCK_IO_CRYPTO_IV_INPUT_AES_CBC_MICROSOFT_BITLOCKER;
```

EFI_BLOCK_IO_CRYPTO_IV_INPUT_AES_CBC_MICROSOFT_BITLOCKER structure is used to pass as `CryptoIvInput` parameter to the `ReadExtended` and `WriteExtended` methods for Inline Cryptographic Interface supporting and using AES CBC algorithm with IV input as defined for Microsoft BitLocker Drive Encryption. IO operation (read or write) range should consist of one or more blocks of *CryptoBlockSize* size. *CryptoBlockByteOffset* is used as the AES CBC Microsoft BitLocker algorithm IV for the first crypto block and is incremented by *CryptoBlockSize* for each consecutive crypto block in the IO operation range.

```
typedef struct {
    UINT64      InputSize;
} EFI_BLOCK_IO_CRYPTO_IV_INPUT;
```

EFI_BLOCK_IO_CRYPTO_IV_INPUT structure is used as a common header in *CryptoIvInput* parameters passed to the ReadExtended and WriteExtended methods for Inline Cryptographic Interface. Its purpose is to pass size of the entire *CryptoIvInput* parameter memory buffer to the Inline Cryptographic Interface.

Further extensions of crypto algorithm support by Inline Cryptographic Interface should follow the same pattern established above for the AES XTS and AES CBC Microsoft BitLocker algorithms. In particular each added crypto algorithm should:

- Define its crypto algorithm GUID using following pattern:
#define EFI_BLOCK_IO_CRYPTO_ALGO_GUID_<algo-name> {<algo-guid>}
- Define its corresponding *CryptoIvInput* parameter structure and describe how it is populated for each IO operation (read / write):

```
typedef struct {
    EFI_BLOCK_IO_CRYPTO_IV_INPUT      Header;
    <TBD>                               <TBD>;
} EFI_BLOCK_IO_CRYPTO_IV_INPUT_<algo-name>;
```

```
#define EFI_BLOCK_IO_CRYPTO_INDEX_ANY 0xFFFFFFFFFFFFFFFF
typedef struct {
    BOOLEAN      Supported;
    UINT64      KeyCount;
    UINT64      CapabilityCount;
    EFI_BLOCK_IO_CRYPTO_CAPABILITY Capabilities[1];
} EFI_BLOCK_IO_CRYPTO_CAPABILITIES;
```

<i>Supported</i>	Is inline cryptographic capability supported on this device.
<i>KeyCount</i>	Maximum number of keys that can be configured at the same time.
<i>CapabilityCount</i>	Number of supported capabilities.
<i>Capabilities</i>	Array of supported capabilities.

```
typedef struct {
    UINT64      Index;
    EFI_GUID      KeyOwnerGuid;
    EFI_BLOCK_IO_CRYPTO_CAPABILITY Capability;
    VOID      *CryptoKey;
} EFI_BLOCK_IO_CRYPTO_CONFIGURATION_TABLE_ENTRY;
```

<i>Index</i>	Configuration table index. A special Index EFI_BLOCK_IO_CRYPTO_INDEX_ANY can be used to set any available entry in the configuration table.
<i>KeyOwnerGuid</i>	Identifies the owner of the configuration table entry. Entry can also be used with the Nil value to clear key from the configuration table index.
<i>Capability</i>	A supported capability to be used. The <i>CryptoBlockSizeBitMask</i> field of the structure should have only one bit set from the supported mask.
<i>CryptoKey</i>	Pointer to the key. The size of the key is defined by the <i>KeySize</i> field of the capability specified by the Capability parameter.

```
typedef struct {
    UINT64 Index;
    EFI_GUID KeyOwnerGuid;
    EFI_BLOCK_IO_CRYPTO_CAPABILITY Capability;
} EFI_BLOCK_IO_CRYPTO_RESPONSE_CONFIGURATION_ENTRY;
```

<i>Index</i>	Configuration table index.
<i>KeyOwnerGuid</i>	Identifies the current owner of the entry.
<i>Capability</i>	The capability to be used. The <i>CryptoBlockSizeBitMask</i> field of the structure has only one bit set from the supported mask.

Description

The **EFI_BLOCK_IO_CRYPTO_PROTOCOL** defines a UEFI protocol that can be used by UEFI drivers and applications to perform block encryption on a storage device, such as UFS.

The **EFI_BLOCK_IO_CRYPTO_PROTOCOL** instance will be on the same handle as the device path of the inline encryption device.

While this protocol is intended to abstract the encryption process for block device access, the protocol user does not have to be aware of the specific underlying encryption hardware.

EFI_BLOCK_IO_CRYPTO_PROTOCOL.Reset()

Summary

Resets the block device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_RESET) (
    IN EFI_BLOCK_IO_CRYPTO_PROTOCOL *This,
    IN BOOLEAN                      ExtendedVerification
);
```

Parameters

This Pointer to the **EFI_BLOCK_IO_CRYPTO_PROTOCOL** instance.

ExtendedVerification Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The **Reset ()** function resets the block device hardware.

As part of the initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the *ExtendedVerification* flag is TRUE the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The block device was reset.
EFI_DEVICE_ERROR	The block device is not functioning correctly and could not be reset.
EFI_INVALID_PARAMETER	<i>This</i> is NULL.

EFI_BLOCK_IO_CRYPTO_PROTOCOL.GetCapabilities()

Summary

Get the capabilities of the underlying inline cryptographic interface.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_GET_CAPABILITIES) (
    IN EFI_BLOCK_IO_CRYPTO_PROTOCOL          *This,
    OUT EFI_BLOCK_IO_CRYPTO_CAPABILITIES    *Capabilities
);
```

Parameters

This Pointer to the **EFI_BLOCK_IO_CRYPTO_PROTOCOL** instance.

Capabilities Pointer to the **EFI_BLOCK_IO_CRYPTO_CAPABILITIES** structure.

Description

The **GetCapabilities()** function determines whether pre-OS controllable inline crypto is supported by the system for the current disk and, if so, returns the capabilities of the crypto engine.

The caller is responsible for providing the Capabilities structure with a sufficient number of entries. If the structure is too small, the **EFI_BUFFER_TOO_SMALL** error code is returned and the CapabilityCount field contains the number of entries needed to contain the capabilities.

Status Codes Returned

EFI_SUCCESS	The ICI is ready for use.
EFI_BUFFER_TOO_SMALL	The Capabilities structure was too small. The number of entries needed is returned in the CapabilityCount field of the structure.
EFI_NO_RESPONSE	No response was received from the ICI
EFI_DEVICE_ERROR	An error occurred when attempting to access the ICI
EFI_INVALID_PARAMETER	<i>This</i> is NULL .
EFI_INVALID_PARAMETER	Capabilities is NULL

EFI_BLOCK_IO_CRYPTO_PROTOCOL.SetConfiguration()

Summary

Set the configuration of the underlying inline cryptographic interface.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_SET_CONFIGURATION) (
    IN EFI_BLOCK_IO_CRYPTO_PROTOCOL          *This,
    IN UINT64                                ConfigurationCount,
    IN EFI_BLOCK_IO_CRYPTO_CONFIGURATION_TABLE_ENTRY
    *ConfigurationTable,
    OUT EFI_BLOCK_IO_CRYPTO_RESPONSE_CONFIGURATION_ENTRY
    *ResultingTable OPTIONAL
);
```

Parameters

<i>This</i>	Pointer to the EFI_BLOCK_IO_CRYPTO_PROTOCOL instance.
<i>ConfigurationCount</i>	Number of entries being configured with this call.
<i>ConfigurationTable</i>	Pointer to a table used to populate the configuration table.
<i>ResultingTable</i>	Optional pointer to a table that receives the newly configured entries.

Description

The **SetConfiguration()** function allows the user to set the current configuration of the inline cryptographic interface and should be called before attempting any crypto operations.

This configures the configuration table entries with algorithms, key sizes and keys. Each configured entry can later be referred to by index at the time of storage transaction.

The configuration table index will refer to the combination of KeyOwnerGuid, Algorithm, and CryptoKey.

KeyOwnerGuid identifies the component taking ownership of the entry. It helps components to identify their own entries, cooperate with other owner components, and avoid conflicts. This Guid identifier is there to help coordination between cooperating components and not a security or synchronization feature. The Nil GUID can be used by a component to release use of entry owned. It is also used to identify potentially available entries (see GetConfiguration).

CryptoKey specifies algorithm-specific key material to use within parameters of selected crypto capability.

This function is called infrequently – typically once, on device start, before IO starts. It can be called at later times in cases the number of keys used on the drive is higher than what can be configured at a time or a new key has to be added.

Components setting or changing an entry or entries for a given index or indices must ensure that IO referencing affected indices is temporarily blocked (run-down) at the time of change.

Indices parameters in each parameter table entry allow to set only a portion of the available table entries in the crypto module anywhere from single entry to entire table supported.

If corresponding table entry or entries being set are already in use by another owner the call should be failed and none of the entries should be modified. The interface implementation must enforce atomicity of this operation (should either succeed fully or fail completely without modifying state). Note that components using GetConfiguration command to discover available entries should be prepared that by the time of calling SetConfiguration the previously available entry may have become occupied. Such components should be prepared to re-try the sequence of operations. Alternatively **EFI_BLOCK_IO_CRYPTO_INDEX_ANY** can be used to have the implementation discover and allocate available, if any, indices atomically.

An optional ResultingTable pointer can be provided by the caller to receive the newly configured entries. The array provided by the caller must have at least ConfigurationCount of entries.

Status Codes Returned

EFI_SUCCESS	The ICI is ready for use.
EFI_NO_RESPONSE	No response was received from the ICI
EFI_DEVICE_ERROR	An error occurred when attempting to access the ICI
EFI_INVALID_PARAMETER	<i>This is NULL.</i>
EFI_INVALID_PARAMETER	<i>ConfigurationTable is NULL</i>
EFI_INVALID_PARAMETER	<i>ConfigurationCount is 0</i>
EFI_OUT_OF_RESOURCES	Could not find the requested number of available entries in the configuration table.

EFI_BLOCK_IO_CRYPTO_PROTOCOL.GetConfiguration()

Summary

Get the configuration of the underlying inline cryptographic interface.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_GET_CONFIGURATION) (
    IN EFI_BLOCK_IO_CRYPTO_PROTOCOL    *This,
    IN UINT64                          StartIndex,
    IN UINT64                          ConfigurationCount,
    IN EFI_GUID                        *KeyOwnerGuid OPTIONAL,
    OUT EFI_BLOCK_IO_CRYPTO_RESPONSE_CONFIGURATION_ENTRY
    *ConfigurationTable
);
```

Parameters

<i>This</i>	Pointer to the EFI_BLOCK_IO_CRYPTO_PROTOCOL instance.
<i>StartIndex</i>	Configuration table index at which to start the configuration query.
<i>ConfigurationCount</i>	Number of entries to return in the response table.
<i>KeyOwnerGuid</i>	Optional parameter to filter response down to entries with a given owner. A pointer to the Nil value can be used to return available entries. Set to NULL when no owner filtering is required.
<i>ConfigurationTable</i>	Table of configured configuration table entries (with no CryptoKey returned): configuration table index, <i>KeyOwnerGuid</i> , Capability. Should have sufficient space to store up to <i>ConfigurationCount</i> entries.

Description

The **GetConfiguration()** function allows the user to get the configuration of the inline cryptographic interface.

Retrieves, entirely or partially, the currently configured key table. Note that the keys themselves are not retrieved, but rather just indices, owner GUIDs and capabilities.

If fewer entries than specified by *ConfigurationCount* are returned, the Index field of the unused entries is set to **EFI_BLOCK_IO_CRYPTO_INDEX_ANY**.

Status Codes Returned

EFI_SUCCESS	The ICI is ready for use.
EFI_NO_RESPONSE	No response was received from the ICI
EFI_DEVICE_ERROR	An error occurred when attempting to access the ICI
EFI_INVALID_PARAMETER	<i>This</i> is NULL .

Unified Extensible Firmware Interface Specification

EFI_INVALID_PARAMETER	Configuration table is NULL
EFI_INVALID_PARAMETER	<i>StartIndex</i> is out of bounds

EFI_BLOCK_IO_CRYPTO_PROTOCOL.ReadExtended()

Summary

Reads the requested number of blocks from the device and optionally decrypts them inline.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_READ_EXTENDED) (
    IN EFI_BLOCK_IO_CRYPTO_PROTOCOL      *This,
    IN UINT32                             MediaId,
    IN EFI_LBA                             LBA,
    IN OUT EFI_BLOCK_IO_CRYPTO_TOKEN     *Token,
    IN UINT64                             BufferSize,
    OUT VOID                              *Buffer,
    IN UINT64                             *Index OPTIONAL,
    IN VOID                              *CryptoIvInput OPTIONAL
);
```

Parameters

<i>This</i>	Pointer to the EFI_BLOCK_IO_CRYPTO_PROTOCOL instance.
<i>MediaId</i>	The media ID that the read request is for.
<i>LBA</i>	The starting logical block address to read from on the device. Type EFI_LBA is defined in the EFI_BLOCK_IO_PROTOCOL description.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_BLOCK_IO_CRYPTO_TOKEN is defined in “Related Definitions” below.
<i>BufferSize</i>	The size of the <i>Buffer</i> in bytes. This must be a multiple of the intrinsic block size of the device.
<i>Buffer</i>	A pointer to the destination buffer for the data. The caller is responsible for either having implicit or explicit ownership of the buffer.
<i>Index</i>	A pointer to the configuration table index. This is optional.
<i>CryptoIvInput</i>	A pointer to a buffer that contains additional cryptographic parameters as required by the capability referenced by the configuration table index, such as cryptographic initialization vector.

Description

The **ReadExtended()** function allows the caller to perform a storage device read operation. The function reads the requested number of blocks from the device and then if *Index* is specified decrypts them inline. All the blocks are read and decrypted (if decryption requested), or an error is returned.

If there is no media in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID for the current media in the device, the function returns **EFI_MEDIA_CHANGED**.

If **EFI_DEVICE_ERROR**, **EFI_NO_MEDIA**, or **EFI_MEDIA_CHANGED** is returned and non-blocking I/O is being used, the *Event* associated with this request will not be signaled.

In addition to standard storage transaction parameters (LBA, IO size, and buffer), this command will also specify a configuration table *Index* and *CryptoIvInput* when data has to be decrypted inline by the controller after being read from the storage device. If an *Index* parameter is not specified, no decryption is performed.

Related Definitions

```
typedef struct {
    EFI_EVENT          Event;
    EFI_STATUS        TransactionStatus;
} EFI_BLOCK_IO_CRYPTO_TOKEN;
```

Event If *Event* is NULL, then blocking I/O is performed. If *Event* is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the read request is completed and data was decrypted (when *Index* was specified).

TransactionStatus Defines whether or not the signaled event encountered an error.

Status Codes Returned

EFI_SUCCESS	The read request was queued if Token-> Event is not NULL. The data was read correctly from the device if the Token-> Event is NULL.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the read operation and/or decryption operation.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.
EFI_BAD_BUFFER_SIZE	The <i>BufferSize</i> parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	<i>This</i> is NULL, or the read request contains LBAs that are not valid, or the buffer is not on proper alignment
EFI_INVALID_PARAMETER	<i>CryptoIvInput</i> is incorrect.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_BLOCK_IO_CRYPTO_PROTOCOL.WriteExtended()

Summary

Optionally encrypts a specified number of blocks inline and then writes to the device.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_WRITE_EXTENDED) (
    IN EFI_BLOCK_IO_CRYPTO_PROTOCOL      *This,
    IN UINT32                             MediaId,
    IN EFI_LBA                             LBA,
    IN OUT EFI_BLOCK_IO_CRYPTO_TOKEN      *Token,
    IN UINT64                             BufferSize,
    IN VOID                               *Buffer,
    IN UINT64                             *Index, OPTIONAL
    IN VOID                               *CryptoIvInput OPTIONAL
);
```

Parameters

<i>This</i>	Pointer to the EFI_BLOCK_IO_CRYPTO_PROTOCOL instance.
<i>MediaId</i>	The media ID that the read request is for.
<i>LBA</i>	The starting logical block address to read from on the device. Type EFI_LBA is defined in the EFI_BLOCK_IO_PROTOCOL description.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_BLOCK_IO_CRYPTO_TOKEN is defined in “Related Definitions” section for ReadExtended() function above.
<i>BufferSize</i>	The size of the <i>Buffer</i> in bytes. This must be a multiple of the intrinsic block size of the device.
<i>Buffer</i>	A pointer to the source buffer for the data.
<i>Index</i>	A pointer to the configuration table index. This is optional.
<i>CryptoIvInput</i>	A pointer to a buffer that contains additional cryptographic parameters as required by the capability referenced by the configuration table index, such as cryptographic initialization vector.

Description

The **WriteExtended()** function allows the caller to perform a storage device write operation. The function encrypts the requested number of blocks inline if *Index* is specified and then writes them to the device. All the blocks are encrypted (if encryption requested) and written, or an error is returned.

If there is no media in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID for the current media in the device, the function returns **EFI_MEDIA_CHANGED**.

If **EFI_DEVICE_ERROR**, **EFI_NO_MEDIA**, **EFI_WRITE_PROTECTED** or **EFI_MEDIA_CHANGED** is returned and non-blocking I/O is being used, the *Event* associated with this request will not be signaled.

In addition to standard storage transaction parameters (LBA, IO size, and buffer), this command will also specify a configuration table *Index* and a *CryptoIvInput* when data has to be encrypted inline by the controller before being written to the storage device. If no *Index* parameter is specified, no encryption is performed.

Status Codes Returned

EFI_SUCCESS	The request to encrypt (optionally) and write was queued if Event is not NULL. The data was encrypted (optionally) and written correctly to the device if the Event is NULL.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.
EFI_DEVICE_ERROR	The device reported an error while attempting to encrypt blocks or to perform the write operation.
EFI_BAD_BUFFER_SIZE	The <i>BufferSize</i> parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	<i>This is NULL</i> , or the write request contains LBAs that are not valid, or the buffer is not on proper alignment.
EFI_INVALID_PARAMETER	<i>CryptoIvInput</i> is incorrect.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_BLOCK_IO_CRYPTO_PROTOCOL.FlushBlocks()

Summary

Flushes all modified data to a physical block device.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_FLUSH) (
    IN EFI_BLOCK_IO_CRYPTO_PROTOCOL    *This,
    IN OUT EFI_BLOCK_IO_CRYPTO_TOKEN  *Token
);
```

Parameters

<i>This</i>	Pointer to the EFI_BLOCK_IO_CRYPTO_PROTOCOL instance.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_BLOCK_IO_CRYPTO_TOKEN is defined in “Related Definitions” section for ReadExtended() function above.

Description

The **FlushBlocks()** function flushes all modified data to the physical block device. Any modified data that has to be encrypted must have been already encrypted as a part of **WriteExtended()** operation – inline crypto operation cannot be a part of flush operation.

All data written to the device prior to the flush must be physically written before returning **EFI_SUCCESS** from this function. This would include any cached data the driver may have cached, and cached data the device may have cached. A flush may cause a read request following the flush to force a device access.

If **EFI_DEVICE_ERROR**, **EFI_NO_MEDIA**, **EFI_WRITE_PROTECTED** or **EFI_MEDIA_CHANGED** is returned and non-blocking I/O is being used, the *Event* associated with this request will not be signaled.

Status Codes Returned

EFI_SUCCESS	The flush request was queued if <i>Event</i> is not NULL. All outstanding data was written correctly to the device if the <i>Event</i> is NULL.
EFI_DEVICE_ERROR	The device reported an error while attempting to write data.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.
EFI_INVALID_PARAMETER	<i>This is NULL.</i>
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

12.12 Erase Block Protocol

EFI_ERASE_BLOCK_PROTOCOL

Summary

This protocol provides the ability for a device to expose erase functionality. This optional protocol is installed on the same handle as the **EFI_BLOCK_IO_PROTOCOL** or **EFI_BLOCK_IO2_PROTOCOL**.

GUID

```
#define EFI_ERASE_BLOCK_PROTOCOL_GUID \
{0x95A9A93E, 0x A86E, 0x4926, \
{0xaa, 0xef, 0x99, 0x18, 0xe7, 0x72, 0xd9, 0x87}}
```

Revision Number

```
#define EFI_ERASE_BLOCK_PROTOCOL_REVISION ((2<<16) | (60))
```

Protocol Interface Structure

```
typedef struct _EFI_ERASE_BLOCK_PROTOCOL {
    UINT64                Revision;
    UINT32                EraseLengthGranularity;
    EFI_BLOCK_ERASE      EraseBlocks;
} EFI_ERASE_BLOCK_PROTOCOL;
```

Parameters

Revision The revision to which the **EFI_ERASE_BLOCK_PROTOCOL** adheres. All future revisions must be backwards compatible. If a future version is not backwards compatible, it is not the same GUID.

EraseLengthGranularity

Returns the erase length granularity as a number of logical blocks. A value of 1 means the erase granularity is one logical block.

EraseBlocks

Erase the requested number of blocks from the device. See the **EraseBlocks ()** function description.

EFI_ERASE_BLOCK_PROTOCOL.EraseBlocks()

Summary

Erase a specified number of device blocks.

Prototype

```

Typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_ERASE)
IN EFI_BLOCK_IO_PROTOCOL      *This,
IN UINT32                    MediaId,
IN EFI_LBA                  LBA,
IN OUT EFI_ERASE_BLOCK_TOKEN *Token,
IN UINTN                    Size
);

```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type is defined in the EFI_ERASE_BLOCK_PROTOCOL description.
<i>MediaId</i>	The media ID that the erase request is for.
<i>LBA</i>	The starting logical block address to be erased. The caller is responsible for erasing only legitimate locations. Type EFI_LBA is defined in the EFI_BLOCK_IO_PROTOCOL description.
<i>Token</i>	A pointer to the token associated with the transaction. Type EFI_ERASE_BLOCK_TOKEN is defined in "Related Definitions" below.
<i>Size</i>	The size in bytes to be erased. This must be a multiple of the physical block size of the device.

Description

The **EraseBlocks()** function erases the requested number of device blocks. Upon the successful execution of **EraseBlocks()** with an **EFI_SUCCESS** return code, any subsequent reads of the same LBA range would return an initialized/formatted value.

If there is no media in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID for the current media in the device, the function returns **EFI_MEDIA_CHANGED**. The function must return **EFI_NO_MEDIA** or **EFI_MEDIA_CHANGED** even if *LBA* or *Size* are invalid so the caller can probe for changes in media state.

It is the intention of the **EraseBlocks()** operation to be at least as performant as writing zeroes to each of the specified LBA locations while ensuring the equivalent security.

On some devices, the granularity of the erasable units is defined by *EraseLengthGranularity* which is the smallest number of consecutive blocks which can be addressed for erase. The size of the *EraseLengthGranularity* is device specific and can be obtained from **EFI_ERASE_BLOCK_MEDIA** structure. The fields of **EFI_ERASE_BLOCK_MEDIA** are not the same as

EFI_BLOCK_IO_MEDIA, so look at the **EFI_BLOCK_IO_PROTOCOL** and/or **EFI_BLOCK_IO2_PROTOCOL** on the handle for the complete list of fields, if needed. For optimal performance, the starting **LBA** to be erased shall be *EraseLengthGranularity* aligned and the Size shall be an integer multiple of an *EraseLengthGranularity*.

Related Definitions

```
typedef struct {
    EFI_EVENT      Event;
    EFI_STATUS     TransactionStatus;
} EFI_ERASE_BLOCK_TOKEN;
```

Event If *Event* is **NULL**, then blocking I/O is performed. If *Event* is not **NULL** and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the erase request is completed.

TransactionStatus Defines whether the signaled event encountered an error.

Status Codes Returned

EFI_SUCCESS	The erase request was queued if <i>Event</i> is not NULL . The data was erased correctly to the device if the <i>Event</i> is NULL .to the device.
EFI_WRITE_PROTECTED	The device cannot be erased due to write protection.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the erase operation.
EFI_INVALID_PARAMETER	The erase request contains LBAs that are not valid.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.

12.13 ATA Pass Thru Protocol

EFI_ATA_PASS_THRU_PROTOCOL

This section provides a detailed description of the **EFI_ATA_PASS_THRU_PROTOCOL**.

Summary

Provides services that allow ATA commands to be sent to ATA Devices attached to an ATA controller. Packet-based commands would be sent to ATAPI devices only through the Extended SCSI Pass Thru Protocol. While the **ATA_PASS_THRU** interface would expose an interface to the underlying ATA devices on an ATA controller, **EXT_SCSI_PASS_THRU** is responsible for exposing a packet-based command interface for the ATAPI devices on the same ATA controller.

GUID

```
#define EFI_ATA_PASS_THRU_PROTOCOL_GUID \
  {0x1d3de7f0,0x807,0x424f,\
   {0xaa,0x69,0x11,0xa5,0x4e,0x19,0xa4,0x6f}}
```

Protocol Interface Structure

```
typedef struct _EFI_ATA_PASS_THRU_PROTOCOL {
  EFI_ATA_PASS_THRU_MODE           *Mode;
  EFI_ATA_PASS_THRU_PASSTHRU       PassThru;
  EFI_ATA_PASS_THRU_GET_NEXT_PORT   GetNextPort;
  EFI_ATA_PASS_THRU_GET_NEXT_DEVICE GetNextDevice;
  EFI_ATA_PASS_THRU_BUILD_DEVICE_PATH BuildDevicePath;
  EFI_ATA_PASS_THRU_GET_DEVICE      GetDevice;
  EFI_ATA_PASS_THRU_RESET_PORT      ResetPort;
  EFI_ATA_PASS_THRU_RESET_DEVICE    ResetDevice;
} EFI_ATA_PASS_THRU_PROTOCOL;
```

Parameters

Mode

A pointer to the **EFI_ATA_PASS_THRU_MODE** data for this ATA controller. **EFI_ATA_PASS_THRU_MODE** is defined in “Related Definitions” below.

PassThru

Sends an ATA command to an ATA device that is connected to the ATA controller. See the **PassThru()** function description.

GetNextPort

Retrieves the list of legal ports for ATA devices on an ATA controller. See the **GetNextPort()** function description.

GetNextDevice

Retrieves the list of legal ATA devices on a specific port of an ATA controller. See the **GetNextDevice()** function description.

BuildDevicePath

Allocates and builds a device path node for an ATA Device on an ATA controller. See the **BuildDevicePath()** function description.

GetDevice

Translates a device path node to a port and port multiplier port. See the **GetDevice()** function description.

ResetPort

Resets an ATA port or channel (PATA). This operation resets all the ATA devices connected to the ATA port or channel. See the **ResetPort()** function description.

ResetDevice

Resets an ATA device that is connected to the ATA controller. See the **ResetDevice()** function description.

Note: The following data values in the **EFI_ATA_PASS_THRU_MODE** interface are read-only.

Attributes

Additional information on the attributes of the ATA controller. See “Related Definitions” below for the list of possible attributes.

IoAlign

Supplies the alignment requirement for any buffer used in a data transfer. *IoAlign* values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, *IoAlign* must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by *IoAlign* with no remainder.

Related Definitions

```
typedef struct {
    UINT32 Attributes;
    UINT32 IoAlign;
} EFI_ATA_PASS_THRU_MODE;
```

```
#define EFI_ATA_PASS_THRU_ATTRIBUTES_PHYSICAL    0x0001
```

```
#define EFI_ATA_PASS_THRU_ATTRIBUTES_LOGICAL     0x0002
```

```
#define EFI_ATA_PASS_THRU_ATTRIBUTES_NONBLOCKIO 0x0004
```

EFI_ATA_PASS_THRU_ATTRIBUTES_PHYSICAL

If this bit is set, then the **EFI_ATA_PASS_THRU_PROTOCOL** interface is for physical devices on the ATA controller.

EFI_ATA_PASS_THRU_ATTRIBUTES_LOGICAL

If this bit is set, then the **EFI_ATA_PASS_THRU_PROTOCOL** interface is for logical devices on the ATA controller.

EFI_ATA_PASS_THRU_ATTRIBUTES_NONBLOCKIO

If this bit is set, then the **EFI_ATA_PASS_THRU_PROTOCOL** interface supports non blocking I/O. Every **EFI_ATA_PASS_THRU_PROTOCOL** must support blocking I/O. The support of non-blocking I/O is optional.

Description

The **EFI_ATA_PASS_THRU_PROTOCOL** provides information about an ATA controller and the ability to send ATA Command Blocks to any ATA device attached to that ATA controller. To send ATAPI command blocks to ATAPI device attached to that ATA controller, use the **EXT_SCSI_PASS_THRU_PROTOCOL** interface.

The ATAPI devices support a small set of the non-packet-based ATA commands. The **EFI_ATA_PASS_THRU_PROTOCOL** may be used to send such ATA commands to ATAPI devices.

The printable name for the controller can be provided through the **EFI_COMPONENT_NAME2_PROTOCOL** for multiple languages.

The *Attributes* field of the Mode member of the **EFI_ATA_PASS_THRU_PROTOCOL** interface tells if the interface is for physical ATA devices or logical ATA devices. Drivers for non-RAID ATA controllers will set both the **EFI_ATA_PASS_THRU_ATTRIBUTES_PHYSICAL**, and the **EFI_ATA_PASS_THRU_ATTRIBUTES_LOGICAL** bits.

Drivers for RAID controllers that allow access to the physical devices and logical devices will produce two **EFI_ATA_PASS_THRU_PROTOCOL** interfaces: one with the just the **EFI_ATA_PASS_THRU_ATTRIBUTES_PHYSICAL** bit set and another with just the **EFI_ATA_PASS_THRU_ATTRIBUTES_LOGICAL** bit set. One interface can be used to access the physical devices attached to the RAID controller, and the other can be used to access the logical devices attached to the RAID controller for its current configuration.

Drivers for RAID controllers that do not allow access to the physical devices will produce one **EFI_ATA_PASS_THROUGH_PROTOCOL** interface with just the **EFI_ATA_PASS_THRU_LOGICAL** bit set. The interface for logical devices can also be used by a file system driver to mount the RAID volumes. An **EFI_ATA_PASS_THRU_PROTOCOL** with neither **EFI_ATA_PASS_THRU_ATTRIBUTES_LOGICAL** nor **EFI_ATA_PASS_THRU_ATTRIBUTES_PHYSICAL** set is an illegal configuration.

The Attributes field also contains the **EFI_ATA_PASS_THRU_ATTRIBUTES_NONBLOCKIO** bit. All **EFI_ATA_PASS_THRU_PROTOCOL** interfaces must support blocking I/O. If this bit is set, then the interface supports both blocking I/O and non-blocking I/O.

Each **EFI_ATA_PASS_THRU_PROTOCOL** instance must have an associated device path. Typically this will have an ACPI device path node and a PCI device path node, although variation will exist.

Additional information about the ATA controller can be obtained from protocols attached to the same handle as the **EFI_ATA_PASS_THRU_PROTOCOL**, or one of its parent handles. This would include the device I/O abstraction used to access the internal registers and functions of the ATA controller.

This protocol may also be used for PATA devices (or devices in a PATA-compatible mode). PATA devices are mapped to ports and port multiplier ports using the following table:

Table 109. PATA device mapping to ports and port multiplier ports

PATA Device Connection	Emulated Port Number	Emulated Port Multiplier Port Number
Primary Master	0	0
Primary Slave	0	1
Secondary Master	1	0
Secondary Slave	1	1

EFI_ATA_PASS_THRU_PROTOCOL.PassThru()

Summary

Sends an ATA command to an ATA device that is attached to the ATA controller. This function supports both blocking I/O and non-blocking I/O. The blocking I/O functionality is required, and the non-blocking I/O functionality is optional.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_PASSTHRU) (
    IN      EFI_ATA_PASS_THRU_PROTOCOL      *This,
    IN      UINT16                          Port,
    IN      UINT16                          PortMultiplierPort,
    IN OUT  EFI_ATA_PASS_THRU_COMMAND_PACKET *Packet,
    IN      EFI_EVENT                        Event OPTIONAL
);
```

Parameters

This

A pointer to the **EFI_ATA_PASS_THRU_PROTOCOL** instance.

Port

The port number of the ATA device to send the command.

PortMultiplierPort

The port multiplier port number of the ATA device to send the command. If there is no port multiplier, then specify 0xFFFF.

Packet

A pointer to the ATA command to send to the ATA device specified by *Port* and *PortMultiplierPort*. See “Related Definitions” below for a description of **EFI_ATA_PASS_THRU_COMMAND_PACKET**.

Event

If non-blocking I/O is not supported then *Event* is ignored, and blocking I/O is performed. If *Event* is **NULL**, then blocking I/O is performed. If *Event* is not **NULL** and non blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the ATA command completes.

Related Definitions

```
typedef struct {
    EFI_ATA_STATUS_BLOCK      *Asb;
    EFI_ATA_COMMAND_BLOCK    *Acb;
    UINT64                    Timeout;
    VOID                      *InDataBuffer;
    VOID                      *OutDataBuffer;
    UINT32                    InTransferLength;
    UINT32                    OutTransferLength;
    EFI_ATA_PASS_THRU_CMD_PROTOCOL Protocol;
    EFI_ATA_PASS_THRU_LENGTH Length;
} EFI_ATA_PASS_THRU_COMMAND_PACKET;
```

Timeout

The timeout, in 100 ns units, to use for the execution of this ATA command. A *Timeout* value of 0 means that this function will wait indefinitely for the ATA command to execute. If *Timeout* is greater than zero, then this function will return **EFI_TIMEOUT** if the time required to execute the ATA command is greater than *Timeout*.

InDataBuffer

A pointer to the data buffer to transfer between the ATA controller and the ATA device for read and bidirectional commands. For all write and non data commands where *InTransferLength* is 0 this field is optional and may be **NULL**. If this field is not **NULL**, then it must be aligned on the boundary specified by the *IoAlign* field in the **EFI_ATA_PASS_THRU_MODE** structure.

OutDataBuffer

A pointer to the data buffer to transfer between the ATA controller and the ATA device for write or bidirectional commands. For all read and non data commands where *OutTransferLength* is 0 this field is optional and may be **NULL**. If this field is not **NULL**, then it must be aligned on the boundary specified by the *IoAlign* field in the **EFI_ATA_PASS_THRU_MODE** structure.

InTransferLength

On input, the size, in bytes, of *InDataBuffer*. On output, the number of bytes transferred between the ATA controller and the ATA device. If *InTransferLength* is larger than the ATA controller can handle, no data will be transferred, *InTransferLength* will be updated to contain the number of bytes that the ATA controller is able to transfer, and **EFI_BAD_BUFFER_SIZE** will be returned.

OutTransferLength

On Input, the size, in bytes of *OutDataBuffer*. On Output, the Number of bytes transferred between ATA Controller and the ATA device. If *OutTransferLength* is larger than the ATA controller can handle, no data will be transferred,

OutTransferLength will be updated to contain the number of bytes that the ATA controller is able to transfer, and **EFI_BAD_BUFFER_SIZE** will be returned.

Asb

A pointer to the sense data that was generated by the execution of the ATA command. It must be aligned to the boundary specified in the *IoAlign* field in the **EFI_ATA_PASS_THRU_MODE** structure.

Acb

A pointer to buffer that contains the Command Data Block to send to the ATA device specified by *Port* and *PortMultiplierPort*.

Protocol

Specifies the protocol used when the ATA device executes the command. Type **EFI_ATA_PASS_THRU_CMD_PROTOCOL** is defined below.

Length

Specifies the way in which the ATA command length is encoded. Type **EFI_ATA_PASS_THRU_LENGTH** is defined below.

```
typedef struct _EFI_ATA_COMMAND_BLOCK {
    UINT8 Reserved1[2];
    UINT8 AtaCommand;

#define EFI_ATA_PASS_THRU_LENGTH_COUNT             0x0F

```

Description

The `PassThru()` function sends the ATA command specified by `Packet` to the ATA device specified by `Port` and `PortMultiplierPort`. If the driver supports non-blocking I/O and `Event` is not `NULL`, then the driver will return immediately after the command is sent to the selected device, and will later signal `Event` when the command has completed.

If the driver supports non-blocking I/O and `Event` is `NULL`, then the driver will send the command to the selected device and block until it is complete. If the driver does not support non-blocking I/O, then the `Event` parameter is ignored, and the driver will send the command to the selected device and block until it is complete.

If `Packet` is successfully sent to the ATA device, then `EFI_SUCCESS` is returned. If `Packet` cannot be sent because there are too many packets already queued up, then `EFI_NOT_READY` is returned. The caller may retry `Packet` at a later time. If a device error occurs while sending the `Packet`, then `EFI_DEVICE_ERROR` is returned. If a timeout occurs during the execution of `Packet`, then `EFI_TIMEOUT` is returned.

If `Port` or `PortMultiplierPort` are not in a valid range for the ATA controller, then `EFI_INVALID_PARAMETER` is returned. If `InDataBuffer`, `OutDataBuffer` or `Asb` do not meet the alignment requirement specified by the `IoAlign` field of the `EFI_ATA_PASS_THRU_MODE` structure, then `EFI_INVALID_PARAMETER` is returned. If any of the other fields of `Packet` are invalid, then `EFI_INVALID_PARAMETER` is returned.

If the data buffer described by `InDataBuffer` and `InTransferLength` is too big to be transferred in a single command, then no data is transferred and `EFI_BAD_BUFFER_SIZE` is returned. The number of bytes that can be transferred in a single command are returned in `InTransferLength`. If the data buffer described by `OutDataBuffer` and `OutTransferLength` is too big to be transferred in a single command, then no data is transferred and `EFI_BAD_BUFFER_SIZE` is returned. The number of bytes that can be transferred in a single command are returned in `OutTransferLength`.

If the command described in *Packet* is not supported by the host adapter, then **EFI_UNSUPPORTED** is returned.

If **EFI_SUCCESS**, **EFI_BAD_BUFFER_SIZE**, **EFI_DEVICE_ERROR**, or **EFI_TIMEOUT** is returned, then the caller must examine *Asb*.

If non-blocking I/O is being used, then the status fields in *Packet* will not be valid until the *Event* associated with *Packet* is signaled.

If **EFI_NOT_READY**, **EFI_INVALID_PARAMETER** or **EFI_UNSUPPORTED** is returned, then *Packet* was never sent, so the status fields in *Packet* are not valid. If non-blocking I/O is being used, the *Event* associated with *Packet* will not be signaled.

This function will determine if data transfer is necessary based on the *Acb->Protocol* and *Acb->Length* fields. The *Acb->AtaCommand* field is ignored except to copy it into the ATA Command register. The following table describes special programming considerations based on the protocol specified by *Acb->Protocol*.

Table 110. Special programming considerations

Protocol Value	Description
EFI_ATA_PASS_THRU_PROTOCOL_ATA_HARDWARE_RESET	For PATA devices, then RST- is asserted. For SATA devices, then COMRESET will be issued.
EFI_ATA_PASS_THRU_PROTOCOL_ATA_SOFTWARE_RESET	A software reset will be issued to the ATA device.
EFI_ATA_PASS_THRU_PROTOCOL_PIO_DATA_IN - EFI_ATA_PASS_THRU_PROTOCOL_FPDMA	The command is sent to the ATA device. If the value is inappropriate for the command specified by <i>Acb->AtaCommand</i> , the results are undefined.
EFI_ATA_PASS_THRU_RETURN_RESPONSE	This command will only return the contents of the ATA status block.

The ATA host and the ATA device should already be configured for the PIO, DMA, and UDMA transfer rates that are supported by the ATA controller and the ATA device. The results of changing the device’s timings using this function are undefined.

If *Packet->Length* is not set to **EFI_ATA_PASS_THRU_LENGTH_NO_DATA_TRANSFER**, then if **EFI_ATA_PASS_THRU_LENGTH_BYTES** is set in *Packet->Length*, then *Packet->InTransferLength* and *Packet->OutTransferLength* are interpreted as bytes.

If *Packet->Length* is not set to **EFI_ATA_PASS_THRU_LENGTH_NO_DATA_TRANSFER**, then if **EFI_ATA_PASS_THRU_LENGTH_BYTES** is clear in *Packet->Length*, then *Packet->InTransferLength* and *Packet->OutTransferLength* are interpreted as blocks.

If *Packet->Length* is set to **EFI_ATA_PASS_THRU_LENGTH_SECTOR_COUNT**, then the transfer length will be programmed into *Acb->AtaSectorCount*.

If *Packet->Length* is set to **EFI_ATA_PASS_THRU_LENGTH_TPSIU**, then the transfer length will be programmed into the TPSIU.

- For PIO data transfers, the number of sectors to transfer is $2^{(Packet->Length \& \text{EFI_ATA_PASS_THRU_LENGTH_COUNT})}$.

For all commands, the contents of the ATA status block will be returned in *Asb*.

Status Codes Returned

EFI_SUCCESS	The ATA command was sent by the host. For bi-directional commands, <i>InTransferLength</i> bytes were transferred from <i>InDataBuffer</i> . For write and bi-directional commands, <i>OutTransferLength</i> bytes were transferred by <i>OutDataBuffer</i> . See <i>Asb</i> for additional status information.
EFI_BAD_BUFFER_SIZE	The ATA command was not executed. The number of bytes that could be transferred is returned in <i>InTransferLength</i> . For write and bi-directional commands, <i>OutTransferLength</i> bytes were transferred by <i>OutDataBuffer</i> . See <i>Asb</i> for additional status information.
EFI_NOT_READY	The ATA command could not be sent because there are too many ATA commands already queued. The caller may retry again later.
EFI_DEVICE_ERROR	A device error occurred while attempting to send the ATA command. See <i>Asb</i> for additional status information.
EFI_INVALID_PARAMETER	<i>Port</i> , <i>PortMultiplierPort</i> , or the contents of <i>Acb</i> are invalid. The ATA command was not sent, so no additional status information is available.
EFI_UNSUPPORTED	The command described by the ATA command is not supported by the host adapter. The ATA command was not sent, so no additional status information is available.
EFI_TIMEOUT	A timeout occurred while waiting for the ATA command to execute. See <i>Asb</i> for additional status information.

EFI_ATA_PASS_THRU_PROTOCOL.GetNextPort()

Summary

Used to retrieve the list of legal port numbers for ATA devices on an ATA controller. These can either be the list of ports where ATA devices are actually present or the list of legal port numbers for the ATA controller. Regardless, the caller of this function must probe the port number returned to see if an ATA device is actually present at that location on the ATA controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_GET_NEXT_PORT) (
    IN EFI_ATA_PASS_THRU_PROTOCOL *This,
    IN OUT UINT16                  *Port
);
```

Parameters

This

A pointer to the **EFI_ATA_PASS_THRU_PROTOCOL** instance.

Port

On input, a pointer to the port number on the ATA controller. On output, a pointer to the next port number on the ATA controller. An input value of **0xFFFF** retrieves the first port number on the ATA controller.

Description

The **GetNextPort()** function retrieves the port number on an ATA controller. If on input *Port* is **0xFFFF**, then the port number of the first port on the ATA controller is returned in *Port* and **EFI_SUCCESS** is returned.

If *Port* is the port number that was returned on the previous call to **GetNextPort()**, then the port number of the next port on the ATA controller is returned in *Port*, and **EFI_SUCCESS** is returned.

If *Port* is not **0xFFFF** and *Port* was not returned on the previous call to **GetNextPort()**, then **EFI_INVALID_PARAMETER** is returned.

If *Port* is the port number of the last port on the ATA controller, then **EFI_NOT_FOUND** is returned.

Status Codes Returned

EFI_SUCCESS	The next port number on the ATA controller was returned in <i>Port</i> .
EFI_NOT_FOUND	There are no more ports on this ATA controller.
EFI_INVALID_PARAMETER	<i>Port</i> is not 0xFFFF and <i>Port</i> was not returned on a previous call to GetNextPort() .

EFI_ATA_PASS_THRU_PROTOCOL.GetNextDevice()

Summary

Used to retrieve the list of legal port multiplier port numbers for ATA devices on a port of an ATA controller. These can either be the list of port multiplier ports where ATA devices are actually present on port or the list of legal port multiplier ports on that port. Regardless, the caller of this function must probe the port number and port multiplier port number returned to see if an ATA device is actually present.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_ATA_PASS_THRU_GET_NEXT_DEVICE) (
    IN EFI_ATA_PASS_THRU_PROTOCOL *This,
    IN UINT16                      Port,
    IN OUT UINT16                  *PortMultiplierPort
);
```

Parameters

This

A pointer to the **EFI_ATA_PASS_THRU_PROTOCOL** instance.

Port

The port number present on the ATA controller.

PortMultiplierPort

On input, a pointer to the port multiplier port number of an ATA device present on the ATA controller. If on input a *PortMultiplierPort* of **0xFFFF** is specified, then the port multiplier port number of the first ATA device is returned. On output, a pointer to the port multiplier port number of the next ATA device present on an ATA controller.

Description

The **GetNextDevice()** function retrieves the port multiplier port number of an ATA device present on a port of an ATA controller.

If *PortMultiplierPort* points to a port multiplier port number value that was returned on a previous call to **GetNextDevice()**, then the port multiplier port number of the next ATA device on the port of the ATA controller is returned in *PortMultiplierPort*, and **EFI_SUCCESS** is returned.

If *PortMultiplierPort* points to **0xFFFF**, then the port multiplier port number of the first ATA device on port of the ATA controller is returned in *PortMultiplierPort* and **EFI_SUCCESS** is returned.

If *PortMultiplierPort* is not **0xFFFF** and the value pointed to by *PortMultiplierPort* was not returned on a previous call to **GetNextDevice()**, then **EFI_INVALID_PARAMETER** is returned.

If *PortMultiplierPort* is the port multiplier port number of the last ATA device on the port of the ATA controller, then **EFI_NOT_FOUND** is returned.

Status Codes Returned

EFI_SUCCESS	The port multiplier port number of the next ATA device on the port of the ATA controller was returned in <i>PortMultiplierPort</i> .
EFI_NOT_FOUND	There are no more ATA devices on this port of the ATA controller.
EFI_INVALID_PARAMETER	<i>PortMultiplierPort</i> is not 0xFFFF , and <i>PortMultiplierPort</i> was not returned on a previous call to GetNextDevice() .

EFI_ATA_PASS_THRU_PROTOCOL.BuildDevicePath()

Summary

Used to allocate and build a device path node for an ATA device on an ATA controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_BUILD_DEVICE_PATH) (
    IN      EFI_ATA_PASS_THRU_PROTOCOL *This,
    IN      UINT16                      Port,
    IN      UINT16                      PortMultiplierPort,
    IN OUT  EFI_DEVICE_PATH_PROTOCOL **DevicePath
);
```

Parameters

This

A pointer to the **EFI_ATA_PASS_THRU_PROTOCOL** instance.

Port

Port specifies the port number of the ATA device for which a device path node is to be allocated and built.

PortMultiplierPort

The port multiplier port number of the ATA device for which a device path node is to be allocated and built. If there is no port multiplier, then specify 0xFFFF.

DevicePath

A pointer to a single device path node that describes the ATA device specified by *Port* and *PortMultiplierPort*. This function is responsible for allocating the buffer *DevicePath* with the boot service **AllocatePool()**. It is the caller's responsibility to free *DevicePath* when the caller is finished with *DevicePath*.

Description

The **BuildDevicePath()** function allocates and builds a single device node for the ATA device specified by *Port* and *PortMultiplierPort*. If the ATA device specified by *Port* and *PortMultiplierPort* is not present on the ATA controller, then **EFI_NOT_FOUND** is returned. If *DevicePath* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If there are not enough resources to allocate the device path node, then **EFI_OUT_OF_RESOURCES** is returned.

Otherwise, *DevicePath* is allocated with the boot service **AllocatePool()**, the contents of *DevicePath* are initialized to describe the ATA device specified by *Port* and *PortMultiplierPort*, and **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The device path node that describes the ATA device specified by <i>Port</i> and <i>PortMultiplierPort</i> was allocated and returned in <i>DevicePath</i> .
EFI_NOT_FOUND	The ATA device specified by <i>Port</i> and <i>PortMultiplierPort</i> does not exist on the ATA controller.
EFI_INVALID_PARAMETER	<i>DevicePath</i> is NULL .
EFI_OUT_OF_RESOURCES	There are not enough resources to allocate <i>DevicePath</i> .

EFI_ATA_PASS_THRU_PROTOCOL.GetDevice()

Summary

Used to translate a device path node to a port number and port multiplier port number.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_GET_DEVICE) (
    IN  EFI_ATA_PASS_THRU_PROTOCOL *This,
    IN  EFI_DEVICE_PATH_PROTOCOL  *DevicePath,
    OUT UINT16                     *Port,
    OUT UINT16                     *PortMultiplierPort
);
```

Parameters

This

A pointer to the **EFI_ATA_PASS_THRU_PROTOCOL** instance.

DevicePath

A pointer to the device path node that describes an ATA device on the ATA controller.

Port

On return, points to the port number of an ATA device on the ATA controller.

PortMultiplierPort

On return, points to the port multiplier port number of an ATA device on the ATA controller.

Description

The **GetDevice()** function determines the port and port multiplier port number associated with the ATA device described by *DevicePath*. If *DevicePath* is a device path node type that the ATA Pass Thru driver supports, then the ATA Pass Thru driver will attempt to translate the contents *DevicePath* into a port number and port multiplier port number.

If this translation is successful, then that port number and port multiplier port number are returned in *Port* and *PortMultiplierPort*, and **EFI_SUCCESS** is returned.

If *DevicePath*, *Port*, or *PortMultiplierPort* are **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *DevicePath* is not a device path node type that the ATA Pass Thru driver supports, then **EFI_UNSUPPORTED** is returned.

If *DevicePath* is a device path node type that the ATA Pass Thru driver supports, but there is not a valid translation from *DevicePath* to a port number and port multiplier port number, then **EFI_NOT_FOUND** is returned.

Status Codes Returned

EFI_SUCCESS	<i>DevicePath</i> was successfully translated to a port number and port multiplier port number, and they were returned in <i>Port</i> and <i>PortMultiplierPort</i> .
EFI_INVALID_PARAMETER	<i>DevicePath</i> is NULL .
EFI_INVALID_PARAMETER	<i>Port</i> is NULL .
EFI_INVALID_PARAMETER	<i>PortMultiplierPort</i> is NULL .
EFI_UNSUPPORTED	This driver does not support the device path node type in <i>DevicePath</i> .
EFI_NOT_FOUND	A valid translation from <i>DevicePath</i> to a port number and port multiplier port number does not exist.

EFI_ATA_PASS_THRU_PROTOCOL.ResetPort()

Summary

Resets a specific port on the ATA controller. This operation also resets all the ATA devices connected to the port.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_ATA_PASS_THRU_RESET_PORT) (
    IN EFI_ATA_PASS_THRU_PROTOCOL *This,
    IN UINT16                      Port
);
```

Parameters

This

A pointer to the **EFI_ATA_PASS_THRU_PROTOCOL** instance.

Port

The port number on the ATA controller.

Description

The **ResetChannel ()** function resets an a specific port on an ATA controller. This operation resets all the ATA devices connected to that port. If this ATA controller does not support a reset port operation, then **EFI_UNSUPPORTED** is returned.

If a device error occurs while executing that port reset operation, then **EFI_DEVICE_ERROR** is returned.

If a timeout occurs during the execution of the port reset operation, then **EFI_TIMEOUT** is returned. If the port reset operation is completed, then **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The ATA controller port was reset.
EFI_UNSUPPORTED	The ATA controller does not support a port reset operation.
EFI_DEVICE_ERROR	A device error occurred while attempting to reset the ATA port.
EFI_TIMEOUT	A timeout occurred while attempting to reset the ATA port.

EFI_ATA_PASS_THRU_PROTOCOL.ResetDevice()

Summary

Resets an ATA device that is connected to an ATA controller.

Prototype

```

typedef
EFI_STATUS
(EFI_API *EFI_ATA_PASS_THRU_RESET_DEVICE) (
    IN EFI_ATA_PASS_THRU_PROTOCOL *This,
    IN UINT16                      Port,
    IN UINT16                      PortMultiplierPort
);

```

Parameters

This

A pointer to the **EFI_ATA_PASS_THRU_PROTOCOL** instance.

Port

Port represents the port number of the ATA device to be reset.

PortMultiplierPort

The port multiplier port number of the ATA device to reset. If there is no port multiplier, then specify 0xFFFF.

Description

The **ResetDevice()** function resets the ATA device specified by *Port* and *PortMultiplierPort*. If this ATA controller does not support a device reset operation, then **EFI_UNSUPPORTED** is returned.

If *Port* or *PortMultiplierPort* are not in a valid range for this ATA controller, then **EFI_INVALID_PARAMETER** is returned.

If a device error occurs while executing that device reset operation, then **EFI_DEVICE_ERROR** is returned.

If a timeout occurs during the execution of the device reset operation, then **EFI_TIMEOUT** is returned.

If the device reset operation is completed, then **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The ATA device specified by <i>Port</i> and <i>PortMultiplierPort</i> was reset
EFI_UNSUPPORTED	The ATA controller does not support a device reset operation.
EFI_INVALID_PARAMETER	<i>Port</i> or <i>PortMultiplierPort</i> are invalid.
EFI_DEVICE_ERROR	A device error occurred while attempting to reset the ATA device specified by <i>Port</i> and <i>PortMultiplierPort</i> .
EFI_TIMEOUT	A timeout occurred while attempting to reset the ATA device specified by <i>Port</i> and <i>PortMultiplierPort</i> .

12.14 Storage Security Command Protocol

This section defines the storage security command protocol. This protocol is used to abstract mass storage devices to allow code running in the EFI boot services environment to send security protocol commands to mass storage devices without specific knowledge of the type of device or controller that manages the device. Functions are defined to send or retrieve security protocol defined data to and from mass storage devices. This protocol shall be supported on all physical and logical storage devices supporting the **EFI_BLOCK_IO_PROTOCOL** in the EFI boot services environment and one of the following command sets (or their alternative) at the bus level:

- TRUSTED SEND/RECEIVE commands of the ATA8-ACS command set or its successor
- SECURITY PROTOCOL IN/OUT commands of the SPC-4 command set or its successor.

EFI_STORAGE_SECURITY_COMMAND_PROTOCOL

Summary

This protocol provides ability to send security protocol commands to mass storage devices.

GUID

```
#define EFI_STORAGE_SECURITY_COMMAND_PROTOCOL_GUID \
    {0xc88b0b6d, 0x0dfc, 0x49a7, \
     {0x9c, 0xb4, 0x49, 0x7, 0x4b, 0x4c, 0x3a, 0x78}}
```

Protocol Interface Structure

```
typedef struct _EFI_STORAGE_SECURITY_COMMAND_PROTOCOL {
    EFI_STORAGE_SECURITY_RECEIVE_DATA    ReceiveData;
    EFI_STORAGE_SECURITY_SEND_DATA       SendData;
} EFI_STORAGE_SECURITY_COMMAND_PROTOCOL;
```

Parameters

ReceiveData

Issues a security protocol command to the requested device that receives data and/or the result of one or more commands sent by *SendData*. See the **ReceiveData()** function description.

SendData

Issues a security protocol command to the requested device. See the **SendData ()** function description.

Description

The **EFI_STORAGE_SECURITY_COMMAND_PROTOCOL** is used to send security protocol commands to a mass storage device. Two types of security protocol commands are supported. *SendData* sends a command with data to a device. *ReceiveData* sends a command that receives data and/or the result of one or more commands sent by *SendData*.

The security protocol command formats supported shall be based on the definition of the SECURITY PROTOCOL IN and SECURITY PROTOCOL OUT commands defined in SPC-4. If the device uses the SCSI command set, no translation is needed in the firmware and the firmware can package the parameters into a SECURITY PROTOCOL IN or SECURITY PROTOCOL OUT command and send the command to the device. If the device uses a non-SCSI command set, the firmware shall map the command and data payload to the corresponding command and payload format defined in the non-SCSI command set (for example, TRUSTED RECEIVE and TRUSTED SEND in ATA8-ACS).

The firmware shall automatically add an **EFI_STORAGE_SECURITY_COMMAND_PROTOCOL** for any storage devices detected during system boot that support SPC-4, ATA8-ACS or their successors.

EFI_STORAGE_SECURITY_COMMAND_PROTOCOL.ReceiveData()

Summary

Send a security protocol command to a device that receives data and/or the result of one or more commands sent by *SendData*.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_STORAGE_SECURITY_RECEIVE_DATA) (
    IN EFI_STORAGE_SECURITY_COMMAND_PROTOCOL *This,
    IN UINT32 MediaId,
    IN UINT64 Timeout,
    IN UINT8 SecurityProtocol,
    IN UINT16 SecurityProtocolSpecificData,
    IN UINTN PayloadBufferSize,
    OUT VOID *PayloadBuffer,
    OUT UINTN *PayloadTransferSize
);
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_STORAGE_SECURITY_COMMAND_PROTOCOL is defined in the EFI_STORAGE_SECURITY_COMMAND_PROTOCOL description.
<i>MediaId</i>	ID of the medium to receive data from.
<i>Timeout</i>	The timeout, in 100ns units, to use for the execution of the security protocol command. A <i>Timeout</i> value of 0 means that this function will wait indefinitely for the security protocol command to execute. If <i>Timeout</i> is greater than zero, then this function will return EFI_TIMEOUT if the time required to execute the receive data command is greater than <i>Timeout</i> .
<i>SecurityProtocolId</i>	The value of the “Security Protocol” parameter of the security protocol command to be sent.
<i>SecurityProtocolSpecificData</i>	The value of the “Security Protocol Specific” parameter of the security protocol command to be sent. This value is in big-endian format.
<i>PayloadBufferSize</i>	Size in bytes of the payload data buffer.
<i>PayloadBuffer</i>	A pointer to a destination buffer to store the security protocol command specific payload data for the security protocol command. The caller is responsible for having either implicit or explicit ownership of the buffer.

PayloadTransferSize

A pointer to a buffer to store the size in bytes of the data written to the payload data buffer.

Description

The *ReceiveData* function sends a security protocol command to the given *MediaId*. The security protocol command sent is defined by *SecurityProtocolId* and contains the security protocol specific data *SecurityProtocolSpecificData*. The function returns the data from the security protocol command in *PayloadBuffer*.

For devices supporting the SCSI command set, the security protocol command is sent using the SECURITY PROTOCOL IN command defined in SPC-4.

For devices supporting the ATA command set, the security protocol command is sent using one of the TRUSTED RECEIVE commands defined in ATA8-ACS if *PayloadBufferSize* is non-zero. If the *PayloadBufferSize* is zero, the security protocol command is sent using the Trusted Non-Data command defined in ATA8-ACS.

If *PayloadBufferSize* is too small to store the available data from the security protocol command, the function shall copy *PayloadBufferSize* bytes into the *PayloadBuffer* and return **EFI_WARN_BUFFER_TOO_SMALL**.

If *PayloadBuffer* or *PayloadTransferSize* is **NULL** and *PayloadBufferSize* is non-zero, the function shall return **EFI_INVALID_PARAMETER**.

If the given *MediaId* does not support security protocol commands, the function shall return **EFI_UNSUPPORTED**. If there is no media in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID for the current media in the device, the function returns **EFI_MEDIA_CHANGED**.

If the security protocol fails to complete within the *Timeout* period, the function shall return **EFI_TIMEOUT**.

If the security protocol command completes without an error, the function shall return **EFI_SUCCESS**. If the security protocol command completes with an error, the function shall return **EFI_DEVICE_ERROR**.

Status Codes Returned

EFI_SUCCESS	The security protocol command completed successfully.
EFI_WARN_BUFFER_TOO_SMALL	The <i>PayloadBufferSize</i> was too small to store the available data from the device. The <i>PayloadBuffer</i> contains the truncated data.
EFI_UNSUPPORTED	The given <i>MediaId</i> does not support security protocol commands.
EFI_DEVICE_ERROR	The security protocol command completed with an error.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.
EFI_INVALID_PARAMETER	The <i>PayloadBuffer</i> or <i>PayloadTransferSize</i> is NULL and <i>PayloadBufferSize</i> is non-zero.
EFI_TIMEOUT	A timeout occurred while waiting for the security protocol command to execute.

EFI_STORAGE_SECURITY_COMMAND_PROTOCOL.SendData()

Summary

Send a security protocol command to a device.

Prototype

```
typedef
    EFI_STATUS
    (EFIAPI *EFI_STORAGE_SECURITY_SEND_DATA) (
        IN EFI_STORAGE_SECURITY_COMMAND_PROTOCOL *This,
        IN UINT32                               MediaId,
        IN UINT64                               Timeout,
        IN UINT8                               SecurityProtocolId,
        IN UINT16                              SecurityProtocolSpecificData,
        IN UINTN                               PayloadBufferSize,
        IN VOID                                *PayloadBuffer
    );
```

Parameters

<i>This</i>	Indicates a pointer to the calling context. Type EFI_STORAGE_SECURITY_COMMAND_PROTOCOL is defined in the EFI_STORAGE_SECURITY_COMMAND_PROTOCOL description.
<i>MediaId</i>	ID of the medium to send data to.
<i>Timeout</i>	The timeout, in 100ns units, to use for the execution of the security protocol command. A <i>Timeout</i> value of 0 means that this function will wait indefinitely for the security protocol command to execute. If <i>Timeout</i> is greater than zero, then this function will return EFI_TIMEOUT if the time required to execute the receive data command is greater than <i>Timeout</i> .
<i>SecurityProtocolId</i>	The value of the “Security Protocol” parameter of the security protocol command to be sent.
<i>SecurityProtocolSpecificData</i>	The value of the “Security Protocol Specific” parameter of the security protocol command to be sent.
<i>PayloadBufferSize</i>	Size in bytes of the payload data buffer.
<i>PayloadBuffer</i>	A pointer to a buffer containing the security protocol command specific payload data for the security protocol command.

Description

The *SendData* function sends a security protocol command containing the payload *PayloadBuffer* to the given *MediaId*. The security protocol command sent is defined by *SecurityProtocolId* and contains the security protocol specific data

SecurityProtocolSpecificData. If the underlying protocol command requires a specific padding for the command payload, the *SendData* function shall add padding bytes to the command payload to satisfy the padding requirements.

For devices supporting the SCSI command set, the security protocol command is sent using the SECURITY PROTOCOL OUT command defined in SPC-4.

For devices supporting the ATA command set, the security protocol command is sent using one of the TRUSTED SEND commands defined in ATA8-ACS if *PayloadBufferSize* is non-zero. If the *PayloadBufferSize* is zero, the security protocol command is sent using the Trusted Non-Data command defined in ATA8-ACS.

If *PayloadBuffer* is **NULL** and *PayloadBufferSize* is non-zero, the function shall return **EFI_INVALID_PARAMETER**.

If the given *MediaId* does not support security protocol commands, the function shall return **EFI_UNSUPPORTED**. If there is no media in the device, the function returns **EFI_NO_MEDIA**. If the *MediaId* is not the ID for the current media in the device, the function returns **EFI_MEDIA_CHANGED**.

If the security protocol fails to complete within the *Timeout* period, the function shall return **EFI_TIMEOUT**.

If the security protocol command completes without an error, the function shall return **EFI_SUCCESS**. If the security protocol command completes with an error, the function shall return **EFI_DEVICE_ERROR**.

Status Codes Returned

EFI_SUCCESS	The security protocol command completed successfully.
EFI_UNSUPPORTED	The given <i>MediaId</i> does not support security protocol commands.
EFI_DEVICE_ERROR	The security protocol command completed with an error.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The <i>MediaId</i> is not for the current media.
EFI_INVALID_PARAMETER	The <i>PayloadBuffer</i> is NULL and <i>PayloadBufferSize</i> is non-zero.
EFI_TIMEOUT	A timeout occurred while waiting for the security protocol command to execute.

12.15 NVM Express Pass Through Protocol

EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL

This section provides a detailed description of the **EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL**.

Summary

This protocol provides services that allow NVM Express commands to be sent to an NVM Express controller or to a specific namespace in a NVM Express controller. This protocol interface is optimized for storage.

GUID

```
#define EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL_GUID \
    { 0x52c78312, 0x8edc, 0x4233, \
      { 0x98, 0xf2, 0x1a, 0x1a, 0xa5, 0xe3, 0x88, 0xa5 } };
```

Protocol Interface Structure

```
typedef struct _EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL {
    EFI_NVM_EXPRESS_PASS_THRU_MODE           *Mode;
    EFI_NVM_EXPRESS_PASS_THRU_PASSTHRU      PassThru;
    EFI_NVM_EXPRESS_PASS_THRU_GET_NEXT_NAMESPACE GetNextNamespace;
    EFI_NVM_EXPRESS_PASS_THRU_BUILD_DEVICE_PATH BuildDevicePath;
    EFI_NVM_EXPRESS_PASS_THRU_GET_NAMESPACE  GetNamespace;
} EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL;
```

Parameters

<i>Mode</i>	A pointer to the EFI_NVM_EXPRESS_PASS_THRU_MODE data for this NVM Express controller. EFI_NVM_EXPRESS_PASS_THRU_MODE is defined in “Related Definitions” below.
<i>PassThru</i>	Sends an NVM Express Command Packet to an NVM Express controller. See the EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.PassThru() function description.
<i>GetNextNamespace</i>	Retrieves the next namespace ID for this NVM Express controller. See the EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNextNamespace() function description.
<i>BuildDevicePath</i>	Allocates and builds a device path node for a namespace on an NVM Express controller. See the EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.BuildDevicePath() function description.
<i>GetNamespace</i>	Translates a device path node to a namespace ID. See the EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNamespace() function description.

The following data values in the **EFI_NVM_EXPRESS_PASS_THRU_MODE** interface are read-only.

<i>Attributes</i>	Additional information on the attributes of the NVM Express controller. See “Related Definitions” below for the list of possible attributes.
<i>IoAlign</i>	Supplies the alignment requirement for any buffer used in a data transfer. <i>IoAlign</i> values of 0 and 1 mean that the buffer can be

placed anywhere in memory. Otherwise, *IoAlign* must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by *IoAlign* with no remainder.

NvmeVersion

Indicates the version of the NVM Express specification that the controller implementation supports. The format of this field is defined in the Version field of the Controller Registers in the *NVM Express Specification*.

Related Definitions

```
typedef struct {
    UINT32 Attributes;
    UINT32 IoAlign;
    UINT32 NvmeVersion;
} EFI_NVM_EXPRESS_PASS_THRU_MODE;

#define EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_PHYSICAL
0x0001
#define EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL
0x0002
#define EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_NONBLOCKIO 0x0004
#define EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_CMD_SET_NVM 0x0008
```

EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_PHYSICAL

If this bit is set, then the **EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL** interface is for directly addressable namespaces.

EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL

If this bit is set, then the **EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL** interface is for a single volume logical namespace comprised of multiple namespaces.

EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_NONBLOCKIO

If this bit is set, then the **EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL** interface supports non-blocking I/O.

EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_CMD_SET_NVM

If this bit is set, then the **EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL** interface supports NVM command set.

Description

The **EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL** provides information about an NVM Express controller and the ability to send NVM Express commands to an NVM Express controller or to a specific namespace in a NVM Express controller.

The printable name for the NVM Express controller can be provided through the **EFI_COMPONENT_NAME_PROTOCOL** and the **EFI_COMPONENT_NAME2_PROTOCOL** for multiple languages.

The *Attributes* field of the **EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL** interface tells if the interface is for physical NVM Express controllers or logical NVM Express controllers. Drivers

for non-RAID NVM Express controllers will set both the **EFI_NVME_EXPRESS_PASS_THRU_ATTRIBUTES_PHYSICAL**, and the **EFI_NVME_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL** bits.

Drivers for RAID controllers that allow access to the physical controllers and logical controllers will produce two **EFI_NVME_EXPRESS_PASS_THRU_PROTOCOL** interfaces: one with just the **EFI_NVME_EXPRESS_PASS_THRU_ATTRIBUTES_PHYSICAL** bit set and another with just the **EFI_NVME_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL** bit set. One interface can be used to access the physical controllers attached to the RAID controller, and the other can be used to access the logical controllers attached to the RAID controller for its current configuration.

Drivers for RAID controllers that do not allow access to the physical controllers will produce one **EFI_NVME_EXPRESS_PASS_THRU_PROTOCOL** interface with just the **EFI_NVME_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL** bit set. The interface for logical controllers can also be used by a file system driver to mount the RAID volumes. An **EFI_NVME_EXPRESS_PASS_THRU_PROTOCOL** with neither **EFI_NVME_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL** nor **EFI_NVME_EXPRESS_PASS_THRU_ATTRIBUTES_PHYSICAL** set is an illegal configuration.

The *Attributes* field also contains the **EFI_NVME_EXPRESS_PASS_THRU_ATTRIBUTES_NONBLOCKIO** bit. All **EFI_NVME_EXPRESS_PASS_THRU_PROTOCOL** interfaces must support blocking I/O. If this bit is set, then the interface supports both blocking I/O and non-blocking I/O.

The *Attributes* field also contains the **EFI_NVME_EXPRESS_PASS_THRU_ATTRIBUTES_CMD_SET_NVME** bit. If this bit is set, the controller supports the NVM Express command set.

Each **EFI_NVME_EXPRESS_PASS_THRU_PROTOCOL** instance must have an associated device path. Typically this will have an *ACPI* device path node and a *PCI* device path node, although variation will exist.

EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.PassThru()

Summary

Sends an NVM Express Command Packet to an NVM Express controller or namespace. This function supports both blocking I/O and non-blocking I/O. The blocking I/O functionality is required, and the non-blocking I/O functionality is optional.

Prototype

```
typedef EFI_STATUS
(EFI_API *EFI_NVM_EXPRESS_PASS_THRU_PASSTHRU) (
    IN EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL      *This,
    IN UINT32                                  NamespaceId,
    IN OUT EFI_NVM_EXPRESS_PASS_THRU_COMMAND_PACKET *Packet,
    IN EFI_EVENT                               Event OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL instance. Type EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL is defined in Section 12.15 , above.
<i>NamespaceId</i>	A 32 bit namespace ID as defined in the NVMe specification to which the NVM Express Command Packet will be sent. A value of 0 denotes the NVM Express controller, a value of all 0xFF 's (all bytes are 0xFF) in the namespace ID specifies that the command packet should be sent to all valid namespaces.
<i>Packet</i>	A pointer to the NVM Express Command Packet. See “Related Definitions” below for a description of EFI_NVM_EXPRESS_PASS_THRU_COMMAND_PACKET .
<i>Event</i>	If non-blocking I/O is not supported then <i>Event</i> is ignored, and blocking I/O is performed. If <i>Event</i> is NULL, then blocking I/O is performed. If <i>Event</i> is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and <i>Event</i> will be signaled when the NVM Express Command Packet completes.

Related Definitions

```
typedef struct {
    UINT64                CommandTimeout;
    VOID                  *TransferBuffer OPTIONAL;
    UINT32                TransferLength OPTIONAL;
    VOID                  *MetaDataBuffer OPTIONAL;
    UINT32                MetadataLength OPTIONAL;
    UINT8                 QueueType;
    EFI_NVM_EXPRESS_COMMAND *NvmeCmd;
    EFI_NVM_EXPRESS_COMPLETION *NvmeCompletion;
} EFI_NVM_EXPRESS_PASS_THRU_COMMAND_PACKET;
```

CommandTimeout The timeout in 100 ns units to use for the execution of this NVM Express Command Packet. A *Timeout* value of 0 means that this function will wait indefinitely for the command to execute. If *Timeout* is greater than zero, then this function will return **EFI_TIMEOUT** if the time required to execute the NVM Express command is greater than *Timeout*.

TransferBuffer A pointer to the data buffer to transfer between the host and the NVM Express controller for read, write, and bi-directional commands. For all write and non-data commands where *TransferLength* is 0 this field is optional and may be NULL. If this field is not NULL, then it must be aligned on the boundary specified by the *IoAlign* field in the **EFI_NVM_EXPRESS_PASS_THRU_MODE** structure.

TransferLength On input, the size in bytes of *TransferBuffer*. On output, the number of bytes transferred to or from the NVM Express controller or namespace.

MetaDataBuffer A pointer to the optional metadata buffer to transfer between the host and the NVM Express controller. For all commands where no metadata is transferred between the host and the controller, this field is optional and may be NULL. If this field is not NULL, then it must be aligned on the boundary specified by the *IoAlign* field in the **EFI_NVM_EXPRESS_PASS_THRU_MODE** structure.

MetadataLength On input, the size in bytes of *MetaDataBuffer*. On output, the number of bytes transferred to or from the NVM Express controller or namespace.

QueueType The type of the queue that the NVMe command should be posted to. A value of 0 indicates it should be posted to the Admin Submission Queue. A value of 1 indicates it should be posted to an I/O Submission Queue.

NvmeCmd A pointer to an NVM Express Command Packet.

NvmeCompletion The raw NVM Express completion queue entry as defined in the *NVM Express Specification*.

Description

The **PassThru ()** function sends the NVM Express Command Packet specified by *Packet* to the NVM Express controller. If the driver supports non-blocking I/O and *Event* is not NULL, then the driver will return immediately after the command is sent to the selected controller, and will later signal Event when the command has completed.

If the driver supports non-blocking I/O and *Event* is NULL, then the driver will send the command to the selected device and block until it is complete.

If the driver does not support non-blocking I/O, then the *Event* parameter is ignored, and the driver will send the command to the selected device and block until it is complete.

If *Packet* is successfully sent to the NVM Express controller, then **EFI_SUCCESS** is returned.

If a device error occurs while sending the *Packet*, then **EFI_DEVICE_ERROR** is returned.

If a timeout occurs during the execution of *Packet*, then **EFI_TIMEOUT** is returned.

If *NamespaceId* is invalid for the NVM Express controller, then **EFI_INVALID_PARAMETER** is returned.

If *TransferBuffer* or *MetadataBuffer* do not meet the alignment requirement specified by the *IoAlign* field of the **EFI_NVM_EXPRESS_PASS_THRU_MODE** structure, then **EFI_INVALID_PARAMETER** is returned. If the *QueueType* is not 0 (Admin Submission Queue) or 1 (I/O Submission Queue), then **EFI_INVALID_PARAMETER** is returned. If any of the other fields of *Packet* are invalid, then **EFI_INVALID_PARAMETER** is returned.

If the data buffer described by *TransferBuffer* and *TransferLength* is too big to be transferred in a single command, then no data is transferred and **EFI_BAD_BUFFER_SIZE** is returned. The number of bytes that can be transferred in a single command are returned in *TransferLength*.

If **EFI_SUCCESS**, **EFI_DEVICE_ERROR**, or **EFI_TIMEOUT** is returned, then the caller must examine the *NvmeCompletion* field in *Packet*.

If non-blocking I/O is being used, then the *NvmeCompletion* field in *Packet* will not be valid until the *Event* associated with *Packet* is signaled.

If **EFI_NOT_READY**, **EFI_INVALID_PARAMETER**, **EFI_BAD_BUFFER_SIZE**, or **EFI_UNSUPPORTED** is returned, then *Packet* was never sent, so the *NvmeCompletion* field in *Packet* is not valid. If non-blocking I/O is being used, the *Event* associated with *Packet* will not be signaled.

Status Codes Returned

EFI_SUCCESS	The NVM Express Command Packet was sent by the host. <i>TransferLength</i> bytes were transferred to or from <i>TransferBuffer</i> . See <i>NvmeCompletion</i> (above) for additional status information.
EFI_BAD_BUFFER_SIZE	The NVM Express Command Packet was not executed. The number of bytes that could be transferred is returned in <i>TransferLength</i> .
EFI_NOT_READY	The NVM Express Command Packet could not be sent because the controller is not ready. The caller may retry again later.
EFI_DEVICE_ERROR	A device error occurred while attempting to send the NVM Express Command Packet. See <i>NvmeCompletion</i> (above) for additional status information.
EFI_INVALID_PARAMETER	<i>NamespaceId</i> or the contents of EFI_NVM_EXPRESS_PASS_THRU_COMMAND_PACKET are invalid. The NVM Express Command Packet was not sent, so no additional status information is available.
EFI_UNSUPPORTED	The command described by the NVM Express Command Packet is not supported by the NVM Express controller. The NVM Express Command Packet was not sent so no additional status information is available.
EFI_TIMEOUT	A timeout occurred while waiting for the NVM Express Command Packet to execute. See <i>NvmeCompletion</i> (above) for additional status information.

EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNextNamespace()

Summary

Used to retrieve the next namespace ID for this NVM Express controller.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_NVM_EXPRESS_PASS_THRU_GET_NEXT_NAMESPACE) (
    IN EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL *This,
    IN OUT UINT32 *NamespaceId
);
```

Parameters

<i>This</i>	A pointer to the EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL instance.
<i>NamespaceId</i>	On input, a pointer to a valid namespace ID on this NVM Express controller or a pointer to the value 0xFFFFFFFF . A pointer to the value 0xFFFFFFFF retrieves the first valid namespace ID on this NVM Express controller.

Description

The **EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNextNamespace()** function retrieves the next valid namespace ID on this NVM Express controller. If on input the value pointed to by *NamespaceId* is **0xFFFFFFFF**, then the first valid namespace ID defined on the NVM Express controller is returned in the location pointed to by *NamespaceId* and a status of **EFI_SUCCESS** is returned.

If on input the value pointed to by *NamespaceId* is an invalid namespace ID other than **0xFFFFFFFF**, then **EFI_INVALID_PARAMETER** is returned.

If on input the value pointed to by *NamespaceId* is a valid namespace ID, then the next valid namespace ID on the NVM Express controller is returned in the location pointed to by *NamespaceId*, and **EFI_SUCCESS** is returned.

If the value pointed to by *NamespaceId* is the namespace ID of the last namespace on the NVM Express controller, then **EFI_NOT_FOUND** is returned.

Status Codes Returned

EFI_SUCCESS	The Namespace ID of the next <i>Namespace</i> was returned.
EFI_NOT_FOUND	There are no more namespaces defined on this controller.
EFI_INVALID_PARAMETER	<i>NamespaceId</i> is an invalid value other than 0xFFFFFFFF .

EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.BuildDevicePath()

Summary

Used to allocate and build a device path node for an NVM Express namespace on an NVM Express controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_NVM_EXPRESS_PASS_THRU_BUILD_DEVICE_PATH) (
    IN EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL *This,
    IN UINT32                               NamespaceId,
    IN OUT EFI_DEVICE_PATH_PROTOCOL        **DevicePath
);
```

Parameters

This	A pointer to the EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL instance. Type EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL is defined in Section 12.15 .
NamespaceId	The NVM Express namespace ID for which a device path node is to be allocated and built.
DevicePath	A pointer to a single device path node that describes the NVM Express namespace specified by <i>NamespaceId</i> . This function is responsible for allocating the buffer <i>DevicePath</i> with the boot service AllocatePool() . It is the caller's responsibility to free <i>DevicePath</i> when the caller is finished with <i>DevicePath</i> .

Description

The **EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.BuildDevicePath()** function allocates and builds a single device path node for the NVM Express namespace specified by *NamespaceId*. If the *NamespaceId* is not valid, then **EFI_NOT_FOUND** is returned. If *DevicePath* is NULL, then **EFI_INVALID_PARAMETER** is returned. If there are not enough resources to allocate the device path node, then **EFI_OUT_OF_RESOURCES** is returned. Otherwise, *DevicePath* is allocated with the boot service **AllocatePool()**, the contents of *DevicePath* are initialized to describe the NVM Express namespace specified by *NamespaceId*, and **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The device path node that describes the NVM Express namespace specified by <i>NamespaceId</i> was allocated and returned in <i>DevicePath</i> .
EFI_NOT_FOUND	The <i>NamespaceId</i> is not valid.
EFI_INVALID_PARAMETER	<i>DevicePath</i> is NULL .

EFI_OUT_OF_RESOURCES	There are not enough resources to allocate the <i>DevicePath</i> node.
----------------------	--

EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNamespace()

Summary

Used to translate a device path node to a namespace ID.

Prototype

```

typedef
EFI_STATUS
(EFI_API *EFI_NVM_EXPRESS_PASS_THRU_GET_NAMESPACE) (
IN EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL *This,
IN EFI_DEVICE_PATH_PROTOCOL          *DevicePath,
OUT UINT32                            *NamespaceId
);

```

Parameters

<i>This</i>	A pointer to the EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL instance. Type EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL is defined in Section 12.15 .
<i>DevicePath</i>	A pointer to the device path node that describes an NVM Express namespace on the NVM Express controller.
<i>NamespaceId</i>	The NVM Express namespace ID contained in the device path node.

Description

The **EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNamespace()** function determines the namespace ID associated with the namespace described by *DevicePath*. If *DevicePath* is a device path node type that the NVM Express Pass Thru driver supports, then the NVM Express Pass Thru driver will attempt to translate the contents *DevicePath* into a namespace ID. If this translation is successful, then that namespace ID is returned in *NamespaceId*, and **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_INVALID_PARAMETER	If <i>DevicePath</i> or <i>NamespaceId</i> are NULL , then EFI_INVALID_PARAMETER is returned.
EFI_UNSUPPORTED	If <i>DevicePath</i> is not a device path node type that the NVM Express Pass Thru driver supports, then EFI_UNSUPPORTED is returned.
EFI_NOT_FOUND	If <i>DevicePath</i> is a device path node type that the NVM Express Pass Thru driver supports, but there is not a valid translation from <i>DevicePath</i> to a namespace ID, then EFI_NOT_FOUND is returned.

12.16 SD MMC Pass Thru Protocol

EFI_SD_MMC_PASS_THRU_PROTOCOL

This section provides a detailed description of the **EFI_SD_MMC_PASS_THRU_PROTOCOL**.

The protocol provides services that allow SD/eMMC commands to be sent to an SD/eMMC controller. All interfaces and definitions from this section apply equally to SD and eMMC controllers.

For the sake of brevity, the rest of this section refers only to SD devices and controllers and does not specifically mention eMMC devices and controllers.

GUID

```
#define EFI_SD_MMC_PASS_THRU_PROTOCOL_GUID \
    { 0x716ef0d9, 0xff83, 0x4f69, \
      { 0x81, 0xe9, 0x51, 0x8b, 0xd3, 0x9a, 0x8e, 0x70 } }
```

Protocol Interface Structure

```
typedef struct _EFI_SD_MMC_PASS_THRU_PROTOCOL {
    UINTN                                     IoAlign
    EFI_SD_MMC_PASS_THRU_PASSTHRU           PassThru;
    EFI_SD_MMC_PASS_THRU_GET_NEXT_SLOT      GetNextSlot;
    EFI_SD_MMC_PASS_THRU_BUILD_DEVICE_PATH  BuildDevicePath;
    EFI_SD_MMC_PASS_THRU_GET_SLOT_NUMBER    GetSlotNumber;
    EFI_SD_MMC_PASS_THRU_RESET_DEVICE       ResetDevice;
} EFI_SD_MMC_PASS_THRU_PROTOCOL;
```

Parameters

IoAlign

Supplies the alignment requirement for any buffer used in a data transfer. *IoAlign* values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, *IoAlign* must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by *IoAlign* with no remainder.

PassThru

Sends SD command to the SD controller. See the **PassThru()** function description.

Unified Extensible Firmware Interface Specification

<i>GetNextSlot</i>	Retrieves a next slot on an SD controller. See the GetNextSlot() function description.
<i>BuildDevicePath</i>	Allocates and builds a device path node for an SD card on the SD controller. See the BuildDevicePath() function description.
<i>GetSlotNumber</i>	Retrieves the SD card slot number based on the input device path. See the GetSlotNumber() function description.
<i>ResetDevice</i>	Resets an SD card connected to the SD controller. See the ResetDevice() function description.

EFI_SD_MMC_PASS_THRU_PROTOCOL.PassThru()

Summary

Sends SD command to an SD card that is attached to the SD controller.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_SD_MMC_PASS_THRU_PASSTHRU) (
    IN EFI_SD_MMC_PASS_THRU_PROTOCOL      *This,
    IN UINT8                               Slot,
    IN OUT EFI_SD_MMC_PASS_THRU_COMMAND_PACKET *Packet,
    IN EFI_EVENT                            Event OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_SD_MMC_PASS_THRU_PROTOCOL instance.
<i>Slot</i>	The slot number of the SD card to send the command to.
<i>Packet</i>	A pointer to the SD command data structure. See “Related Definitions” below for a description of EFI_SD_MMC_PASS_THRU_COMMAND_PACKET .
<i>Event</i>	If non-blocking I/O is not supported then <i>Event</i> is ignored, and blocking I/O is performed. If <i>Event</i> is NULL , then blocking I/O is performed. If <i>Event</i> is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and <i>Event</i> will be signaled when the SD command completes.

Related Definitions

```
typedef struct {
    EFI_SD_MMC_COMMAND_BLOCK      *SdMmcCmdBlk;
    EFI_SD_MMC_STATUS_BLOCK      *SdMmcStatusBlk;
    UINT64                        Timeout;
    VOID                          *InDataBuffer;
    VOID                          *OutDataBuffer;
    UINT32                        InTransferLength;
    UINT32                        OutTransferLength;
    EFI_STATUS                     TransactionStatus;
} EFI_SD_MMC_PASS_THRU_COMMAND_PACKET;
```

<i>SdMmcCmdBlk</i>	A pointer to a command specific data buffer allocated and filled by the caller. See “Related Definitions” below for a description of EFI_SD_MMC_COMMAND_BLOCK .
<i>SdMmcStatusBlk</i>	A pointer to a command specific response data buffer allocated by the caller and filled by the PassThru function. See “Related Definitions” below for a description of EFI_SD_MMC_STATUS_BLOCK .

<i>Timeout</i>	The timeout, in 100 ns units, to use for the execution of this SDcommand. A <i>Timeout</i> value of 0 means that this function will wait indefinitely for the SDcommand to execute. If <i>Timeout</i> is greater than zero, then this function will return EFI_TIMEOUT if the time required to execute the SDcommand is greater than <i>Timeout</i> .
<i>InDataBuffer</i>	A pointer to a buffer for the data transferred from the SD card during processing of read and bidirectional commands. For all write and non-data commands this field is optional and may be NULL .
<i>OutDataBuffer</i>	A pointer to a buffer for the data to be transferred to the SD card during processing of write or bidirectional commands. For all read and non-data commands this field is optional and may be NULL .
<i>InTransferLength</i>	On input, the size, in bytes, of <i>InDataBuffer</i> . On output, the number of bytes transferred between the SD controller and the SD device. If <i>InTransferLength</i> is larger than the SD controller can handle, no data will be transferred, <i>InTransferLength</i> will be updated to contain the number of bytes that the SD controller is able to transfer, and EFI_BAD_BUFFER_SIZE will be returned.
<i>OutTransferLength</i>	On Input, the size, in bytes of <i>OutDataBuffer</i> . On Output, the Number of bytes transferred between SD Controller and the SD device. If <i>OutTransferLength</i> is larger than the SD controller can handle, no data will be transferred. <i>OutTransferLength</i> will be updated to contain the number of bytes that the SD controller is able to transfer, and EFI_BAD_BUFFER_SIZE will be returned.
<i>TransactionStatus</i>	Transaction status. When PathThru() function is used in a blocking mode, the status must be the same as the status returned by the PathThru() function. When PathThru() function is used in a non-blocking mode, the field is updated with the transaction status once transaction is completed.

} EFI_SD_MMC_RESPONSE_TYPE;

```

Description

The **PassThru()** function sends the SD command specified by *Packet* to the SD card specified by *Slot*.

If *Packet* is successfully sent to the SD card, then **EFI_SUCCESS** is returned. If a device error occurs while sending the *Packet*, then **EFI_DEVICE_ERROR** is returned. If *Slot* is not in a valid range for the SD controller, then **EFI_INVALID_PARAMETER** is returned. If *Packet* defines a data command but both *InDataBuffer* and *OutDataBuffer* are **NULL**, **EFI_INVALID_PARAMETER** is returned.

Status Codes Returned

EFI_SUCCESS	The SD Command Packet was sent by the host.
EFI_DEVICE_ERROR	A device error occurred while attempting to send the SD command Packet.
EFI_INVALID_PARAMETER	<i>Packet</i> , <i>Slot</i> , or the contents of the <i>Packet</i> is invalid.
EFI_INVALID_PARAMETER	<i>Packet</i> defines a data command but both <i>InDataBuffer</i> and <i>OutDataBuffer</i> are NULL .
EFI_NO_MEDIA	SD Device not present in the <i>Slot</i> .
EFI_UNSUPPORTED	The command described by the SD Command Packet is not supported by the host controller.
EFI_BAD_BUFFER_SIZE	The <i>InTransferLength</i> or <i>OutTransferLength</i> exceeds the limit supported by SD card (i.e. if the number of bytes exceed the Last LBA).
EFI_DEVICE_ERROR	The command was not sent due to a device error

EFI_SD_MMC_PASS_THRU_PROTOCOL.GetNextSlot()

Summary

Used to retrieve next slot numbers supported by the SD controller. The function returns information about all available slots (populated or not-populated).

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SD_MMC_PASS_THRU_GET_NEXT_SLOT) (
    IN EFI_SD_MMC_PASS_THRU_PROTOCOL *This,
    IN OUT UINT8                      *Slot
);
```

Parameters

<i>This</i>	A pointer to the EFI_SD_MMC_PASS_THRU_PROTOCOL instance.
<i>Slot</i>	On input, a pointer to a slot number on the SD controller. On output, a pointer to the next slot number on the SD controller. An input value of 0xFF retrieves the first slot number on the SD controller.

Description

The **GetNextSlot()** function retrieves the next slot number on an SD controller. If on input *Slot* is **0xFF**, then the slot number of the first slot on the SD controller is returned.

If *Slot* is a slot number that was returned on a previous call to **GetNextSlot()**, then the slot number of the next slot on the SD controller is returned.

If *Slot* is not **0xFF** and *Slot* was not returned on a previous call to **GetNextSlot()**, **EFI_INVALID_PARAMETER** is returned.

If *Slot* is the slot number of the last slot on the SD controller, then **EFI_NOT_FOUND** is returned.

Status Codes Returned

EFI_SUCCESS	The next slot number on the SD controller was returned in <i>Slot</i> .
EFI_NOT_FOUND	There are no more slots on this SD controller
EFI_INVALID_PARAMETER	<i>Slot</i> is not 0xFF and <i>Slot</i> was not returned on a previous call to GetNextSlot() .

EFI_SD_MMC_PASS_THRU_PROTOCOL.BuildDevicePath()

Summary

Used to allocate and build a device path node for an SD card on the SD controller.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_SD_MMC_PASS_THRU_BUILD_DEVICE_PATH) (
    IN EFI_SD_MMC_PASS_THRU_PROTOCOL *This,
    IN UINT8 Slot,
    IN OUT EFI_DEVICE_PATH_PROTOCOL **DevicePath
);
```

Parameters

<i>This</i>	A pointer to the EFI_SD_MMC_PASS_THRU_PROTOCOL instance.
<i>Slot</i>	Specifies the slot number of the SD card for which a device path node is to be allocated and built.
<i>DevicePath</i>	A pointer to a single device path node that describes the SD card specified by <i>Slot</i> . This function is responsible for allocating the buffer <i>DevicePath</i> with the boot service AllocatePool() . It is the caller's responsibility to free <i>DevicePath</i> when the caller is finished with <i>DevicePath</i> .

Description

The **BuildDevicePath()** function allocates and builds a single device node for the SD card specified by *Slot*. If the SD card specified by *Slot* is not present on the SD controller, then **EFI_NOT_FOUND** is returned. If *DevicePath* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If there are not enough resources to allocate the device path node, then **EFI_OUT_OF_RESOURCES** is returned.

Otherwise, *DevicePath* is allocated with the boot service **AllocatePool()**, the contents of *DevicePath* are initialized to describe the SD card specified by *Slot*, and **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The device path node that describes the SD card specified by Slot was allocated and returned in DevicePath.
EFI_NOT_FOUND	The SD card specified by Slot does not exist on the SD controller
EFI_INVALID_PARAMETER	DevicePath is NULL
EFI_OUT_OF_RESOURCES	There are not enough resources to allocate DevicePath

EFI_SD_MMC_PASS_THRU_PROTOCOL.GetSlotNumber()

Summary

This function retrieves an SD card slot number based on the input device path.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SD_MMC_PASS_THRU_GET_SLOT_NUMBER) (
    IN EFI_SD_MMC_PASS_THRU_PROTOCOL          *This,
    IN EFI_DEVICE_PATH_PROTOCOL              *DevicePath,
    OUT UINT8                                *Slot
);
```

Parameters

- This* A pointer to the **EFI_SD_MMC_PASS_THRU_PROTOCOL** instance.
- DevicePath* A pointer to the device path node that describes a SD card on the SD controller.
- Slot* On return, points to the slot number of an SD card on the SD controller.

Description

The **GetSlotNumber()** function retrieves slot number for the SD card specified by the *DevicePath* node. If *DevicePath* is **NULL**, **EFI_INVALID_PARAMETER** is returned. If *DevicePath* is not a device path node type that the SD Pass Thru driver supports, **EFI_UNSUPPORTED** is returned.

Status Codes Returned

EFI_SUCCESS	SD card slot number is returned in <i>Slot</i> .
EFI_INVALID_PARAMETER	<i>Slot</i> or <i>DevicePath</i> is NULL.
EFI_UNSUPPORTED	<i>DevicePath</i> is not a device path node type that the SD Pass Thru driver supports.

EFI_SD_MMC_PASS_THRU_PROTOCOL.ResetDevice()

Summary

Resets an SD card that is connected to the SD controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SD_MMC_PASS_THRU_RESET_DEVICE) (
    IN EFI_SD_MMC_PASS_THRU_PROTOCOL  *This,
    IN UINT8                          Slot
);
```

Parameters

This A pointer to the **EFI_SD_MMC_PASS_THRU_PROTOCOL** instance.

Slot Specifies the slot number of the SD card to be reset.

Description

The **ResetDevice()** function resets the SD card specified by *Slot*. If this SD controller does not support a device reset operation, **EFI_UNSUPPORTED** is returned. If *Slot* is not in a valid slot number for this SD controller, **EFI_INVALID_PARAMETER** is returned.

If the device reset operation is completed, **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The SD card specified by Slot was reset.
EFI_UNSUPPORTED	The SD controller does not support a device reset operation.
EFI_INVALID_PARAMETER	Slot number is invalid.
EFI_NO_MEDIA	SD Device not present in the <i>Slot</i> .
EFI_DEVICE_ERROR	The reset command failed due to a device error

12.17 RAM Disk Protocol

EFI_RAM_DISK_PROTOCOL

Summary

RAM disk aware application invokes this protocol to register/unregister a specified RAM disk.

GUID

```
#define EFI_RAM_DISK_PROTOCOL_GUID \
    { 0xab38a0df, 0x6873, 0x44a9, \
      { 0x87, 0xe6, 0xd4, 0xeb, 0x56, 0x14, 0x84, 0x49 } }
```

Protocol Interface Structure

```
typedef struct _EFI_RAM_DISK_PROTOCOL {
    EFI_RAM_DISK_REGISTER_RAMDISK    Register;
    EFI_RAM_DISK_UNREGISTER_RAMDISK  Unregister;
} EFI_RAM_DISK_PROTOCOL;
```

Members

<i>Register</i>	Register a RAM disk with specified buffer address, size and type.
<i>Unregister</i>	Unregister the RAM disk specified by a device path.

Description

This protocol defines a standard interface for UEFI applications, drivers and OS loaders to register/unregister a RAM disk.

The key points are:

- The consumer of this protocol is responsible for allocating/freeing memory used by RAM Disk if needed and deciding the initial content, as in most scenarios only the consumer knows which type and how much memory should be used.

EFI_RAM_DISK_PROTOCOL.Register()

Summary

This function is used to register a RAM disk with specified address, size and type.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_RAM_DISK_REGISTER_RAMDISK) (
    IN UINT64                RamDiskBase,
    IN UINT64                RamDiskSize,
    IN EFI_GUID              *RamDiskType,
    IN EFI_DEVICE_PATH       *ParentDevicePath OPTIONAL,
    OUT EFI_DEVICE_PATH_PROTOCOL **DevicePath
);
```

Parameters

<i>RamDiskBase</i>	The base address of registered RAM disk.
<i>RamDiskSize</i>	The size of registered RAM disk.
<i>RamDiskType</i>	The type of registered RAM disk. The GUID can be any of the values defined in Section 9.3.6.9 , or a vendor defined GUID.
<i>ParentDevicePath</i>	Pointer to the parent device path. If there is no parent device path then <i>ParentDevicePath</i> is NULL .
<i>DevicePath</i>	On return, points to a pointer to the device path of the RAM disk device. If <i>ParentDevicePath</i> is not NULL , the returned <i>DevicePath</i> is created by appending a RAM disk node to the parent device path. If <i>ParentDevicePath</i> is NULL , the returned <i>DevicePath</i> is a RAM disk device path without appending. This function is responsible for allocating the buffer <i>DevicePath</i> with the boot service AllocatePool () .

Description

The *Register* function is used to register a specified RAM Disk. The consumer of this API is responsible for allocating the space of the RAM disk and deciding the initial content of the RAM disk. The producer of this API is responsible for installing the RAM disk device path and block I/O related protocols on the RAM disk device handle.

RamDiskBase, *RamDiskSize* and *RamDiskType* are used to fill RAM disk device node. If *RamDiskSize* is 0, then **EFI_INVALID_PARAMETER** is returned. If *RamDiskType* is **NULL**, then **EFI_INVALID_PARAMETER** is returned.

DevicePath returns the device path of the registered RAM disk. If *DevicePath* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If there are not enough resources to allocate the device path node, then **EFI_OUT_OF_RESOURCES** is returned. Otherwise, *DevicePath* is allocated with the boot service **AllocatePool ()**. If *ParentDevicePath* is not **NULL** the *DevicePath* instance is created by appending a RAM disk device node to the

ParentDevicePath. If *ParentDevicePath* is **NULL** the *DevicePath* instance is a pure RAM disk device path. If the created *DevicePath* instance is already present in the handle database, then **EFI_ALREADY_STARTED** is returned.

Status Codes Returned

EFI_SUCCESS	The RAM disk is registered successfully.
EFI_INVALID_PARAMETER	<i>DevicePath</i> or <i>RamDiskType</i> is NULL .
EFI_INVALID_PARAMETER	<i>RamDiskSize</i> is 0.
EFI_ALREADY_STARTED	A Device Path Protocol instance to be created is already present in the handle database.
EFI_OUT_OF_RESOURCES	The RAM disk register operation fails due to resource limitation.

EFI_RAM_DISK_PROTOCOL.Unregister()

Summary

This function is used to unregister a RAM disk specified by *DevicePath*.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_RAM_DISK_UNREGISTER_RAMDISK) (
    IN EFI_DEVICE_PATH_PROTOCOL          *DevicePath
);
```

Parameters

DevicePath A pointer to the device path that describes a RAM Disk device.

Description

The *Unregister* function is used to unregister a specified RAM Disk. The producer of this protocol is responsible for uninstalling the RAM disk device path and block I/O related protocols and freeing the RAM disk device handle. It is the consumer of this protocol’s responsibility to free the memory used by this RAM disk.

Status Codes Returned

EFI_SUCCESS	The RAM disk is unregistered successfully.
EFI_INVALID_PARAMETER	<i>DevicePath</i> is NULL.
EFI_UNSUPPORTED	The device specified by <i>DevicePath</i> is not a valid ramdisk device path and not supported by the driver.
EFI_NOT_FOUND	The RAM disk pointed by <i>DevicePath</i> doesn’t exist.

Protocols — PCI Bus Support

13.1 PCI Root Bridge I/O Support

[Section 13.1](#) and [Section 13.2](#) describe the PCI Root Bridge I/O Protocol. This protocol provides an I/O abstraction for a PCI Root Bridge that is produced by a PCI Host Bus Controller. A PCI Host Bus Controller is a hardware component that allows access to a group of PCI devices that share a common pool of PCI I/O and PCI Memory resources. This protocol is used by a PCI Bus Driver to perform PCI Memory, PCI I/O, and PCI Configuration cycles on a PCI Bus. It also provides services to perform different types of bus mastering DMA on a PCI bus. PCI device drivers will not directly use this protocol. Instead, they will use the I/O abstraction produced by the PCI Bus Driver. Only drivers that require direct access to the entire PCI bus should use this protocol. In particular, this chapter defines functions for managing PCI buses, although other bus types may be supported in a similar fashion as extensions to this specification.

All the services described in this chapter that generate PCI transactions follow the ordering rules defined in the *PCI Specification*. If the processor is performing a combination of PCI transactions and system memory transactions, then there is no guarantee that the system memory transactions will be strongly ordered with respect to the PCI transactions. If strong ordering is required, then processor-specific mechanisms may be required to guarantee strong ordering. Some 64-bit systems may require the use of memory fences to guarantee ordering.

13.1.1 PCI Root Bridge I/O Overview

The interfaces provided in the [EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL](#) are for performing basic operations to memory, I/O, and PCI configuration space. The system provides abstracted access to basic system resources to allow a driver to have a programmatic method to access these basic system resources.

The [EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL](#) allows for future innovation of the platform. It abstracts device-specific code from the system memory map. This allows system designers to make changes to the system memory map without impacting platform independent code that is consuming basic system resources.

A platform can be viewed as a set of processors and a set of core chipset components that may produce one or more host buses. [Figure 31](#) shows a platform with n processors (*CPUs* in the figure), and a set of core chipset components that produce m host bridges.

Figure 31. Host Bus Controllers

Simple systems with one PCI Host Bus Controller will contain a single instance of the [EFI PCI ROOT BRIDGE IO PROTOCOL](#). More complex system may contain multiple instances of this protocol. It is important to note that there is no relationship between the number of chipset components in a platform and the number of [EFI PCI ROOT BRIDGE IO PROTOCOL](#) instances. This protocol abstracts access to a PCI Root Bridge from a software point of view, and it is attached to a device handle that represents a PCI Root Bridge. A PCI Root Bridge is a chipset component(s) that produces a physical PCI Bus. It is also the parent to a set of PCI devices that share common PCI I/O, PCI Memory, and PCI Prefetchable Memory regions. A PCI Host Bus Controller is composed of one or more PCI Root Bridges.

A PCI Host Bridge and PCI Root Bridge are different than a PCI Segment. A PCI Segment is a collection of up to 256 PCI busses that share the same PCI Configuration Space. Depending on the chipset, a single [EFI PCI ROOT BRIDGE IO PROTOCOL](#) may abstract a portion of a PCI Segment, or an entire PCI Segment. A PCI Host Bridge may produce one or more PCI Root Bridges. When a PCI Host Bridge produces multiple PCI Root Bridges, it is possible to have more than one PCI Segment.

PCI Root Bridge I/O Protocol instances are either produced by the system firmware or by a UEFI driver. When a PCI Root Bridge I/O Protocol is produced, it is placed on a device handle along with an EFI Device Path Protocol instance. [Figure 32](#) shows a sample device handle for a PCI Root Bridge Controller that includes an instance of the [EFI DEVICE PATH PROTOCOL](#) and the [EFI PCI ROOT BRIDGE IO PROTOCOL](#). [Section 13.2](#) describes the PCI Root Bridge I/O Protocol in detail, and [Section 13.2.1](#) describes how to build device paths for PCI Root Bridges. The [EFI PCI ROOT BRIDGE IO PROTOCOL](#) does not abstract access to the chipset-specific registers that are used to manage a PCI Root Bridge. This functionality is hidden within the system firmware or the driver that produces the handles that represent the PCI Root Bridges.

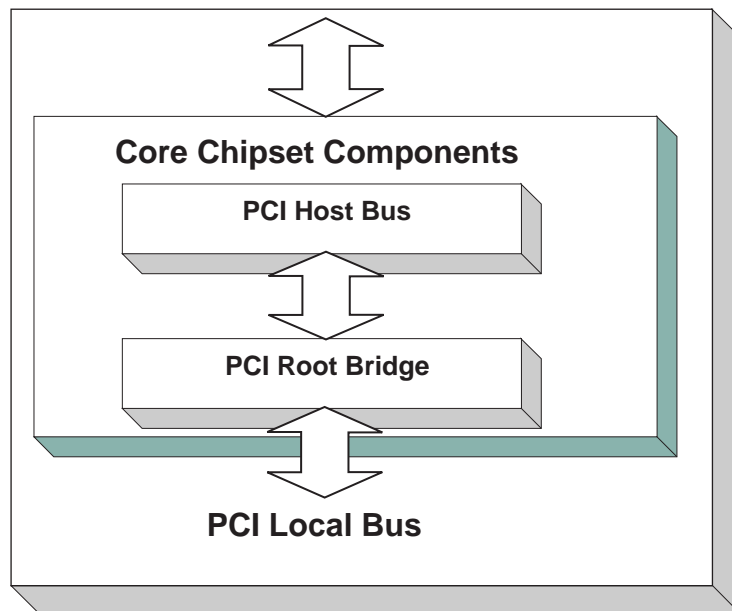

OM13151

Figure 32. Device Handle for a PCI Root Bridge Controller

13.1.1.1 Sample PCI Architectures

The PCI Root Bridge I/O Protocol is designed to provide a software abstraction for a wide variety of PCI architectures including the ones described in this section. This section is not intended to be an exhaustive list of the PCI architectures that the PCI Root Bridge I/O Protocol can support. Instead, it is intended to show the flexibility of this protocol to adapt to current and future platform designs.

[Figure 33](#) shows an example of a PCI Host Bus with one PCI Root Bridge. This PCI Root Bridge produces one PCI Local Bus that can contain PCI Devices on the motherboard and/or PCI slots. This would be typical of a desktop system. A higher end desktop system might contain a second PCI Root Bridge for AGP devices. The firmware for this platform would produce one instance of the PCI Root Bridge I/O Protocol.

OM13161

Figure 33. Desktop System with One PCI Root Bridge

[Figure 34](#) shows an example of a larger server with one PCI Host Bus and four PCI Root Bridges. The PCI devices attached to the PCI Root Bridges are all part of the same coherency domain. This means they share a common PCI I/O Space, a common PCI Memory Space, and a common PCI Prefetchable Memory Space. Each PCI Root Bridge produces one PCI Local Bus that can contain PCI Devices on the motherboard or PCI slots. The firmware for this platform would produce four instances of the PCI Root Bridge I/O Protocol.

Figure 34. Server System with Four PCI Root Bridges

[Figure 35](#) shows an example of a server with one PCI Host Bus and two PCI Root Bridges. Each of these PCI Root Bridges is a different PCI Segment which allows the system to have up to 512 PCI Buses. A single PCI Segment is limited to 256 PCI Buses. These two segments do not share the same PCI Configuration Space, but they do share the same PCI I/O, PCI Memory, and PCI Prefetchable Memory Space. This is why it can be described by a single PCI Host Bus. The firmware for this platform would produce two instances of the PCI Root Bridge I/O Protocol.

Figure 35. Server System with Two PCI Segments

[Figure 36](#) shows a server system with two PCI Host Buses and one PCI Root Bridge per PCI Host Bus. This system supports up to 512 PCI Buses, but the PCI I/O, PCI Memory Space, and PCI Prefetchable Memory Space are not shared between the two PCI Root Bridges. The firmware for this platform would produce two instances of the PCI Root Bridge I/O Protocol.

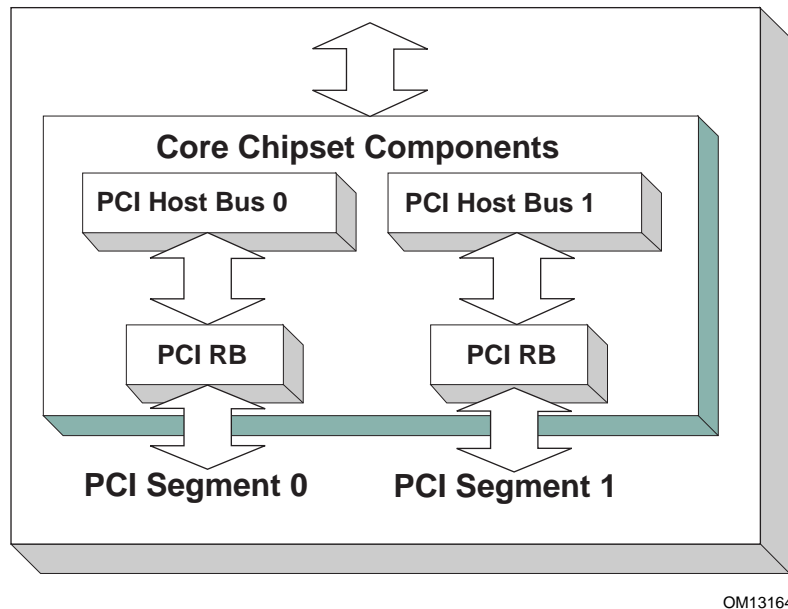

Figure 36. Server System with Two PCI Host Buses

13.2 PCI Root Bridge I/O Protocol

This section provides detailed information on the PCI Root Bridge I/O Protocol and its functions.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL

Summary

Provides the basic Memory, I/O, PCI configuration, and DMA interfaces that are used to abstract accesses to PCI controllers behind a PCI Root Bridge Controller.

GUID

```
#define EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_GUID \
  {0x2F707EBB, 0x4A1A, 0x11d4, \
   {0x9A, 0x38, 0x00, 0x90, 0x27, 0x3F, 0xC1, 0x4D}}
```

Protocol Interface Structure

```
typedef struct _EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL {
  EFI_HANDLE ParentHandle;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_POLL_IO_MEM PollMem;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_POLL_IO_MEM PollIo;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_ACCESS Mem;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_ACCESS Io;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_ACCESS Pci;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_COPY_MEM CopyMem;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_MAP Map;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_UNMAP Unmap;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_ALLOCATE_BUFFER AllocateBuffer;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_FREE_BUFFER FreeBuffer;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_FLUSH Flush;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_GET_ATTRIBUTES GetAttributes;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_SET_ATTRIBUTES SetAttributes;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_CONFIGURATION Configuration;
  UINT32 SegmentNumber;
} EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL;
```

Parameters

<i>ParentHandle</i>	The EFI_HANDLE of the PCI Host Bridge of which this PCI Root Bridge is a member.
<i>PollMem</i>	Polls an address in memory mapped I/O space until an exit condition is met, or a timeout occurs. See the PollMem() function description.
<i>PollIo</i>	Polls an address in I/O space until an exit condition is met, or a timeout occurs. See the PollIo() function description.

<i>Mem.Read</i>	Allows reads from memory mapped I/O space. See the Mem.Read() function description.
<i>Mem.Write</i>	Allows writes to memory mapped I/O space. See the Mem.Write() function description.
<i>Io.Read</i>	Allows reads from I/O space. See the Io.Read() function description.
<i>Io.Write</i>	Allows writes to I/O space. See the Io.Write() function description.
<i>Pci.Read</i>	Allows reads from PCI configuration space. See the Pci.Read() function description.
<i>Pci.Write</i>	Allows writes to PCI configuration space. See the Pci.Write() function description.
<i>CopyMem</i>	Allows one region of PCI root bridge memory space to be copied to another region of PCI root bridge memory space. See the CopyMem() function description.
<i>Map</i>	Provides the PCI controller–specific addresses needed to access system memory for DMA. See the Map() function description.
<i>Unmap</i>	Releases any resources allocated by Map() . See the Unmap() function description.
<i>AllocateBuffer</i>	Allocates pages that are suitable for a common buffer mapping. See the AllocateBuffer() function description.
<i>FreeBuffer</i>	Free pages that were allocated with AllocateBuffer() . See the FreeBuffer() function description.
<i>Flush</i>	Flushes all PCI posted write transactions to system memory. See the Flush() function description.
<i>GetAttributes</i>	Gets the attributes that a PCI root bridge supports setting with SetAttributes() , and the attributes that a PCI root bridge is currently using. See the GetAttributes() function description.
<i>SetAttributes</i>	Sets attributes for a resource range on a PCI root bridge. See the SetAttributes() function description.
<i>Configuration</i>	Gets the current resource settings for this PCI root bridge. See the Configuration() function description.
<i>SegmentNumber</i>	The segment number that this PCI root bridge resides.

EFI_PCI_ATTRIBUTE_ISA_IO_16

If this bit is set, then the PCI I/O cycles between 0x100 and 0x3FF are forwarded onto a PCI root bridge using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for legacy ISA devices onto a PCI root bridge. This bit may not be combined with **EFI_PCI_ATTRIBUTE_ISA_IO**.

EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO_16

If this bit is set, then the PCI I/O write cycles for 0x3C6, 0x3C8, and 0x3C9 are forwarded onto a PCI root bridge using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O write cycles to the VGA palette registers onto a PCI root bridge. This bit may not be combined with **EFI_PCI_ATTRIBUTE_VGA_IO** or **EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO**.

EFI_PCI_ATTRIBUTE_VGA_IO_16

If this bit is set, then the PCI I/O cycles in the ranges 0x3B0–0x3BB and 0x3C0–0x3DF are forwarded onto a PCI root bridge using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a VGA controller onto a PCI root bridge. This bit may not be combined with **EFI_PCI_ATTRIBUTE_VGA_IO** or **EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO**. Because **EFI_PCI_ATTRIBUTE_VGA_IO_16** also includes the I/O range described by **EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO_16**, the **EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO_16** bit is ignored if **EFI_PCI_ATTRIBUTE_VGA_IO_16** is set.

EFI_PCI_ATTRIBUTE_ISA_MOTHERBOARD_IO

If this bit is set, then the PCI I/O cycles between 0x00000000 and

0x000000FF are forwarded onto a PCI root bridge. This bit is used to forward I/O cycles for ISA motherboard devices onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_ISA_IO

If this bit is set, then the PCI I/O cycles between 0x100 and 0x3FF are forwarded onto a PCI root bridge using a 10-bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and address bits 16..31 must be zero. This bit is used to forward I/O cycles for legacy ISA devices onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO

If this bit is set, then the PCI I/O write cycles for 0x3C6, 0x3C8, and 0x3C9 are forwarded onto a PCI root bridge using a 10 bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and address bits 16..31 must be zero. This bit is used to forward I/O write cycles to the VGA palette registers onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_VGA_MEMORY

If this bit is set, then the PCI memory cycles between 0xA0000 and 0xBFFFF are forwarded onto a PCI root bridge. This bit is used to forward memory cycles for a VGA frame buffer onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_VGA_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x3B0-0x3BB and 0x3C0-0x3DF are forwarded onto a PCI root bridge using a 10-bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and the address bits 16..31 must be zero. This bit is used to forward I/O cycles for a VGA controller onto a PCI root bridge. Since

EFI_PCI_ATTRIBUTE_ENABLE_VGA_IO also includes the I/O range described by

EFI_PCI_ATTRIBUTE_ENABLE_VGA_PALETTE_IO, the **EFI_PCI_ATTRIBUTE_ENABLE_VGA_PALETTE_IO** bit is ignored if **EFI_PCI_ATTRIBUTE_ENABLE_VGA_IO** is set.

EFI_PCI_ATTRIBUTE_IDE_PRIMARY_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x1F0-0x1F7 and 0x3F6-0x3F7 are forwarded onto a PCI root bridge using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a Primary IDE controller onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_IDE_SECONDARY_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x170-0x177 and 0x376-0x377 are forwarded onto a PCI root bridge using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a Secondary IDE controller onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_MEMORY_WRITE_COMBINE

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is

accessed in a write combining mode. By default, PCI memory ranges are not accessed in a write combining mode.

EFI_PCI_ATTRIBUTE_MEMORY_CACHED

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is accessed in a cached mode. By default, PCI memory ranges are accessed noncached.

EFI_PCI_ATTRIBUTE_MEMORY_DISABLE

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is disabled, and can no longer be accessed. By default, all PCI memory ranges are enabled.

EFI_PCI_ATTRIBUTE_DUAL_ADDRESS_CYCLE

This bit may only be used in the *Attributes* parameter to [AllocateBuffer\(\)](#). If this bit is set, then the PCI controller that is requesting a buffer through **AllocateBuffer()** is capable of producing PCI Dual Address Cycles, so it is able to access a 64-bit address space. If this bit is not set, then the PCI controller that is requesting a buffer through **AllocateBuffer()** is not capable of producing PCI Dual Address Cycles, so it is only able to access a 32-bit address space.

```

//*****
// EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_OPERATION
//*****
typedef enum {
    EfiPciOperationBusMasterRead,
    EfiPciOperationBusMasterWrite,
    EfiPciOperationBusMasterCommonBuffer,
    EfiPciOperationBusMasterRead64,

    EfiPciOperationMaximum
} EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_OPERATION;

```

EfiPciOperationBusMasterRead

A read operation from system memory by a bus master that is not capable of producing PCI dual address cycles.

EfiPciOperationBusMasterWrite

A write operation to system memory by a bus master that is not capable of producing PCI dual address cycles.

EfiPciOperationBusMasterCommonBuffer

Provides both read and write access to system memory by both the processor and a bus master that is not capable of producing PCI dual address cycles. The buffer is coherent from both the processor's and the bus master's point of view.

EfiPciOperationBusMasterRead64

A read operation from system memory by a bus master that is capable of producing PCI dual address cycles.

EfiPciOperationBusMasterWrite64

A write operation to system memory by a bus master that is capable of producing PCI dual address cycles.

EfiPciOperationBusMasterCommonBuffer64

Provides both read and write access to system memory by both the processor and a bus master that is capable of producing PCI dual address cycles. The buffer is coherent from both the processor's and the bus master's point of view.

Description

The **EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL** provides the basic Memory, I/O, PCI configuration, and DMA interfaces that are used to abstract accesses to PCI controllers. There is one **EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL** instance for each PCI root bridge in a system. Embedded systems, desktops, and workstations will typically only have one PCI root bridge. High-end servers may have multiple PCI root bridges. A device driver that wishes to manage a PCI bus in a system will have to retrieve the **EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL** instance that is associated with the PCI bus to be managed. A device handle for a PCI Root Bridge will minimally contain an [EFI_DEVICE_PATH_PROTOCOL](#) instance and an **EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL** instance. The PCI bus driver can look at the [EFI_DEVICE_PATH_PROTOCOL](#) instances to determine which **EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL** instance to use.

Bus mastering PCI controllers can use the DMA services for DMA operations. There are three basic types of bus mastering DMA that is supported by this protocol. These are DMA reads by a bus master, DMA writes by a bus master, and common buffer DMA. The DMA read and write operations may need to be broken into smaller chunks. The caller of [Map\(\)](#) must pay attention to the number of bytes that were mapped, and if required, loop until the entire buffer has been transferred. The following is a list of the different bus mastering DMA operations that are supported, and the sequence of **EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL** APIs that are used for each DMA operation type. See “Related Definitions” above for the definition of the different DMA operation types.

DMA Bus Master Read Operation

- Call [Map\(\)](#) for **EfiPciOperationBusMasterRead** or **EfiPciOperationBusMasterRead64**.
- Program the DMA Bus Master with the *DeviceAddress* returned by **Map()**.
- Start the DMA Bus Master.
- Wait for DMA Bus Master to complete the read operation.
- Call [Unmap\(\)](#).

DMA Bus Master Write Operation

- Call **Map()** for **EfiPciOperationBusMasterWrite** or **EfiPciOperationBusMasterRead64**.

- Program the DMA Bus Master with the *DeviceAddress* returned by [Map \(\)](#).
- Start the DMA Bus Master.
- Wait for DMA Bus Master to complete the write operation.
- Perform a PCI controller specific read transaction to flush all PCI write buffers (See *PCI Specification* Section 3.2.5.2) .
- Call [Flush \(\)](#) .
- Call [Unmap \(\)](#) .

DMA Bus Master Common Buffer Operation

- Call [AllocateBuffer \(\)](#) to allocate a common buffer.
- Call [Map \(\)](#) for **EfiPciOperationBusMasterCommonBuffer** or **EfiPciOperationBusMasterCommonBuffer64**.
- Program the DMA Bus Master with the *DeviceAddress* returned by [Map \(\)](#) .
- The common buffer can now be accessed equally by the processor and the DMA bus master.
- Call [Unmap \(\)](#) .
- Call [FreeBuffer \(\)](#) .

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.PollMem()

Summary

Reads from the memory space of a PCI Root Bridge. Returns when either the polling exit criteria is satisfied or after a defined duration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_POLL_IO_MEM) (
    IN  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL      *This,
    IN  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH Width,
    IN  UINT64                               Address,
    IN  UINT64                               Mask,
    IN  UINT64                               Value,
    IN  UINT64                               Delay,
    OUT UINT64                               *Result
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI ROOT BRIDGE IO PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Width</i>	Signifies the width of the memory operations. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH is defined in Section 13.2 .
<i>Address</i>	The base address of the memory operations. The caller is responsible for aligning <i>Address</i> if required.
<i>Mask</i>	Mask used for the polling criteria. Bytes above <i>Width</i> in <i>Mask</i> are ignored. The bits in the bytes below <i>Width</i> which are zero in <i>Mask</i> are ignored when polling the memory address.
<i>Value</i>	The comparison value used for the polling exit criteria.
<i>Delay</i>	The number of 100 ns units to poll. Note that timer available may be of poorer granularity.
<i>Result</i>	Pointer to the last value read from the memory location.

Description

This function provides a standard way to poll a PCI memory location. A PCI memory read operation is performed at the PCI memory address specified by *Address* for the width specified by *Width*. The result of this PCI memory read operation is stored in *Result*. This PCI memory read operation is repeated until either a timeout of *Delay* 100 ns units has expired, or (*Result* & *Mask*) is equal to *Value*.

This function will always perform at least one PCI memory read access no matter how small *Delay* may be. If *Delay* is zero, then *Result* will be returned with a status of **EFI_SUCCESS** even if *Result* does not match the exit criteria. If *Delay* expires, then **EFI_TIMEOUT** is returned.

If *Width* is not **EfiPciWidthUint8**, **EfiPciWidthUint16**, **EfiPciWidthUint32**, or **EfiPciWidthUint64**, then **EFI_INVALID_PARAMETER** is returned.

The memory operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and memory width restrictions that a PCI Root Bridge on a platform might require. For example on some platforms, width requests of **EfiPciWidthUint64** are not supported.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns. However, if the memory mapped I/O region being accessed by this function has the **EFI_PCI_ATTRIBUTE_MEMORY_CACHED** attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The last data returned from the access matched the poll exit criteria.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid.
EFI_INVALID_PARAMETER	<i>Result</i> is NULL .
EFI_TIMEOUT	<i>Delay</i> expired before a match occurred.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.PollIo()

Summary

Reads from the I/O space of a PCI Root Bridge. Returns when either the polling exit criteria is satisfied or after a defined duration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_POLL_IO_MEM) (
    IN  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL      *This,
    IN  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH Width,
    IN  UINT64                               Address,
    IN  UINT64                               Mask,
    IN  UINT64                               Value,
    IN  UINT64                               Delay,
    OUT UINT64                               *Result
);
```

Parameters

<i>This</i>	A pointer to the EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Width</i>	Signifies the width of the I/O operations. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH is defined in Section 13.2 .
<i>Address</i>	The base address of the I/O operations. The caller is responsible for aligning <i>Address</i> if required.
<i>Mask</i>	Mask used for the polling criteria. Bytes above <i>Width</i> in <i>Mask</i> are ignored. The bits in the bytes below <i>Width</i> which are zero in <i>Mask</i> are ignored when polling the I/O address.
<i>Value</i>	The comparison value used for the polling exit criteria.
<i>Delay</i>	The number of 100 ns units to poll. Note that timer available may be of poorer granularity.
<i>Result</i>	Pointer to the last value read from the memory location.

Description

This function provides a standard way to poll a PCI I/O location. A PCI I/O read operation is performed at the PCI I/O address specified by *Address* for the width specified by *Width*. The result of this PCI I/O read operation is stored in *Result*. This PCI I/O read operation is repeated until either a timeout of *Delay* 100 ns units has expired, or (*Result & Mask*) is equal to *Value*.

This function will always perform at least one I/O access no matter how small *Delay* may be. If *Delay* is zero, then *Result* will be returned with a status of **EFI_SUCCESS** even if *Result* does not match the exit criteria. If *Delay* expires, then **EFI_TIMEOUT** is returned.

If *Width* is not **EfiPciWidthUint8**, **EfiPciWidthUint16**, **EfiPciWidthUint32**, or **EfiPciWidthUint64**, then **EFI_INVALID_PARAMETER** is returned.

The I/O operations are carried out exactly as requested. The caller is responsible satisfying any alignment and I/O width restrictions that the PCI Root Bridge on a platform might require. For example on some platforms, width requests of **EfiPciWidthUint64** do not work.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns.

Status Codes Returned

EFI_SUCCESS	The last data returned from the access matched the poll exit criteria.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid.
EFI_INVALID_PARAMETER	<i>Result</i> is NULL .
EFI_TIMEOUT	<i>Delay</i> expired before a match occurred.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Mem.Read() EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Mem.Write()

Summary

Enables a PCI driver to access PCI controller registers in the PCI root bridge memory space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_IO_MEM) (
    IN      EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL      *This,
    IN      EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH Width,
    IN      UINT64                               Address,
    IN      UINTN                                Count,
    IN OUT VOID                               *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI ROOT BRIDGE IO PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Width</i>	Signifies the width of the memory operation. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH is defined in Section 13.2 .
<i>Address</i>	The base address of the memory operation. The caller is responsible for aligning the <i>Address</i> if required.
<i>Count</i>	The number of memory operations to perform. Bytes moved is <i>Width</i> size * <i>Count</i> , starting at <i>Address</i> .
<i>Buffer</i>	For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The **Mem.Read()**, and **Mem.Write()** functions enable a driver to access PCI controller registers in the PCI root bridge memory space.

The memory operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and memory width restrictions that a PCI Root Bridge on a platform might require. For example on some platforms, width requests of **EfiPciWidthUint64** do not work.

If *Width* is **EfiPciWidthUint8**, **EfiPciWidthUint16**, **EfiPciWidthUint32**, or **EfiPciWidthUint64**, then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is **EfiPciWidthFifoUint8**, **EfiPciWidthFifoUint16**, **EfiPciWidthFifoUint32**, or **EfiPciWidthFifoUint64**, then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is **EfiPciWidthFillUint8**, **EfiPciWidthFillUint16**, **EfiPciWidthFillUint32**, or **EfiPciWidthFillUint64**, then only *Address* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI read transactions generated by this function are guaranteed to be completed before this function returns. All the PCI write transactions generated by this function will follow the write ordering and completion rules defined in the *PCI Specification*. However, if the memory-mapped I/O region being accessed by this function has the **EFI_PCI_ATTRIBUTE_MEMORY_CACHED** attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI root bridge.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid for this PCI root bridge.
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL .
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL Io.Read() EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL Io.Write()

Summary

Enables a PCI driver to access PCI controller registers in the PCI root bridge I/O space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_IO_MEM) (
    IN      EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL      *This,
    IN      EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH Width,
    IN      UINT64                               Address,
    IN      UINTN                                Count,
    IN OUT VOID                               *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI ROOT BRIDGE IO PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Width</i>	Signifies the width of the memory operations. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH is defined in Section 13.2 .
<i>Address</i>	The base address of the I/O operation. The caller is responsible for aligning the <i>Address</i> if required.
<i>Count</i>	The number of I/O operations to perform. Bytes moved is <i>Width</i> size * <i>Count</i> , starting at <i>Address</i> .
<i>Buffer</i>	For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The **Io.Read()**, and **Io.Write()** functions enable a driver to access PCI controller registers in the PCI root bridge I/O space.

The I/O operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and I/O width restrictions that a PCI root bridge on a platform might require. For example on some platforms, width requests of **EfiPciWidthUint64** do not work.

If *Width* is **EfiPciWidthUint8**, **EfiPciWidthUint16**, **EfiPciWidthUint32**, or **EfiPciWidthUint64**, then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is **EfiPciWidthFifoUint8**, **EfiPciWidthFifoUint16**, **EfiPciWidthFifoUint32**, or **EfiPciWidthFifoUint64**, then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is **EfiPciWidthFillUint8**, **EfiPciWidthFillUint16**, **EfiPciWidthFillUint32**, or **EfiPciWidthFillUint64**, then only *Address* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI root bridge.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid for this PCI root bridge.
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL .
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Pci.Read() EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Pci.Write()

Summary

Enables a PCI driver to access PCI controller registers in a PCI root bridge's configuration space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_IO_MEM) (
    IN      EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL      *This,
    IN      EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH Width,
    IN      UINT64                               Address,
    IN      UINTN                                Count,
    IN OUT VOID                               *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI ROOT BRIDGE IO PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Width</i>	Signifies the width of the memory operations. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH is defined in Section 13.2 .
<i>Address</i>	The address within the PCI configuration space for the PCI controller. See Table 111 for the format of <i>Address</i> .
<i>Count</i>	The number of PCI configuration operations to perform. Bytes moved is <i>Width</i> size * <i>Count</i> , starting at <i>Address</i> .
<i>Buffer</i>	For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The **Pci.Read()** and **Pci.Write()** functions enable a driver to access PCI configuration registers for a PCI controller.

The PCI Configuration operations are carried out exactly as requested. The caller is responsible for any alignment and PCI configuration width issues that a PCI Root Bridge on a platform might require. For example on some platforms, width requests of **EfiPciWidthUint64** do not work.

If *Width* is **EfiPciWidthUint8**, **EfiPciWidthUint16**, **EfiPciWidthUint32**, or **EfiPciWidthUint64**, then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is **EfiPciWidthFifoUint8**, **EfiPciWidthFifoUint16**, **EfiPciWidthFifoUint32**, or **EfiPciWidthFifoUint64**, then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is **EfiPciWidthFillUint8**, **EfiPciWidthFillUint16**, **EfiPciWidthFillUint32**, or **EfiPciWidthFillUint64**, then only *Address* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns.

Table 111. PCI Configuration Address

Mnemonic	Byte Offset	Byte Length	Description
Register	0	1	The register number on the PCI Function.
Function	1	1	The PCI Function number on the PCI Device.
Device	2	1	The PCI Device number on the PCI Bus.
Bus	3	1	The PCI Bus number.
ExtendedRegister	4	4	The register number on the PCI Function. If this field is zero, then the Register field is used for the register number. If this field is nonzero, then the Register field is ignored, and the ExtendedRegister field is used for the register number.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI root bridge.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid for this PCI root bridge.
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL .
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.CopyMem()

Summary

Enables a PCI driver to copy one region of PCI root bridge memory space to another region of PCI root bridge memory space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_COPY_MEM) (
    IN     EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL      *This,
    IN     EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH Width,
    IN     UINT64                               DestAddress,
    IN     UINT64                               SrcAddress,
    IN     UINTN                                Count
);
```

Parameters

<i>This</i>	A pointer to the EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL instance. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Width</i>	Signifies the width of the memory operations. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH is defined in Section 13.2 .
<i>DestAddress</i>	The destination address of the memory operation. The caller is responsible for aligning the <i>DestAddress</i> if required.
<i>SrcAddress</i>	The source address of the memory operation. The caller is responsible for aligning the <i>SrcAddress</i> if required.
<i>Count</i>	The number of memory operations to perform. Bytes moved is <i>Width</i> size * <i>Count</i> , starting at <i>DestAddress</i> and <i>SrcAddress</i> .

Description

The **CopyMem()** function enables a PCI driver to copy one region of PCI root bridge memory space to another region of PCI root bridge memory space. This is especially useful for video scroll operation on a memory mapped video buffer.

The memory operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and memory width restrictions that a PCI root bridge on a platform might require. For example on some platforms, width requests of **EfiPciWidthUint64** do not work.

If *Width* is **EfiPciIoWidthUint8**, **EfiPciIoWidthUint16**, **EfiPciIoWidthUint32**, or **EfiPciIoWidthUint64**, then *Count* read/write transactions are performed to move the contents of the *SrcAddress* buffer to the *DestAddress* buffer. The implementation must be reentrant, and it must handle overlapping *SrcAddress* and *DestAddress* buffers. This means that the implementation of **CopyMem()** must choose the correct direction of the copy operation based on the type of overlap that exists between the *SrcAddress* and *DestAddress* buffers. If

either the *SrcAddress* buffer or the *DestAddress* buffer crosses the top of the processor’s address space, then the result of the copy operation is unpredictable.

The contents of the *DestAddress* buffer on exit from this service must match the contents of the *SrcAddress* buffer on entry to this service. Due to potential overlaps, the contents of the *SrcAddress* buffer may be modified by this service. The following rules can be used to guarantee the correct behavior:

- If $DestAddress > SrcAddress$ and $DestAddress < (SrcAddress + Width \text{ size} * Count)$, then the data should be copied from the *SrcAddress* buffer to the *DestAddress* buffer starting from the end of buffers and working toward the beginning of the buffers.
- Otherwise, the data should be copied from the *SrcAddress* buffer to the *DestAddress* buffer starting from the beginning of the buffers and working toward the end of the buffers.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns. All the PCI write transactions generated by this function will follow the write ordering and completion rules defined in the *PCI Specification*. However, if the memory-mapped I/O region being accessed by this function has the **EFI_PCI_ATTRIBUTE_MEMORY_CACHED** attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The data was copied from one memory region to another memory region.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid for this PCI root bridge.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Map()

Summary

Provides the PCI controller-specific addresses required to access system memory from a DMA bus master.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_MAP) (
    IN      EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL      *This,
    IN      EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_OPERATION Operation,
    IN      VOID                                *HostAddress,
    IN OUT  UINTN                               *NumberOfBytes,
    OUT     EFI_PHYSICAL_ADDRESS                *DeviceAddress,
    OUT     VOID                                **Mapping
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI ROOT BRIDGE IO PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Operation</i>	Indicates if the bus master is going to read or write to system memory. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_OPERATION is defined in Section 13.2 .
<i>HostAddress</i>	The system memory address to map to the PCI controller.
<i>NumberOfBytes</i>	On input the number of bytes to map. On output the number of bytes that were mapped.
<i>DeviceAddress</i>	The resulting map address for the bus master PCI controller to use to access the system memory's <i>HostAddress</i> . Type EFI_PHYSICAL_ADDRESS is defined in Section 6.2 , EFI_BOOT_SERVICES.AllocatePages() . This address cannot be used by the processor to access the contents of the buffer specified by <i>HostAddress</i> .
<i>Mapping</i>	The value to pass to Unmap() when the bus master DMA operation is complete.

Description

The **Map()** function provides the PCI controller specific addresses needed to access system memory. This function is used to map system memory for PCI bus master DMA accesses.

All PCI bus master accesses must be performed through their mapped addresses and such mappings must be freed with [Unmap\(\)](#) when complete. If the bus master access is a single read or single write data transfer, then [EfiPciOperationBusMasterRead](#), [EfiPciOperationBusMasterRead64](#), [EfiPciOperationBusMasterWrite](#), or

EfiPciOperationBusMasterWrite64 is used and the range is unmapped to complete the operation. If performing an **EfiPciOperationBusMasterRead** or **EfiPciOperationBusMasterRead64** operation, all the data must be present in system memory before **Map ()** is performed. Similarly, if performing an **EfiPciOperation-BusMasterWrite** or **EfiPciOperationBusMasterWrite64** the data cannot be properly accessed in system memory until **Unmap ()** is performed.

Bus master operations that require both read and write access or require multiple host device interactions within the same mapped region must use **EfiPciOperation-BusMasterCommonBuffer** or **EfiPciOperationBusMasterCommonBuffer64**. However, only memory allocated via the [AllocateBuffer \(\)](#) interface can be mapped for this type of operation.

In all mapping requests the resulting *NumberOfBytes* actually mapped may be less than the requested amount. In this case, the DMA operation will have to be broken up into smaller chunks. The **Map ()** function will map as much of the DMA operation as it can at one time. The caller may have to loop on **Map ()** and **Unmap ()** in order to complete a large DMA transfer.

Status Codes Returned

EFI_SUCCESS	The range was mapped for the returned <i>NumberOfBytes</i> .
EFI_INVALID_PARAMETER	<i>Operation</i> is invalid.
EFI_INVALID_PARAMETER	<i>HostAddress</i> is NULL .
EFI_INVALID_PARAMETER	<i>NumberOfBytes</i> is NULL .
EFI_INVALID_PARAMETER	<i>DeviceAddress</i> is NULL .
EFI_INVALID_PARAMETER	<i>Mapping</i> is NULL .
EFI_UNSUPPORTED	The <i>HostAddress</i> cannot be mapped as a common buffer.
EFI_DEVICE_ERROR	The system hardware could not map the requested address.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Unmap()

Summary

Completes the [Map \(\)](#) operation and releases any corresponding resources.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_UNMAP) (
    IN  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL  *This,
    IN  VOID                               *Mapping
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI ROOT BRIDGE IO PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Mapping</i>	The mapping value returned from Map () .

Description

The [Unmap \(\)](#) function completes the [Map \(\)](#) operation and releases any corresponding resources. If the operation was an [EfiPciOperationBusMasterWrite](#) or [EfiPciOperationBusMasterWrite64](#), the data is committed to the target system memory. Any resources used for the mapping are freed.

Status Codes Returned

EFI_SUCCESS	The range was unmapped.
EFI_INVALID_PARAMETER	<i>Mapping</i> is not a value that was returned by Map () .
EFI_DEVICE_ERROR	The data was not committed to the target system memory.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.AllocateBuffer()

Summary

Allocates pages that are suitable for an **EfiPciOperationBusMasterCommonBuffer** or **EfiPciOperationBusMasterCommonBuffer64** mapping.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_ALLOCATE_BUFFER) (
    IN      EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL  *This,
    IN      EFI_ALLOCATE_TYPE                Type,
    IN      EFI_MEMORY_TYPE                  MemoryType,
    IN      UINTN                             Pages,
    OUT     VOID                             **HostAddress,
    IN      UINT64                            Attributes
);
```

Parameters

<i>This</i>	A pointer to the EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2.1 .
<i>Type</i>	This parameter is not used and must be ignored.
<i>MemoryType</i>	The type of memory to allocate, EfiBootServicesData or EfiRuntimeServicesData . Type EFI_MEMORY_TYPE is defined in Section 6.2 , EFI_BOOT_SERVICES.AllocatePages() .
<i>Pages</i>	The number of pages to allocate.
<i>HostAddress</i>	A pointer to store the base system memory address of the allocated range.
<i>Attributes</i>	The requested bit mask of attributes for the allocated range. Only the attributes EFI_PCI_ATTRIBUTE_MEMORY_WRITE_COMBINE , EFI_PCI_ATTRIBUTE_MEMORY_CACHED , and EFI_PCI_ATTRIBUTE_DUAL_ADDRESS_CYCLE may be used with this function. If any other bits are set, then EFI_UNSUPPORTED is returned. This function may choose to ignore this bit mask. The EFI_PCI_ATTRIBUTE_MEMORY_WRITE_COMBINE , and EFI_PCI_ATTRIBUTE_MEMORY_CACHED attributes provide a hint to the implementation that may improve the performance of the calling driver. The implementation may choose any default for the memory attributes including write combining, cached, both, or neither as long as the allocated buffer can be seen equally by both the processor and the PCI bus master.

Description

The `AllocateBuffer()` function allocates pages that are suitable for an `EfiPciOperationBusMasterCommonBuffer` or `EfiPciOperationBusMasterCommonBuffer64` mapping. This means that the buffer allocated by this function must support simultaneous access by both the processor and a PCI Bus Master. The device address that the PCI Bus Master uses to access the buffer can be retrieved with a call to `Map()`.

If the `EFI_PCI_ATTRIBUTE_DUAL_ADDRESS_CYCLE` bit of `Attributes` is set, then when the buffer allocated by this function is mapped with a call to `Map()`, the device address that is returned by `Map()` must be within the 64-bit device address space of the PCI Bus Master.

If the `EFI_PCI_ATTRIBUTE_DUAL_ADDRESS_CYCLE` bit of `Attributes` is clear, then when the buffer allocated by this function is mapped with a call to `Map()`, the device address that is returned by `Map()` must be within the 32-bit device address space of the PCI Bus Master.

If the memory allocation specified by `MemoryType` and `Pages` cannot be satisfied, then `EFI_OUT_OF_RESOURCES` is returned.

Status Codes Returned

EFI_SUCCESS	The requested memory pages were allocated.
EFI_INVALID_PARAMETER	<code>MemoryType</code> is invalid.
EFI_INVALID_PARAMETER	<code>HostAddress</code> is NULL .
EFI_UNSUPPORTED	<code>Attributes</code> is unsupported. The only legal attribute bits are EFI_PCI_ATTRIBUTE_MEMORY_WRITE_COMBINE , EFI_PCI_ATTRIBUTE_MEMORY_CACHED , and EFI_PCI_ATTRIBUTE_DUAL_ADDRESS_CYCLE .
EFI_OUT_OF_RESOURCES	The memory pages could not be allocated.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.FreeBuffer()

Summary

Frees memory that was allocated with [AllocateBuffer\(\)](#).

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_FREE_BUFFER) (
    IN  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL  *This,
    IN  UINTN                             Pages,
    IN  VOID                             *HostAddress
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI ROOT BRIDGE IO PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Pages</i>	The number of pages to free.
<i>HostAddress</i>	The base system memory address of the allocated range.

Description

The **FreeBuffer()** function frees memory that was allocated with **AllocateBuffer()**.

Status Codes Returned

EFI_SUCCESS	The requested memory pages were freed.
EFI_INVALID_PARAMETER	The memory range specified by <i>HostAddress</i> and <i>Pages</i> was not allocated with AllocateBuffer() .

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Flush()

Summary

Flushes all PCI posted write transactions from a PCI host bridge to system memory.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_FLUSH) (
    IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL *This
);
```

Parameters

This A pointer to the [EFI PCI ROOT BRIDGE IO PROTOCOL](#). Type [EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL](#) is defined in [Section 13.2.1](#).

Description

The **Flush()** function flushes any PCI posted write transactions from a PCI host bridge to system memory. Posted write transactions are generated by PCI bus masters when they perform write transactions to target addresses in system memory.

This function does not flush posted write transactions from any PCI bridges. A PCI controller specific action must be taken to guarantee that the posted write transactions have been flushed from the PCI controller and from all the PCI bridges into the PCI host bridge. This is typically done with a PCI read transaction from the PCI controller prior to calling **Flush()**.

If the PCI controller specific action required to flush the PCI posted write transactions has been performed, and this function returns **EFI_SUCCESS**, then the PCI bus master's view and the processor's view of system memory are guaranteed to be coherent. If the PCI posted write transactions cannot be flushed from the PCI host bridge, then the PCI bus master and processor are not guaranteed to have a coherent view of system memory, and **EFI_DEVICE_ERROR** is returned.

Status Codes Returned

EFI_SUCCESS	The PCI posted write transactions were flushed from the PCI host bridge to system memory.
EFI_DEVICE_ERROR	The PCI posted write transactions were not flushed from the PCI host bridge due to a hardware error.

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.GetAttributes()

Summary

Gets the attributes that a PCI root bridge supports setting with [SetAttributes\(\)](#), and the attributes that a PCI root bridge is currently using.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_GET_ATTRIBUTES) (
    IN  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL  *This,
    OUT UINT64                          *Supports  OPTIONAL,
    OUT UINT64                          *Attributes OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI ROOT BRIDGE IO PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Supports</i>	A pointer to the mask of attributes that this PCI root bridge supports setting with SetAttributes() . The available attributes are listed in Section 13.2 . This is an optional parameter that may be NULL .
<i>Attributes</i>	A pointer to the mask of attributes that this PCI root bridge is currently using. The available attributes are listed in Section 13.2 . This is an optional parameter that may be NULL .

Description

The [GetAttributes\(\)](#) function returns the mask of attributes that this PCI root bridge supports and the mask of attributes that the PCI root bridge is currently using. If *Supports* is not **NULL**, then *Supports* is set to the mask of attributes that the PCI root bridge supports. If *Attributes* is not **NULL**, then *Attributes* is set to the mask of attributes that the PCI root bridge is currently using. If both *Supports* and *Attributes* are **NULL**, then **EFI_INVALID_PARAMETER** is returned. Otherwise, **EFI_SUCCESS** is returned.

If a bit is set in *Supports*, then the PCI root bridge supports this attribute type, and a call can be made to [SetAttributes\(\)](#) using that attribute type. If a bit is set in *Attributes*, then the PCI root bridge is currently using that attribute type. Since a PCI host bus may be composed of more than one PCI root bridge, different *Attributes* values may be returned by different PCI root bridges.

Status Codes Returned

EFI_SUCCESS	If <i>Supports</i> is not NULL , then the attributes that the PCI root bridge supports is returned in <i>Supports</i> . If <i>Attributes</i> is not NULL , then the attributes that the PCI root bridge is currently using is returned in <i>Attributes</i> .
EFI_INVALID_PARAMETER	Both <i>Supports</i> and <i>Attributes</i> are NULL .

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.SetAttributes()

Summary

Sets attributes for a resource range on a PCI root bridge.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_SET_ATTRIBUTES) (
    IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL  *This,
    IN UINT64                            Attributes,
    IN OUT UINT64                        *ResourceBase    OPTIONAL,
    IN OUT UINT64                        *ResourceLength  OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI ROOT BRIDGE IO PROTOCOL . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section 13.2 .
<i>Attributes</i>	The mask of attributes to set. If the attribute bit MEMORY_WRITE_COMBINE , MEMORY_CACHED , or MEMORY_DISABLE is set, then the resource range is specified by <i>ResourceBase</i> and <i>ResourceLength</i> . If MEMORY_WRITE_COMBINE , MEMORY_CACHED , and MEMORY_DISABLE are not set, then <i>ResourceBase</i> and <i>ResourceLength</i> are ignored, and may be NULL . The available attributes are listed in Section 13.2 .
<i>ResourceBase</i>	A pointer to the base address of the resource range to be modified by the attributes specified by <i>Attributes</i> . On return, <i>*ResourceBase</i> will be set the actual base address of the resource range. Not all resources can be set to a byte boundary, so the actual base address may differ from the one passed in by the caller. This parameter is only used if the MEMORY_WRITE_COMBINE bit, the MEMORY_CACHED bit, or the MEMORY_DISABLE bit of <i>Attributes</i> is set. Otherwise, it is ignored, and may be NULL .
<i>ResourceLength</i>	A pointer to the length of the resource range to be modified by the attributes specified by <i>Attributes</i> . On return, <i>*ResourceLength</i> will be set the actual length of the resource range. Not all resources can be set to a byte boundary, so the actual length may differ from the one passed in by the caller. This parameter is only used if the MEMORY_WRITE_COMBINE bit, the MEMORY_CACHED bit, or the MEMORY_DISABLE bit of <i>Attributes</i> is set. Otherwise, it is ignored, and may be NULL .

Description

The **SetAttributes ()** function sets the attributes specified in *Attributes* for the PCI root bridge on the resource range specified by *ResourceBase* and *ResourceLength*. Since the granularity of setting these attributes may vary from resource type to resource type, and from platform to platform, the actual resource range and the one passed in by the caller may differ. As a result, this function may set the attributes specified by *Attributes* on a larger resource range than the caller requested. The actual range is returned in *ResourceBase* and *ResourceLength*. The caller is responsible for verifying that the actual range for which the attributes were set is acceptable.

If the attributes are set on the PCI root bridge, then the actual resource range is returned in *ResourceBase* and *ResourceLength*, and **EFI_SUCCESS** is returned.

If the attributes specified by *Attributes* are not supported by the PCI root bridge, then **EFI_UNSUPPORTED** is returned. The set of supported attributes for a PCI root bridge can be found by calling [GetAttributes \(\)](#).

If either *ResourceBase* or *ResourceLength* are **NULL**, and a resource range is required for the attributes specified in *Attributes*, then **EFI_INVALID_PARAMETER** is returned.

If more than one resource range is required for the set of attributes specified by *Attributes*, then **EFI_INVALID_PARAMETER** is returned.

If there are not enough resources available to set the attributes, then **EFI_OUT_OF_RESOURCES** is returned.

Status Codes Returned

EFI_SUCCESS	The set of attributes specified by <i>Attributes</i> for the resource range specified by <i>ResourceBase</i> and <i>ResourceLength</i> were set on the PCI root bridge, and the actual resource range is returned in <i>ResourceBase</i> and <i>ResourceLength</i> .
EFI_UNSUPPORTED	A bit is set in <i>Attributes</i> that is not supported by the PCI Root Bridge. The supported attribute bits are reported by GetAttributes () .
EFI_INVALID_PARAMETER	More than one attribute bit is set in <i>Attributes</i> that requires a resource range.
EFI_INVALID_PARAMETER	A resource range is required, and <i>ResourceBase</i> is NULL .
EFI_INVALID_PARAMETER	A resource range is required, and <i>ResourceLength</i> is NULL .
EFI_OUT_OF_RESOURCES	There are not enough resources to set the attributes on the resource range specified by <i>BaseAddress</i> and <i>Length</i> .

EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Configuration()

Summary

Retrieves the current resource settings of this PCI root bridge in the form of a set of ACPI 2.0 resource descriptors.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_CONFIGURATION) (
    IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL *This,
    OUT VOID **Resources
);
```

Parameters

- This* A pointer to the [EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL](#). Type [EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL](#) is defined in [Section 13.2](#).
- Resources* A pointer to the ACPI 2.0 resource descriptors that describe the current configuration of this PCI root bridge. The storage for the ACPI 2.0 resource descriptors is allocated by this function. The caller must treat the return buffer as read-only data, and the buffer must not be freed by the caller. See “Related Definitions” for the ACPI 2.0 resource descriptors that may be used.

Related Definitions

There are only two resource descriptor types from the *ACPI Specification* that may be used to describe the current resources allocated to a PCI root bridge. These are the QWORD Address Space Descriptor (ACPI 2.0 Section 6.4.3.5.1), and the End Tag (ACPI 2.0 Section 6.4.2.8). The QWORD Address Space Descriptor can describe memory, I/O, and bus number ranges for dynamic or fixed resources. The configuration of a PCI root bridge is described with one or more QWORD Address Space Descriptors followed by an End Tag. [Table 28](#) and [Table 112](#) contains these two descriptor types. Please see the *ACPI Specification* for details on the field values. The definition of the Address Space Granularity field in the ACPI 2.0 QWORD Address Space Descriptor differs from the ACPI 2.0 Specification, and the definition in [Table 112](#) is that one that must be used.

Table 112. ACPI 2.0 QWORD Address Space Descriptor

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x8A	QWORD Address Space Descriptor
0x01	0x02	0x2B	Length of this descriptor in bytes not including the first two fields
0x03	0x01		Resource Type 0 – Memory Range 1 – I/O Range 2 – Bus Number Range

0x04	0x01		General Flags
0x05	0x01		Type Specific Flags
0x06	0x08		Address Space Granularity. Used to differentiate between a 32-bit memory request and a 64-bit memory request. For a 32-bit memory request, this field should be set to 32. For a 64-bit memory request, this field should be set to 64.

0x01	0x01	0x00	Checksum. If 0, then checksum is assumed to be valid.

Description

The **Configuration()** function retrieves a set of ACPI 2.0 resource descriptors that contains the current configuration of this PCI root bridge. If the current configuration can be retrieved, then it is returned in *Resources* and **EFI_SUCCESS** is returned. See “Related Definitions” below for the resource descriptor types that are supported by this function. If the current configuration cannot be retrieved, then **EFI_UNSUPPORTED** is returned.

Status Codes Returned

EFI_SUCCESS	The current configuration of this PCI root bridge was returned in <i>Resources</i> .
EFI_UNSUPPORTED	The current configuration of this PCI root bridge could not be retrieved.

13.2.1 PCI Root Bridge Device Paths

An [EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL](#) must be installed on a handle for its services to be available to drivers. In addition to the [EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL](#), an [EFI_DEVICE_PATH_PROTOCOL](#) must also be installed on the same handle. See [Section 9](#) for a detailed description of [EFI_DEVICE_PATH_PROTOCOL](#).

Typically, an ACPI Device Path Node is used to describe a PCI Root Bridge. Depending on the bus hierarchy in the system, additional device path nodes may precede this ACPI Device Path Node. A desktop system will typically contain only one PCI Root Bridge, so there would be one handle with a [EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL](#) and an [EFI_DEVICE_PATH_PROTOCOL](#). A server system may contain multiple PCI Root Bridges, so it would contain a handle for each PCI Root Bridge present, and on each of those handles would be an [EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL](#) and an [EFI_DEVICE_PATH_PROTOCOL](#). In all

cases, the contents of the ACPI Device Path Nodes for PCI Root Bridges must match the information present in the ACPI tables for that system.

[Table 114](#) shows an example device path for a PCI Root Bridge in a desktop system. Today, a desktop system typically contains one PCI Root Bridge. This device path consists of an ACPI Device Path Node, and a Device Path End Structure. The `_HID` and `_UID` must match the ACPI table description of the PCI Root Bridge. For a system with only one PCI Root Bridge, the `_UID` value is usually 0x0000. The shorthand notation for this device path is **ACPI (PNP0A03, 0)**.

Table 114. PCI Root Bridge Device Path for a Desktop System

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	<code>_HID</code> PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	<code>_UID</code>
0x0C	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x0D	0x01	0xFF	Sub type – End of Entire Device Path
0x0E	0x02	0x04	Length – 0x04 bytes

[Table 115](#) through [Table 118](#) show example device paths for the PCI Root Bridges in a server system with four PCI Root Bridges. Each of these device paths consists of an ACPI Device Path Node, and a Device Path End Structure. The `_HID` and `_UID` must match the ACPI table description of the PCI Root Bridges. The only difference between each of these device paths is the `_UID` field. The shorthand notation for these four device paths is **ACPI (PNP0A03, 0)**, **ACPI (PNP0A03, 1)**, **ACPI (PNP0A03, 2)**, and **ACPI (PNP0A03, 3)**.

Table 115. PCI Root Bridge Device Path for Bridge #0 in a Server System

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path

0x11	0x01	0xFF	Sub type – End of Entire Device Path
0x12	0x02	0x04	Length – 0x04 bytes

13.3 PCI Driver Model

[Section 13.3](#) and [Section 13.4](#) describe the PCI Driver Model. This includes the behavior of PCI Bus Drivers, the behavior of a PCI Device Drivers, and a detailed description of the PCI I/O Protocol. The PCI Bus Driver manages PCI buses present in a system, and PCI Device Drivers manage PCI controllers present on PCI buses. The PCI Device Drivers produce an I/O abstraction that can be used to boot an EFI compliant operating system.

This document provides enough material to implement a PCI Bus Driver, and the tools required to design and implement a PCI Device Drivers. It does not provide any information on specific PCI devices.

The material contained in this section is designed to extend this specification and the *UEFI Driver Model* in a way that supports PCI device drivers and PCI bus drivers. These extensions are provided in the form of PCI-specific protocols. This section provides the information required to implement a PCI Bus Driver in system firmware. The section also contains the information required by driver writers to design and implement PCI Device Drivers that a platform may need to boot a UEFI-compliant OS.

The PCI Driver Model described here is intended to be a foundation on which a PCI Bus Driver and a wide variety of PCI Device Drivers can be created.

13.3.1 PCI Driver Initialization

There are very few differences between a PCI Bus Driver and PCI Device Driver in the entry point of the driver. The file for a driver image must be loaded from some type of media. This could include ROM, FLASH, hard drives, floppy drives, CD-ROM, or even a network connection. Once a driver image has been found, it can be loaded into system memory with the Boot Service [EFI_BOOT_SERVICES.LoadImage\(\)](#). **LoadImage()** loads a PE/COFF formatted image into system memory. A handle is created for the driver, and a Loaded Image Protocol instance is placed on that handle. A handle that contains a Loaded Image Protocol instance is called an *Image Handle*. At this point, the driver has not been started. It is just sitting in memory waiting to be started. [Figure 37](#) shows the state of an image handle for a driver after **LoadImage()** has been called.

OM13148

Figure 37. Image Handle

After a driver has been loaded with the Boot Service [EFI_BOOT_SERVICES.LoadImage\(\)](#), it must be started with the Boot Service [EFI_BOOT_SERVICES.StartImage\(\)](#). This is true of all types of applications and drivers that can be loaded and started on a UEFI compliant system. The entry point for a driver that follows the UEFI Driver Model must follow some strict rules. First, it is not allowed to touch any hardware. Instead, it is only allowed to install protocol instances onto its own *Image Handle*. A driver that follows the UEFI Driver Model is *required* to install an instance of the Driver Binding Protocol onto its own *Image Handle*. It may optionally install the Driver Diagnostics Protocol or the Component Name Protocol. In addition, if a driver wishes to be unloadable it may optionally update the Loaded Image Protocol to provide its own [Unload\(\)](#) function. Finally, if a driver needs to perform any special operations when the Boot Service [EFI_BOOT_SERVICES](#) is called, it may optionally create an event with a notification function that is triggered when the Boot Service **ExitBootServices()** is called. An *Image Handle* that contains a Driver Binding Protocol instance is known as a *Driver Image Handle*. [Figure 38](#) shows a possible configuration for the *Image Handle* from [Figure 37](#) after the Boot Service **StartImage()** has been called.

Figure 38. PCI Driver Image Handle

13.3.1.1 Driver Diagnostics Protocol

If a PCI Bus Driver or a PCI Device Driver requires diagnostics, then an [EFI DRIVER DIAGNOSTICS2 PROTOCOL](#) must be installed on the image handle in the entry point for the driver. This protocol contains functions to perform diagnostics on a controller. The [EFI_DRIVER_DIAGNOSTICS2_PROTOCOL](#) is not allowed to interact with the user. Instead, it must return status information through a buffer. The functions of this protocol will be invoked by a platform management utility.

13.3.1.2 Component Name Protocol

Both a PCI Bus Driver and a PCI Device Driver are able to produce user readable names for the PCI drivers and/or the set of PCI controllers that the PCI drivers are managing. This is accomplished by installing an instance of the [EFI COMPONENT_NAME2 PROTOCOL](#) on the image handle of the driver. This protocol can produce driver and controller names in the form of a string in one of several languages. This protocol can be used by a platform management utility to display user readable names for the drivers and controllers present in a system. Please see the *EFI Driver Model Specification* for details on the [EFI_COMPONENT_NAME2_PROTOCOL](#).

13.3.1.3 Driver Family Override Protocol

If a PCI Bus Driver or PCI Device Driver always wants the PCI driver delivered in a PCI Option ROM to manage the PCI controller associated with the PCI Option ROM, then the Driver Family Override Protocol must not be produced.

If a PCI Bus Driver or PCI Device Driver always wants the PCI driver with the highest Version value in the Driver Binding Protocol to manage all the PCI Controllers in the same family of PCI controllers, then the Driver Family Override Protocol must be produced on the same handle as the Driver Binding Protocol.

13.3.2 PCI Bus Drivers

A PCI Bus Driver manages PCI Host Bus Controllers that can contain one or more PCI Root Bridges. [Figure 39](#) shows an example of a desktop system that has one PCI Host Bus Controller with one PCI Root Bridge.

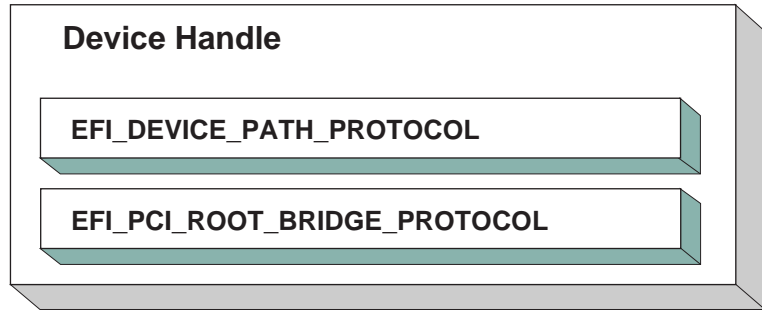

Figure 39. PCI Host Bus Controller

The PCI Host Bus Controller in [Figure 39](#) is abstracted in software with the PCI Root Bridge I/O Protocol. A PCI Bus Driver will manage handles that contain this protocol. [Figure 40](#) shows an example device handle for a PCI Host Bus Controller. It contains a Device Path Protocol instance and a PCI Root Bridge I/O Protocol Instance.

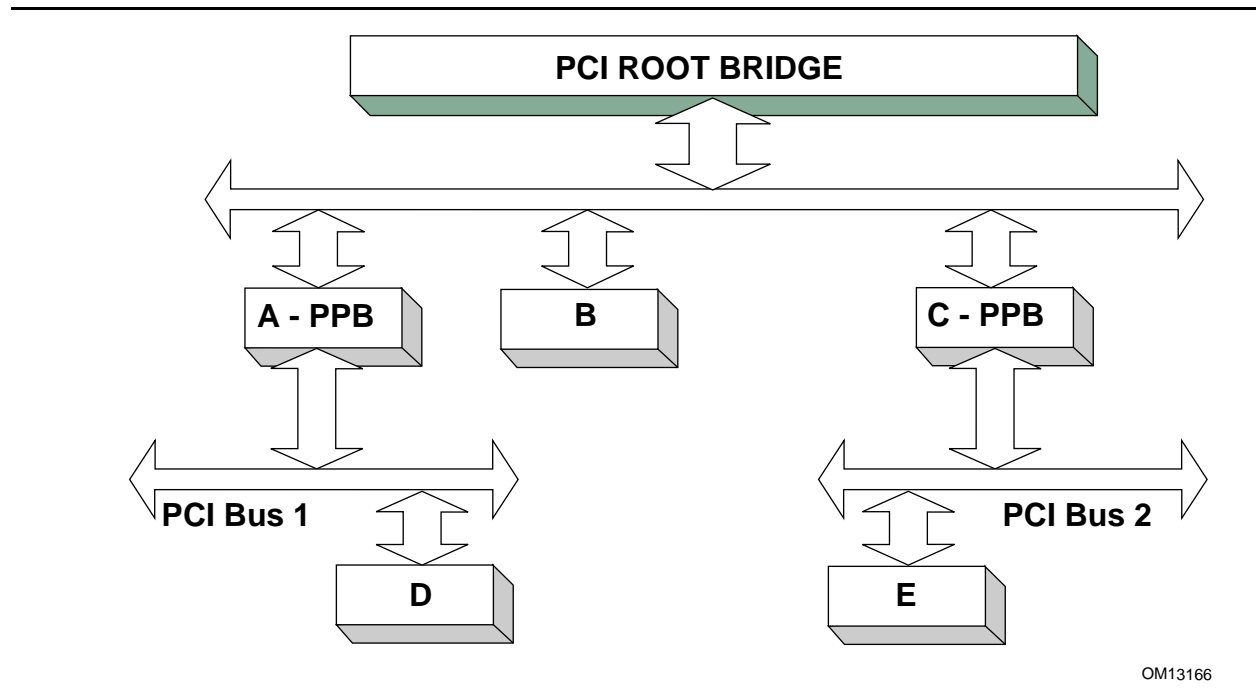

OM13151

Figure 40. Device Handle for a PCI Host Bus Controller

13.3.2.1 Driver Binding Protocol for PCI Bus Drivers

The Driver Binding Protocol contains three services. These are [Supported\(\)](#), [Start\(\)](#), and [Stop\(\)](#). **Supported()** tests to see if the PCI Bus Driver can manage a device handle. A PCI Bus Driver can only manage device handles that contain the Device Path Protocol and the PCI Root Bridge I/O Protocol, so a PCI Bus Driver must look for these two protocols on the device handle that is being tested.

The **Start()** function tells the PCI Bus Driver to start managing a device handle. The device handle should support the protocols shown in [Figure 40](#). The PCI Root Bridge I/O Protocols provides access to the PCI I/O, PCI Memory, PCI Prefetchable Memory, and PCI DMA functions. The PCI Controllers behind a PCI Root Bridge may exist on one or more PCI Buses. The standard mechanism for expanding the number of PCI Buses on a single PCI Root Bridge is to use PCI to PCI Bridges. Once a PCI Enumerator configures these bridges, they are invisible to software. As a result, the PCI Bus Driver flattens the PCI Bus hierarchy when it starts managing a device handle that represents a PCI Host Controller. [Figure 41](#) shows the physical tree structure for a set of PCI Device denoted by A, B, C, D, and E. Device A and C are PCI to PCI Bridges.

OM13166

Figure 41. Physical PCI Bus Structure

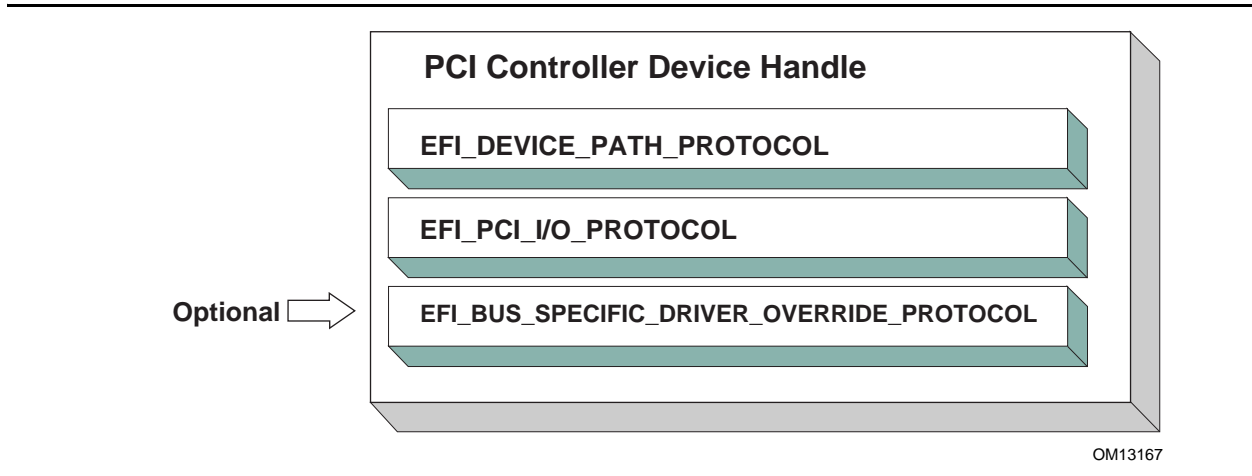

[Figure 42](#) shows the tree structure generated by a PCI Bus Driver before and after **Start()** is called. This is a logical view of set of PCI controller, and not a physical view. The physical tree is flattened, so any PCI to PCI bridge devices are invisible. In this example, the PCI Bus Driver finds the five child PCI Controllers on the PCI Bus from [Figure 41](#). A device handle is created for every PCI Controller including all the PCI to PCI Bridges. The arrow with the dashed line coming into the PCI Host Bus Controller represents a link to the PCI Host Bus Controller's parent. If the PCI Host Bus Controller is a Root Bus Controller, then it will not have a parent. The PCI Driver Model does not require that a PCI Host Bus Controller be a Root Bus Controller. A PCI Host Bus Controller can be present at any location in the tree, and the PCI Bus Driver should be able to manage the PCI Host Bus Controller.

OM13153

Figure 42. Connecting a PCI Bus Driver

The PCI Bus Driver has the option of creating all of its children in one call to [Start\(\)](#), or spreading it across several calls to **Start()**. In general, if it is possible to design a bus driver to create one child at a time, it should do so to support the rapid boot capability in the UEFI Driver Model. Each of the child device handles created in **Start()** must contain a Device Path Protocol instance, a PCI I/O protocol instance, and optionally a Bus Specific Driver Override Protocol instance. The PCI I/O Protocol is described in [Section 13.4](#). The format of device paths for PCI Controllers is described in Section 2.6, and details on the Bus Specific Driver Override Protocol can be found in the *EFI Driver Model Specification*. [Figure 43](#) shows an example child device handle that is created by a PCI Bus Driver for a PCI Controller.

OM13167

Figure 43. Child Handle Created by a PCI Bus Driver

A PCI Bus Driver must perform several steps to manage a PCI Host Bus Controller, as follows:

- Initialize the PCI Host Bus Controller.

- If the PCI buses have not been initialized by a previous agent, perform PCI Enumeration on all the PCI Root Bridges that the PCI Host Bus Controller contains. This involves assigning a PCI bus number, allocating PCI I/O resources, PCI Memory resources, and PCI Prefetchable Memory resources.
- Discover all the PCI Controllers on all the PCI Root Bridges. If a PCI Controller is a PCI to PCI Bridge, then the I/O, Memory, and Bus Master bits in the Control register of the PCI Configuration Header should be placed in the enabled state. The PCI Bus Driver should disable the I/O, Memory, and Bus Master bits for PCI Controllers that respond to legacy ISA resources (e.g. VGA). It is a PCI Device Driver's responsibility to enable the I/O, Memory, and Bus Master bits (if they are not already enabled by the PCI bus driver) of the Control register as required with a call to the [Attributes \(\)](#) service when the PCI Device Driver is started. A similar call to the [Attributes \(\)](#) service should be made when the PCI Device Driver is stopped to restore original [Attributes \(\)](#) state, including the I/O, Memory, and Bus Master bits of the Control register.
- Create a device handle for each PCI Controller found. If a request is being made to start only one PCI Controller, then only create one device handle.
- Install a Device Path Protocol instance and a PCI I/O Protocol instance on the device handle created for each PCI Controller.
- If the PCI Controller has a PCI Option ROM, then allocate a memory buffer that is the same size as the PCI Option ROM, and copy the PCI Option ROM contents to the memory buffer.
- If the PCI Option ROM contains any UEFI drivers, then attach a Bus Specific Driver Override Protocol to the device handle of the PCI Controller that is associated with the PCI Option ROM.

The [Stop \(\)](#) function tells the PCI Bus Driver to stop managing a PCI Host Bus Controller. The [Stop \(\)](#) function can destroy one or more of the device handles that were created on a previous call to [Start \(\)](#). If all of the child device handles have been destroyed, then [Stop \(\)](#) will place the PCI Host Bus Controller in a quiescent state. The functionality of [Stop \(\)](#) mirrors [Start \(\)](#), as follows:

1. Complete all outstanding transactions to the PCI Host Bus Controller.
2. If the PCI Host Bus Controller is being stopped, then place it in a quiescent state.
3. If one or more child handles are being destroyed, then:
 - a. Uninstall all the protocols from the device handles for the PCI Controllers found in [Start \(\)](#).
 - b. Free any memory buffers allocated for PCI Option ROMs.
 - c. Destroy the device handles for the PCI controllers created in [Start \(\)](#).

13.3.2.2 PCI Enumeration

The PCI Enumeration process is a platform-specific operation that depends on the properties of the chipset that produces the PCI bus. As a result, details on PCI Enumeration are outside the scope of this document. A PCI Bus Driver requires that PCI Enumeration has been performed, so it either needs to have been done prior to the PCI Bus Driver starting, or it must be part of the PCI Bus Driver's implementation.

13.3.3 PCI Device Drivers

PCI Device Drivers manage PCI Controllers. Device handles for PCI Controllers are created by PCI Bus Drivers. A PCI Device Driver is not allowed to create any new device handles. Instead, it attaches protocol instance to the device handle of the PCI Controller. These protocol instances are I/O abstractions that allow the PCI Controller to be used in the preboot environment. The most common I/O abstractions are used to boot an EFI compliant OS.

13.3.3.1 Driver Binding Protocol for PCI Device Drivers

The Driver Binding Protocol contains three services. These are [Supported\(\)](#), [Start\(\)](#), and [Stop\(\)](#). **Supported()** tests to see if the PCI Device Driver can manage a device handle. A PCI Device Driver can only manage device handles that contain the Device Path Protocol and the PCI I/O Protocol, so a PCI Device Driver must look for these two protocols on the device handle that is being tested. In addition, it needs to check to see if the device handle represents a PCI Controller that the PCI Device Driver knows how to manage. This is typically done by using the services of the PCI I/O Protocol to read the PCI Configuration Header for the PCI Controller, and looking at the *VendorId*, *DeviceId*, and *SubsystemId* fields.

The **Start()** function tells the PCI Device Driver to start managing a PCI Controller. A PCI Device Driver is not allowed to create any new device handles. Instead, it installs one or more addition protocol instances on the device handle for the PCI Controller. A PCI Device Driver is not allowed to modify the resources allocated to a PCI Controller. These resource allocations are owned by the PCI Bus Driver or some other firmware component that initialized the PCI Bus prior to the execution of the PCI Bus Driver. This means that the PCI BARs (Base Address Registers) and the configuration of any PCI to PCI bridge controllers must not be modified by a PCI Device Driver. A PCI Bus Driver will leave a PCI Device in a disabled safe initial state. A PCI Device Driver should save the original **Attributes()** state. It is a PCI Device Driver's responsibility to call **Attributes()** to enable the I/O, Memory, and Bus Master decodes if they are not already enabled by the PCI bus driver.

The [Stop\(\)](#) function mirrors the [Start\(\)](#) function, so the **Stop()** function completes any outstanding transactions to the PCI Controller and removes the protocol interfaces that were installed in **Start()**. [Figure 44](#) shows the device handle for a PCI Controller before and after **Start()** is called. In this example, a PCI Device Driver is adding the Block I/O Protocol to the device handle for the PCI Controller. It is also a PCI Device Driver's responsibility to restore original **Attributes()** state, including the I/O, Memory, and Bus Master decodes by calling [Attributes\(\)](#).

Figure 44. Connecting a PCI Device Driver

13.4 EFI PCI I/O Protocol

This section provides a detailed description of the [EFI PCI IO PROTOCOL](#). This protocol is used by code, typically drivers, running in the EFI boot services environment to access memory and I/O on a PCI controller. In particular, functions for managing devices on PCI buses are defined here.

The interfaces provided in the [EFI_PCI_IO_PROTOCOL](#) are for performing basic operations to memory, I/O, and PCI configuration space. The system provides abstracted access to basic system resources to allow a driver to have a programmatic method to access these basic system resources. The main goal of this protocol is to provide an abstraction that simplifies the writing of device drivers for PCI devices. This goal is accomplished by providing the following features:

- A driver model that does not require the driver to search the PCI busses for devices to manage. Instead, drivers are provided the location of the device to manage or have the capability to be notified when a PCI controller is discovered.
- A device driver model that abstracts the I/O addresses, Memory addresses, and PCI Configuration addresses from the PCI device driver. Instead, BAR (Base Address Register) relative addressing is used for I/O and Memory accesses, and device relative addressing is used for PCI Configuration accesses. The BAR relative addressing is specified in the PCI I/O services as a BAR index. A PCI controller may contain a combination of 32-bit and 64-bit

BARs. The BAR index represents the logical BAR number in the standard PCI configuration header starting from the first BAR. The BAR index does not represent an offset into the standard PCI Configuration Header because those offsets will vary depending on the combination and order of 32-bit and 64-bit BARs.

- The Device Path for the PCI device can be obtained from the same device handle that the **EFI_PCI_IO_PROTOCOL** resides.
- The PCI Segment, PCI Bus Number, PCI Device Number, and PCI Function Number of the PCI device if they are required. The general idea is to abstract these details away from the PCI device driver. However, if these details are required, then they are available.
- Details on any nonstandard address decoding that is not covered by the PCI device's Base Address Registers.
- Access to the PCI Root Bridge I/O Protocol for the PCI Host Bus for which the PCI device is a member.
- A copy of the PCI Option ROM if it is present in system memory.
- Functions to perform bus mastering DMA. This includes both packet based DMA and common buffer DMA.

EFI_PCI_IO_PROTOCOL

Summary

Provides the basic Memory, I/O, PCI configuration, and DMA interfaces that a driver uses to access its PCI controller.

GUID

```
#define EFI_PCI_IO_PROTOCOL_GUID \
    {0x4cf5b200,0x68b8,0x4ca5,\
     {0x9e,0xec,0xb2,0x3e,0x3f,0x50,0x02,0x9a}}
```

Protocol Interface Structure

```
typedef struct _EFI_PCI_IO_PROTOCOL {
    EFI_PCI_IO_PROTOCOL_POLL_IO_MEM      PollMem;
    EFI_PCI_IO_PROTOCOL_POLL_IO_MEM      PollIo;

} EFI_PCI_IO_PROTOCOL;
```

Parameters

<i>PollMem</i>	Polls an address in PCI memory space until an exit condition is met, or a timeout occurs. See the PollMem() function description.
<i>PollIo</i>	Polls an address in PCI I/O space until an exit condition is met, or a timeout occurs. See the PollIo() function description.
<i>Mem.Read</i>	Allows BAR relative reads to PCI memory space. See the Mem.Read() function description.
<i>Mem.Write</i>	Allows BAR relative writes to PCI memory space. See the Mem.Write() function description.
<i>Io.Read</i>	Allows BAR relative reads to PCI I/O space. See the Io.Read() function description.
<i>Io.Write</i>	Allows BAR relative writes to PCI I/O space. See the Io.Write() function description.
<i>Pci.Read</i>	Allows PCI controller relative reads to PCI configuration space. See the Pci.Read() function description.
<i>Pci.Write</i>	Allows PCI controller relative writes to PCI configuration space. See the Pci.Write() function description.

<i>CopyMem</i>	Allows one region of PCI memory space to be copied to another region of PCI memory space. See the CopyMem() function description.
<i>Map</i>	Provides the PCI controller–specific address needed to access system memory for DMA. See the Map() function description.
<i>Unmap</i>	Releases any resources allocated by Map() . See the Unmap() function description.
<i>AllocateBuffer</i>	Allocates pages that are suitable for a common buffer mapping. See the AllocateBuffer() function description.
<i>FreeBuffer</i>	Frees pages that were allocated with AllocateBuffer() . See the FreeBuffer() function description.
<i>Flush</i>	Flushes all PCI posted write transactions to system memory. See the Flush() function description.
<i>GetLocation</i>	Retrieves this PCI controller’s current PCI bus number, device number, and function number. See the GetLocation() function description.
<i>Attributes</i>	Performs an operation on the attributes that this PCI controller supports. The operations include getting the set of supported attributes, retrieving the current attributes, setting the current attributes, enabling attributes, and disabling attributes. See the Attributes() function description.
<i>GetBarAttributes</i>	Gets the attributes that this PCI controller supports setting on a BAR using SetBarAttributes() , and retrieves the list of resource descriptors for a BAR. See the GetBarAttributes() function description.
<i>SetBarAttributes</i>	Sets the attributes for a range of a BAR on a PCI controller. See the SetBarAttributes() function description.
<i>RomSize</i>	The size, in bytes, of the ROM image.
<i>RomImage</i>	A pointer to the in memory copy of the ROM image. The PCI Bus Driver is responsible for allocating memory for the ROM image, and copying the contents of the ROM to memory. The contents of this buffer are either from the PCI option ROM that can be accessed through the ROM BAR of the PCI controller, or it is from a platform-specific location. The Attributes() function can be used to determine from which of these two sources the <i>RomImage</i> buffer was initialized.

EFI_PCI_IO_ATTRIBUTE_ISA_IO_16

If this bit is set, then the PCI I/O cycles between 0x100 and 0x3FF are forwarded to the PCI controller using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for legacy ISA devices. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles. This bit may not be combined with

EFI_PCI_IO_ATTRIBUTE_ISA_IO.

EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO_16

If this bit is set, then the PCI I/O write cycles for 0x3C6, 0x3C8, and 0x3C9 are forwarded to the PCI controller using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O write cycles to the VGA palette registers on a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles. This bit may not be combined with

EFI_PCI_IO_ATTRIBUTE_VGA_IO or **EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO.**

EFI_PCI_IO_ATTRIBUTE_VGA_IO_16

If this bit is set, then the PCI I/O cycles in the ranges 0x3B0–0x3BB and 0x3C0–0x3DF are forwarded to the PCI controller using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a VGA controller to a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles. This bit may not be combined with

EFI_PCI_IO_ATTRIBUTE_VGA_IO or **EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO.** Because **EFI_PCI_IO_ATTRIBUTE_VGA_IO_16** also includes the I/O range described by **EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO_16**, the **EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO_16** bit is ignored if **EFI_PCI_IO_ATTRIBUTE_VGA_IO_16** is set.

EFI_PCI_IO_ATTRIBUTE_ISA_MOTHERBOARD_IO

If this bit is set, then the PCI I/O cycles between 0x00000000 and 0x000000FF are forwarded to the PCI controller. This bit is used to forward I/O cycles for ISA motherboard devices. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles.

EFI_PCI_IO_ATTRIBUTE_ISA_IO

If this bit is set, then the PCI I/O cycles between 0x100 and 0x3FF are forwarded to the PCI controller using a 10-bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and address bits 16..31 must be zero. This bit is used to forward I/O cycles for legacy ISA devices. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles.

EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO

If this bit is set, then the PCI I/O write cycles for 0x3C6, 0x3C8, and 0x3C9 are forwarded to the PCI controller using a 10-bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and address bits 16..31 must be zero. This bit is used to forward I/O write cycles to the VGA palette registers on a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles.

EFI_PCI_IO_ATTRIBUTE_VGA_MEMORY

If this bit is set, then the PCI memory cycles between 0xA000 and 0xBFFF are forwarded to the PCI controller. This bit is used to forward memory cycles for a VGA frame buffer on a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI Memory cycles.

EFI_PCI_IO_ATTRIBUTE_VGA_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x3B0-0x3BB and 0x3C0-0x3DF are forwarded to the PCI controller using a 10-bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and the address bits 16..31 must be zero. This bit is used to forward I/O cycles for a VGA controller to a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles. Since **EFI_PCI_IO_ATTRIBUTE_VGA_IO** also includes the I/O range described by

EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO, the **EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO** bit is ignored if **EFI_PCI_IO_ATTRIBUTE_VGA_IO** is set.

EFI_PCI_IO_ATTRIBUTE_IDE_PRIMARY_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x1F0-0x1F7 and 0x3F6-0x3F7 are forwarded to a PCI controller using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a Primary IDE controller to a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles.

EFI_PCI_IO_ATTRIBUTE_IDE_SECONDARY_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x170-0x177 and 0x376-0x377 are forwarded to a PCI controller using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a

Secondary IDE controller to a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles.

EFI_PCI_IO_ATTRIBUTE_MEMORY_WRITE_COMBINE

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is accessed in a write combining mode. This bit is used to improve the write performance to a memory buffer on a PCI controller. By default, PCI memory ranges are not accessed in a write combining mode.

EFI_PCI_IO_ATTRIBUTE_MEMORY_CACHED

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is accessed in a cached mode. By default, PCI memory ranges are accessed noncached.

EFI_PCI_IO_ATTRIBUTE_IO

If this bit is set, then the PCI device will decode the PCI I/O cycles that the device is configured to decode.

EFI_PCI_IO_ATTRIBUTE_MEMORY

If this bit is set, then the PCI device will decode the PCI Memory cycles that the device is configured to decode.

EFI_PCI_IO_ATTRIBUTE_BUS_MASTER

If this bit is set, then the PCI device is allowed to act as a bus master on the PCI bus.

EFI_PCI_IO_ATTRIBUTE_MEMORY_DISABLE

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is disabled, and can no longer be accessed. By default, all PCI memory ranges are enabled.

EFI_PCI_IO_ATTRIBUTE_EMBEDDED_DEVICE

If this bit is set, then the PCI controller is an embedded device that is typically a component on the system board. If this bit is clear, then this PCI controller is part of an adapter that is populating one of the systems PCI slots.

EFI_PCI_IO_ATTRIBUTE_EMBEDDED_ROM

If this bit is set, then the PCI option ROM described by the *RomImage* and *RomSize* fields is not from ROM BAR of the PCI controller. If this bit is clear, then the *RomImage* and *RomSize* fields were initialized based on the PCI option ROM found through the ROM BAR of the PCI controller.

EFI_PCI_IO_ATTRIBUTE_DUAL_ADDRESS_CYCLE

If this bit is set, then the PCI controller is capable of producing PCI Dual Address Cycles, so it is able to access a 64-bit address space. If this bit is not set, then the PCI controller is not capable of producing PCI Dual Address Cycles, so it is only able to access a 32-bit address space.

If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are capable of producing PCI Dual Address Cycles. If any of them is not capable of producing PCI Dual

Address Cycles, attempt to perform Set or Enable operation using `Attributes()` function with this bit set will fail with the `EFI_UNSUPPORTED` error code.

```

//*****
// EFI_PCI_IO_PROTOCOL_OPERATION
//*****
typedef enum {
    EfiPciIoOperationBusMasterRead,
    EfiPciIoOperationBusMasterWrite,
    EfiPciIoOperationBusMasterCommonBuffer,
    EfiPciIoOperationMaximum
} EFI_PCI_IO_PROTOCOL_OPERATION;

```

EfiPciIoOperationBusMasterRead

A read operation from system memory by a bus master.

EfiPciIoOperationBusMasterWrite

A write operation to system memory by a bus master.

EfiPciIoOperationBusMasterCommonBuffer

Provides both read and write access to system memory by both the processor and a bus master. The buffer is coherent from both the processor's and the bus master's point of view.

Description

The `EFI_PCI_IO_PROTOCOL` provides the basic Memory, I/O, PCI configuration, and DMA interfaces that are used to abstract accesses to PCI controllers. There is one `EFI_PCI_IO_PROTOCOL` instance for each PCI controller on a PCI bus. A device driver that wishes to manage a PCI controller in a system will have to retrieve the `EFI_PCI_IO_PROTOCOL` instance that is associated with the PCI controller. A device handle for a PCI controller will minimally contain an [EFI_DEVICE_PATH_PROTOCOL](#) instance and an `EFI_PCI_IO_PROTOCOL` instance.

Bus mastering PCI controllers can use the DMA services for DMA operations. There are three basic types of bus mastering DMA that is supported by this protocol. These are DMA reads by a bus master, DMA writes by a bus master, and common buffer DMA. The DMA read and write operations may need to be broken into smaller chunks. The caller of [Map\(\)](#) must pay attention to the number of bytes that were mapped, and if required, loop until the entire buffer has been transferred. The following is a list of the different bus mastering DMA operations that are supported, and the sequence of `EFI_PCI_IO_PROTOCOL` interfaces that are used for each DMA operation type.

DMA Bus Master Read Operation

Call [Map\(\)](#) for `EfiPciIoOperationBusMasterRead`.

Program the DMA Bus Master with the `DeviceAddress` returned by `Map()`.

Start the DMA Bus Master.

Wait for DMA Bus Master to complete the read operation.

Call [Unmap\(\)](#).

DMA Bus Master Write Operation

Call Map() for EfiPciOperationBusMasterWrite.

Program the DMA Bus Master with the *DeviceAddress* returned by **Map()**.

Start the DMA Bus Master.

Wait for DMA Bus Master to complete the write operation.

Perform a PCI controller specific read transaction to flush all PCI write buffers (See *PCI Specification* Section 3.2.5.2).

Call [Flush\(\)](#).

Call **Unmap()**.

DMA Bus Master Common Buffer Operation

Call [AllocateBuffer\(\)](#) to allocate a common buffer.

Call Map() for EfiPciIoOperationBusMasterCommonBuffer.

Program the DMA Bus Master with the *DeviceAddress* returned by **Map()**.

The common buffer can now be accessed equally by the processor and the DMA bus master.

Call Unmap().

Call [FreeBuffer\(\)](#).

EFI_PCI_IO_PROTOCOL.PollMem()

Summary

Reads from the memory space of a PCI controller. Returns when either the polling exit criteria is satisfied or after a defined duration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_POLL_IO_MEM) (
    IN  EFI_PCI_IO_PROTOCOL      *This,
    IN  EFI_PCI_IO_PROTOCOL_WIDTH Width,
    IN  UINT8                    BarIndex,
    IN  UINT64                   Offset,
    IN  UINT64                   Mask,
    IN  UINT64                   Value,
    IN  UINT64                   Delay,
    OUT UINT64                   *Result
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI IO PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Width</i>	Signifies the width of the memory operations. Type EFI_PCI_IO_PROTOCOL_WIDTH is defined in Section 13.4 .
<i>BarIndex</i>	The BAR index of the standard PCI Configuration header to use as the base address for the memory operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value EFI_PCI_IO_PASS_THROUGH_BAR can be used to bypass the BAR relative addressing and pass <i>Offset</i> to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in Section 13.4 .
<i>Offset</i>	The offset within the selected BAR to start the memory operation.
<i>Mask</i>	Mask used for the polling criteria. Bytes above <i>Width</i> in <i>Mask</i> are ignored. The bits in the bytes below <i>Width</i> which are zero in <i>Mask</i> are ignored when polling the memory address.
<i>Value</i>	The comparison value used for the polling exit criteria.
<i>Delay</i>	The number of 100 ns units to poll. Note that timer available may be of poorer granularity.
<i>Result</i>	Pointer to the last value read from the memory location.

Description

This function provides a standard way to poll a PCI memory location. A PCI memory read operation is performed at the PCI memory address specified by *BarIndex* and *Offset* for the width specified by *Width*. The result of this PCI memory read operation is stored in *Result*. This PCI memory read operation is repeated until either a timeout of *Delay* 100 ns units has expired, or (*Result & Mask*) is equal to *Value*.

This function will always perform at least one memory access no matter how small *Delay* may be. If *Delay* is 0, then *Result* will be returned with a status of **EFI_SUCCESS** even if *Result* does not match the exit criteria. If *Delay* expires, then **EFI_TIMEOUT** is returned.

If *Width* is not **EfiPciIoWidthUint8**, **EfiPciIoWidthUint16**, **EfiPciIoWidthUint32**, or **EfiPciIoWidthUint64**, then **EFI_INVALID_PARAMETER** is returned.

The memory operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and memory width restrictions that a PCI controller on a platform might require. For example on some platforms, width requests of **EfiPciIoWidthUint64** do not work.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns. However, if the memory mapped I/O region being accessed by this function has the **EFI_PCI_ATTRIBUTE_MEMORY_CACHED** attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The last data returned from the access matched the poll exit criteria.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid.
EFI_INVALID_PARAMETER	<i>Result</i> is NULL .
EFI_UNSUPPORTED	<i>BarIndex</i> not valid for this PCI controller.
EFI_UNSUPPORTED	<i>Offset</i> is not valid for the <i>BarIndex</i> of this PCI controller.
EFI_TIMEOUT	<i>Delay</i> expired before a match occurred.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_IO_PROTOCOL.PollIo()

Summary

Reads from the I/O space of a PCI controller. Returns when either the polling exit criteria is satisfied or after a defined duration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_POLL_IO_MEM) (
    IN  EFI_PCI_IO_PROTOCOL      *This,
    IN  EFI_PCI_IO_PROTOCOL_WIDTH Width,
    IN  UINT8                    BarIndex,
    IN  UINT64                   Offset,
    IN  UINT64                   Mask,
    IN  UINT64                   Value,
    IN  UINT64                   Delay,
    OUT UINT64                   *Result
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI IO PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Width</i>	Signifies the width of the I/O operations. Type EFI_PCI_IO_PROTOCOL_WIDTH is defined in Section 13.4 .
<i>BarIndex</i>	The BAR index of the standard PCI Configuration header to use as the base address for the I/O operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value EFI_PCI_IO_PASS_THROUGH_BAR can be used to bypass the BAR relative addressing and pass <i>Offset</i> to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in Section 13.4 .
<i>Offset</i>	The offset within the selected BAR to start the I/O operation.
<i>Mask</i>	Mask used for the polling criteria. Bytes above <i>Width</i> in <i>Mask</i> are ignored. The bits in the bytes below <i>Width</i> which are zero in <i>Mask</i> are ignored when polling the I/O address.
<i>Value</i>	The comparison value used for the polling exit criteria.
<i>Delay</i>	The number of 100 ns units to poll. Note that timer available may be of poorer granularity.
<i>Result</i>	Pointer to the last value read from the memory location.

Description

This function provides a standard way to poll a PCI I/O location. A PCI I/O read operation is performed at the PCI I/O address specified by *BarIndex* and *Offset* for the width specified by *Width*. The result of this PCI I/O read operation is stored in *Result*. This PCI I/O read operation is repeated until either a timeout of *Delay* 100 ns units has expired, or (*Result & Mask*) is equal to *Value*.

This function will always perform at least one I/O access no matter how small *Delay* may be. If *Delay* is 0, then *Result* will be returned with a status of **EFI_SUCCESS** even if *Result* does not match the exit criteria. If *Delay* expires, then **EFI_TIMEOUT** is returned.

If *Width* is not **EfiPciIoWidthUint8**, **EfiPciIoWidthUint16**, **EfiPciIoWidthUint32**, or **EfiPciIoWidthUint64**, then **EFI_INVALID_PARAMETER** is returned.

The I/O operations are carried out exactly as requested. The caller is responsible satisfying any alignment and I/O width restrictions that the PCI controller on a platform might require. For example on some platforms, width requests of **EfiPciIoWidthUint64** do not work.

All the PCI read transactions generated by this function are guaranteed to be completed before this function returns.

Status Codes Returned

EFI_SUCCESS	The last data returned from the access matched the poll exit criteria.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid.
EFI_INVALID_PARAMETER	<i>Result</i> is NULL .
EFI_UNSUPPORTED	<i>BarIndex</i> not valid for this PCI controller.
EFI_UNSUPPORTED	<i>Offset</i> is not valid for the PCI BAR specified by <i>BarIndex</i> .
EFI_TIMEOUT	<i>Delay</i> expired before a match occurred.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_IO_PROTOCOL.Mem.Read() EFI_PCI_IO_PROTOCOL.Mem.Write()

Summary

Enable a PCI driver to access PCI controller registers in the PCI memory space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_MEM) (
    IN      EFI_PCI_IO_PROTOCOL      *This,
    IN      EFI_PCI_IO_PROTOCOL_WIDTH Width,
    IN      UINT8                    BarIndex,
    IN      UINT64                   Offset,
    IN      UINTN                    Count,
    IN OUT VOID                      *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI IO PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Width</i>	Signifies the width of the memory operations. Type EFI_PCI_IO_PROTOCOL_WIDTH is defined in Section 13.4 .
<i>BarIndex</i>	The BAR index of the standard PCI Configuration header to use as the base address for the memory operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value EFI_PCI_IO_PASS_THROUGH_BAR can be used to bypass the BAR relative addressing and pass <i>Offset</i> to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in Section 13.4 .
<i>Offset</i>	The offset within the selected BAR to start the memory operation.
<i>Count</i>	The number of memory operations to perform. Bytes moved is <i>Width</i> size * <i>Count</i> , starting at <i>Offset</i> .
<i>Buffer</i>	For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The **Mem.Read()**, and **Mem.Write()** functions enable a driver to access controller registers in the PCI memory space.

The I/O operations are carried out exactly as requested. The caller is responsible for any alignment and I/O width issues which the bus, device, platform, or type of I/O might require. For example on some platforms, width requests of **EfiPciIoWidthUint64** do not work.

If *Width* is **EfiPciIoWidthUint8**, **EfiPciIoWidthUint16**, **EfiPciIoWidthUint32**, or **EfiPciIoWidthUint64**, then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is **EfiPciIoWidthFifoUint8**, **EfiPciIoWidthFifoUint16**, **EfiPciIoWidthFifoUint32**, or **EfiPciIoWidthFifoUint64**, then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is **EfiPciIoWidthFillUint8**, **EfiPciIoWidthFillUint16**, **EfiPciIoWidthFillUint32**, or **EfiPciIoWidthFillUint64**, then only *Address* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns. All the PCI write transactions generated by this function will follow the write ordering and completion rules defined in the *PCI Specification*. However, if the memory-mapped I/O region being accessed by this function has the **EFI_PCI_ATTRIBUTE_MEMORY_CACHED** attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI controller.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid.
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL .
EFI_UNSUPPORTED	<i>BarIndex</i> not valid for this PCI controller.
EFI_UNSUPPORTED	The address range specified by <i>Offset</i> , <i>Width</i> , and <i>Count</i> is not valid for the PCI BAR specified by <i>BarIndex</i> .
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_IO_PROTOCOL.Io.Read() EFI_PCI_IO_PROTOCOL.Io.Write()

Summary

Enable a PCI driver to access PCI controller registers in the PCI I/O space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_MEM) (
    IN      EFI_PCI_IO_PROTOCOL      *This,
    IN      EFI_PCI_IO_PROTOCOL_WIDTH Width,
    IN      UINT8                    BarIndex,
    IN      UINT64                   Offset,
    IN      UINTN                    Count,
    IN OUT VOID                      *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_PCI_IO_PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Width</i>	Signifies the width of the memory operations. Type EFI_PCI_IO_PROTOCOL_WIDTH is defined in Section 13.4 .
<i>BarIndex</i>	The BAR index in the standard PCI Configuration header to use as the base address for the I/O operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value EFI_PCI_IO_PASS_THROUGH_BAR can be used to bypass the BAR relative addressing and pass <i>Offset</i> to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in Section 13.4 .
<i>Offset</i>	The offset within the selected BAR to start the I/O operation.
<i>Count</i>	The number of I/O operations to perform. Bytes moved is <i>Width</i> size * <i>Count</i> , starting at <i>Offset</i> .
<i>Buffer</i>	For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The `Io.Read()`, and `Io.Write()` functions enable a driver to access PCI controller registers in PCI I/O space.

The I/O operations are carried out exactly as requested. The caller is responsible for any alignment and I/O width issues which the bus, device, platform, or type of I/O might require. For example on some platforms, width requests of `EfiPciIoWidthUint64` do not work.

If *Width* is **EfiPciIoWidthUint8**, **EfiPciIoWidthUint16**, **EfiPciIoWidthUint32**, or **EfiPciIoWidthUint64**, then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is **EfiPciIoWidthFifoUint8**, **EfiPciIoWidthFifoUint16**, **EfiPciIoWidthFifoUint32**, or **EfiPciIoWidthFifoUint64**, then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is **EfiPciIoWidthFillUint8**, **EfiPciIoWidthFillUint16**, **EfiPciIoWidthFillUint32**, or **EfiPciIoWidthFillUint64**, then only *Address* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI controller.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid.
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL .
EFI_UNSUPPORTED	<i>BarIndex</i> not valid for this PCI controller.
EFI_UNSUPPORTED	The address range specified by <i>Offset</i> , <i>Width</i> , and <i>Count</i> is not valid for the PCI BAR specified by <i>BarIndex</i> .
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_IO_PROTOCOL.Pci.Read() EFI_PCI_IO_PROTOCOL.Pci.Write()

Summary

Enable a PCI driver to access PCI controller registers in PCI configuration space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_CONFIG) (
    IN      EFI_PCI_IO_PROTOCOL      *This,
    IN      EFI_PCI_IO_PROTOCOL_WIDTH Width,
    IN      UINT32                    Offset,
    IN      UINTN                     Count,
    IN OUT VOID                       *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI IO PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Width</i>	Signifies the width of the memory operations. Type EFI_PCI_IO_PROTOCOL_WIDTH is defined in Section 13.4 .
<i>Offset</i>	The offset within the PCI configuration space for the PCI controller.
<i>Count</i>	The number of PCI configuration operations to perform. Bytes moved is <i>Width</i> size * <i>Count</i> , starting at <i>Offset</i> .
<i>Buffer</i>	For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The **Pci.Read()** and **Pci.Write()** functions enable a driver to access PCI configuration registers for the PCI controller.

The PCI Configuration operations are carried out exactly as requested. The caller is responsible for any alignment and I/O width issues which the bus, device, platform, or type of I/O might require. For example on some platforms, width requests of **EfiPciIoWidthUint64** do not work.

If *Width* is **EfiPciIoWidthUint8**, **EfiPciIoWidthUint16**, **EfiPciIoWidthUint32**, or **EfiPciIoWidthUint64**, then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is **EfiPciIoWidthFifoUint8**, **EfiPciIoWidthFifoUint16**, **EfiPciIoWidthFifoUint32**, or **EfiPciIoWidthFifoUint64**, then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is **EfiPciIoWidthFillUint8**, **EfiPciIoWidthFillUint16**, **EfiPciIoWidthFillUint32**, or **EfiPciIoWidthFillUint64**, then only *Address* is

incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI controller.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid.
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL .
EFI_UNSUPPORTED	The address range specified by <i>Offset</i> , <i>Width</i> , and <i>Count</i> is not valid for the PCI configuration header of the PCI controller.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_IO_PROTOCOL.CopyMem()

Summary

Enables a PCI driver to copy one region of PCI memory space to another region of PCI memory space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_COPY_MEM) (
    IN      EFI_PCI_IO_PROTOCOL      *This,
    IN      EFI_PCI_IO_PROTOCOL_WIDTH Width,
    IN      UINT8                    DestBarIndex,
    IN      UINT64                   DestOffset,
    IN      UINT8                    SrcBarIndex,
    IN      UINT64                   SrcOffset,
    IN      UINTN                    Count
);
```

Parameters

<i>This</i>	A pointer to the EFI_PCI_IO_PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Width</i>	Signifies the width of the memory operations. Type EFI_PCI_IO_PROTOCOL_WIDTH is defined in Section 13.4 .
<i>DestBarIndex</i>	The BAR index in the standard PCI Configuration header to use as the base address for the memory operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value EFI_PCI_IO_PASS_THROUGH_BAR can be used to bypass the BAR relative addressing and pass <i>Offset</i> to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in Section 13.4 .
<i>DestOffset</i>	The destination offset within the BAR specified by <i>DestBarIndex</i> to start the memory writes for the copy operation. The caller is responsible for aligning the <i>DestOffset</i> if required.
<i>SrcBarIndex</i>	The BAR index in the standard PCI Configuration header to use as the base address for the memory operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value EFI_PCI_IO_PASS_THROUGH_BAR can be used to bypass the BAR relative addressing and pass <i>Offset</i> to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in Section 13.4 .

<i>SrcOffset</i>	The source offset within the BAR specified by <i>SrcBarIndex</i> to start the memory reads for the copy operation. The caller is responsible for aligning the <i>SrcOffset</i> if required.
<i>Count</i>	The number of memory operations to perform. Bytes moved is <i>Width</i> size * <i>Count</i> , starting at <i>DestOffset</i> and <i>SrcOffset</i> .

Description

The **CopyMem()** function enables a PCI driver to copy one region of PCI memory space to another region of PCI memory space on a PCI controller. This is especially useful for video scroll operations on a memory mapped video buffer.

The memory operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and memory width restrictions that a PCI controller on a platform might require. For example on some platforms, width requests of **EfiPciIoWidthUint64** do not work.

If *Width* is **EfiPciIoWidthUint8**, **EfiPciIoWidthUint16**, **EfiPciIoWidthUint32**, or **EfiPciIoWidthUint64**, then *Count* read/write transactions are performed to move the contents of the *SrcOffset* buffer to the *DestOffset* buffer. The implementation must be reentrant, and it must handle overlapping *SrcOffset* and *DestOffset* buffers. This means that the implementation of **CopyMem()** must choose the correct direction of the copy operation based on the type of overlap that exists between the *SrcOffset* and *DestOffset* buffers. If either the *SrcOffset* buffer or the *DestOffset* buffer crosses the top of the processor’s address space, then the result of the copy operation is unpredictable.

The contents of the *DestOffset* buffer on exit from this service must match the contents of the *SrcOffset* buffer on entry to this service. Due to potential overlaps, the contents of the *SrcOffset* buffer may be modified by this service. The following rules can be used to guarantee the correct behavior:

- If $DestOffset > SrcOffset$ and $DestOffset < (SrcOffset + Width\ size * Count)$, then the data should be copied from the *SrcOffset* buffer to the *DestOffset* buffer starting from the end of buffers and working toward the beginning of the buffers.
- Otherwise, the data should be copied from the *SrcOffset* buffer to the *DestOffset* buffer starting from the beginning of the buffers and working toward the end of the buffers.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns. All the PCI write transactions generated by this function will follow the write ordering and completion rules defined in the *PCI Specification*. However, if the memory-mapped I/O region being accessed by this function has the **EFI_PCI_ATTRIBUTE_MEMORY_CACHED** attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The data was EFI copied from one memory region to another memory region.
EFI_INVALID_PARAMETER	<i>Width</i> is invalid.
EFI_UNSUPPORTED	<i>DestBarIndex</i> not valid for this PCI controller.

EFI_UNSUPPORTED	<i>SrcBarIndex</i> not valid for this PCI controller.
EFI_UNSUPPORTED	The address range specified by <i>DestOffset</i> , <i>Width</i> , and <i>Count</i> is not valid for the PCI BAR specified by <i>DestBarIndex</i> .
EFI_UNSUPPORTED	The address range specified by <i>SrcOffset</i> , <i>Width</i> , and <i>Count</i> is not valid for the PCI BAR specified by <i>SrcBarIndex</i> .
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_IO_PROTOCOL.Map()

Summary

Provides the PCI controller–specific addresses needed to access system memory.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_MAP) (
    IN      EFI_PCI_IO_PROTOCOL      *This,
    IN      EFI_PCI_IO_PROTOCOL_OPERATION Operation,
    IN      VOID                      *HostAddress,
    IN OUT  UINTN                    *NumberOfBytes,
    OUT     EFI_PHYSICAL_ADDRESS     *DeviceAddress,
    OUT     VOID                      **Mapping
);
```

Parameters

<i>This</i>	A pointer to the EFI_PCI_IO_PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Operation</i>	Indicates if the bus master is going to read or write to system memory. Type EFI_PCI_IO_PROTOCOL_OPERATION is defined in Section 13.4 .
<i>HostAddress</i>	The system memory address to map to the PCI controller.
<i>NumberOfBytes</i>	On input the number of bytes to map. On output the number of bytes that were mapped.
<i>DeviceAddress</i>	The resulting map address for the bus master PCI controller to use to access the hosts <i>HostAddress</i> . Type EFI_PHYSICAL_ADDRESS is defined in Section 6.2 . This address cannot be used by the processor to access the contents of the buffer specified by <i>HostAddress</i> .
<i>Mapping</i>	A resulting value to pass to Unmap() .

Description

The [Map\(\)](#) function provides the PCI controller–specific addresses needed to access system memory. This function is used to map system memory for PCI bus master DMA accesses.

All PCI bus master accesses must be performed through their mapped addresses and such mappings must be freed with [Unmap\(\)](#) when complete. If the bus master access is a single read or write data transfer, then [EfiPciIoOperationBusMasterRead](#) or [EfiPciIoOperationBusMasterWrite](#) is used and the range is unmapped to complete the operation. If performing an [EfiPciIoOperationBusMasterRead](#) operation, all the data must be present in system memory before the [Map\(\)](#) is performed. Similarly, if performing an [EfiPciIoOperationBusMasterWrite](#), the data cannot be properly accessed in system memory until [Unmap\(\)](#) is performed.

Bus master operations that require both read and write access or require multiple host device interactions within the same mapped region must use **EfiPciIoOperation-BusMasterCommonBuffer**. However, only memory allocated via the [AllocateBuffer\(\)](#) interface can be mapped for this operation type.

In all mapping requests the resulting *NumberOfBytes* actually mapped may be less than the requested amount. In this case, the DMA operation will have to be broken up into smaller chunks. The **Map()** function will map as much of the DMA operation as it can at one time. The caller may have to loop on **Map()** and **Unmap()** in order to complete a large DMA transfer.

Status Codes Returned

EFI_SUCCESS	The range was mapped for the returned <i>NumberOfBytes</i> .
EFI_INVALID_PARAMETER	<i>Operation</i> is invalid.
EFI_INVALID_PARAMETER	<i>HostAddress</i> is NULL .
EFI_INVALID_PARAMETER	<i>NumberOfBytes</i> is NULL .
EFI_INVALID_PARAMETER	<i>DeviceAddress</i> is NULL .
EFI_INVALID_PARAMETER	<i>Mapping</i> is NULL .
EFI_UNSUPPORTED	The <i>HostAddress</i> cannot be mapped as a common buffer.
EFI_DEVICE_ERROR	The system hardware could not map the requested address.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_PCI_IO_PROTOCOL.Unmap()

Summary

Completes the [Map \(\)](#) operation and releases any corresponding resources.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_UNMAP) (
    IN  EFI_PCI_IO_PROTOCOL  *This,
    IN  VOID                  *Mapping
);
```

Parameters

This

A pointer to the [EFI PCI IO PROTOCOL](#) instance. Type [EFI_PCI_IO_PROTOCOL](#) is defined in [Section 13.4](#).

Mapping

The mapping value returned from [Map \(\)](#).

Description

The [Unmap \(\)](#) function completes the [Map \(\)](#) operation and releases any corresponding resources. If the operation was an [EfiPciIoOperationBusMasterWrite](#), the data is committed to the target system memory. Any resources used for the mapping are freed.

Status Codes Returned

EFI_SUCCESS	The range was unmapped.
EFI_DEVICE_ERROR	The data was not committed to the target system memory.

EFI_PCI_IO_PROTOCOL.AllocateBuffer()

Summary

Allocates pages that are suitable for an **EfiPciIoOperationBusMasterCommonBuffer** mapping.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_ALLOCATE_BUFFER) (
    IN      EFI_PCI_IO_PROTOCOL  *This,
    IN      EFI_ALLOCATE_TYPE    Type,
    IN      EFI_MEMORY_TYPE      MemoryType,
    IN      UINTN                Pages,
    OUT     VOID                 **HostAddress,
    IN      UINT64               Attributes
);
```

Parameters

<i>This</i>	A pointer to the EFI_PCI_IO_PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Type</i>	This parameter is not used and must be ignored.
<i>MemoryType</i>	The type of memory to allocate, EfiBootServicesData or EfiRuntimeServicesData . Type EFI_MEMORY_TYPE is defined in Chapter Section 6.2 .
<i>Pages</i>	The number of pages to allocate.
<i>HostAddress</i>	A pointer to store the base system memory address of the allocated range.
<i>Attributes</i>	The requested bit mask of attributes for the allocated range. Only the attributes EFI_PCI_ATTRIBUTE_MEMORY_WRITE_COMBINE , and EFI_PCI_ATTRIBUTE_MEMORY_CACHED may be used with this function. If any other bits are set, then EFI_UNSUPPORTED is returned. This function may choose to ignore this bit mask. The EFI_PCI_ATTRIBUTE_MEMORY_WRITE_COMBINE , and EFI_PCI_ATTRIBUTE_MEMORY_CACHED attributes provide a hint to the implementation that may improve the performance of the calling driver. The implementation may choose any default for the memory attributes including write combining, cached, both, or neither as long as the allocated buffer can be seen equally by both the processor and the PCI bus master.

Description

The **AllocateBuffer()** function allocates pages that are suitable for an **EfiPciIoOperationBusMasterCommonBuffer** mapping. This means that the buffer allocated by this function must support simultaneous access by both the processor and a PCI Bus

Master. The device address that the PCI Bus Master uses to access the buffer can be retrieved with a call to [Map\(\)](#).

If the current attributes of the PCI controller has the

EFI_PCI_IO_ATTRIBUTE_DUAL_ADDRESS_CYCLE bit set, then when the buffer allocated by this function is mapped with a call to **Map()**, the device address that is returned by **Map()** must be within the 64-bit device address space of the PCI Bus Master. The attributes for a PCI controller can be managed by calling [Attributes\(\)](#).

If the current attributes for the PCI controller has the

EFI_PCI_IO_ATTRIBUTE_DUAL_ADDRESS_CYCLE bit clear, then when the buffer allocated by this function is mapped with a call to **Map()**, the device address that is returned by **Map()** must be within the 32-bit device address space of the PCI Bus Master. The attributes for a PCI controller can be managed by calling **Attributes()**.

If the memory allocation specified by *MemoryType* and *Pages* cannot be satisfied, then **EFI_OUT_OF_RESOURCES** is returned.

Status Codes Returned

EFI_SUCCESS	The requested memory pages were allocated.
EFI_INVALID_PARAMETER	<i>MemoryType</i> is invalid.
EFI_INVALID_PARAMETER	<i>HostAddress</i> is NULL .
EFI_UNSUPPORTED	<i>Attributes</i> is unsupported. The only legal attribute bits are MEMORY_WRITE_COMBINE and MEMORY_CACHED .
EFI_OUT_OF_RESOURCES	The memory pages could not be allocated.

EFI_PCI_IO_PROTOCOL.FreeBuffer()

Summary

Frees memory that was allocated with [AllocateBuffer\(\)](#).

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_FREE_BUFFER) (
    IN  EFI_PCI_IO_PROTOCOL  *This,
    IN  UINTN                 Pages,
    IN  VOID                  *HostAddress
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI IO PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Pages</i>	The number of pages to free.
<i>HostAddress</i>	The base system memory address of the allocated range.

Description

The **FreeBuffer()** function frees memory that was allocated with **AllocateBuffer()**.

Status Codes Returned

EFI_SUCCESS	The requested memory pages were freed.
EFI_INVALID_PARAMETER	The memory range specified by <i>HostAddress</i> and <i>Pages</i> was not allocated with AllocateBuffer() .

EFI_PCI_IO_PROTOCOL.Flush()

Summary

Flushes all PCI posted write transactions from a PCI host bridge to system memory.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_PCI_IO_PROTOCOL_FLUSH) (
    IN EFI_PCI_IO_PROTOCOL *This
);
```

Parameters

This A pointer to the [EFI_PCI_IO_PROTOCOL](#) instance. Type [EFI_PCI_IO_PROTOCOL](#) is defined in [Section 13.4](#).

Description

The **Flush()** function flushes any PCI posted write transactions from a PCI host bridge to system memory. Posted write transactions are generated by PCI bus masters when they perform write transactions to target addresses in system memory.

This function does not flush posted write transactions from any PCI bridges. A PCI controller specific action must be taken to guarantee that the posted write transactions have been flushed from the PCI controller and from all the PCI bridges into the PCI host bridge. This is typically done with a PCI read transaction from the PCI controller prior to calling **Flush()**.

If the PCI controller specific action required to flush the PCI posted write transactions has been performed, and this function returns **EFI_SUCCESS**, then the PCI bus master’s view and the processor’s view of system memory are guaranteed to be coherent. If the PCI posted write transactions cannot be flushed from the PCI host bridge, then the PCI bus master and processor are not guaranteed to have a coherent view of system memory, and **EFI_DEVICE_ERROR** is returned.

Status Codes Returned

EFI_SUCCESS	The PCI posted write transactions were flushed from the PCI host bridge to system memory.
EFI_DEVICE_ERROR	The PCI posted write transactions were not flushed from the PCI host bridge due to a hardware error.

EFI_PCI_IO_PROTOCOL.GetLocation()

Summary

Retrieves this PCI controller’s current PCI bus number, device number, and function number.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_GET_LOCATION) (
    IN  EFI_PCI_IO_PROTOCOL  *This,
    OUT UINTN                 *SegmentNumber,
    OUT UINTN                 *BusNumber,
    OUT UINTN                 *DeviceNumber,
    OUT UINTN                 *FunctionNumber
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI IO PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>SegmentNumber</i>	The PCI controller’s current PCI segment number.
<i>BusNumber</i>	The PCI controller’s current PCI bus number.
<i>DeviceNumber</i>	The PCI controller’s current PCI device number.
<i>FunctionNumber</i>	The PCI controller’s current PCI function number.

Description

The **GetLocation()** function retrieves a PCI controller’s current location on a PCI Host Bridge. This is specified by a PCI segment number, PCI bus number, PCI device number, and PCI function number. These values can be used with the PCI Root Bridge I/O Protocol to perform PCI configuration cycles on the PCI controller, or any of its peer PCI controller’s on the same PCI Host Bridge.

Status Codes Returned

EFI_SUCCESS	The PCI controller location was returned.
EFI_INVALID_PARAMETER	SegmentNumber is NULL .
EFI_INVALID_PARAMETER	BusNumber is NULL .
EFI_INVALID_PARAMETER	DeviceNumber is NULL .
EFI_INVALID_PARAMETER	FunctionNumber is NULL .

EFI_PCI_IO_PROTOCOL.Attributes()

Summary

Performs an operation on the attributes that this PCI controller supports. The operations include getting the set of supported attributes, retrieving the current attributes, setting the current attributes, enabling attributes, and disabling attributes.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_ATTRIBUTES) (
    IN EFI_PCI_IO_PROTOCOL           *This,
    IN EFI_PCI_IO_PROTOCOL_ATTRIBUTE_OPERATION Operation,
    IN UINT64                       Attributes,
    OUT UINT64                       *Result OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_PCI_IO_PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Operation</i>	The operation to perform on the attributes for this PCI controller. Type EFI_PCI_IO_PROTOCOL_ATTRIBUTE_OPERATION is defined in “Related Definitions” below.
<i>Attributes</i>	The mask of attributes that are used for Set , Enable , and Disable operations. The available attributes are listed in Section 13.4 .
<i>Result</i>	A pointer to the result mask of attributes that are returned for the Get and Supported operations. This is an optional parameter that may be NULL for the Set , Enable , and Disable operations. The available attributes are listed in Section 13.4 .

Related Definitions

```

//*****
// EFI_PCI_IO_PROTOCOL_ATTRIBUTE_OPERATION
//*****
typedef enum {
    EfiPciIoAttributeOperationGet,
    EfiPciIoAttributeOperationSet,
    EfiPciIoAttributeOperationEnable,
    EfiPciIoAttributeOperationDisable,
    EfiPciIoAttributeOperationSupported,
    EfiPciIoAttributeOperationMaximum
} EFI_PCI_IO_PROTOCOL_ATTRIBUTE_OPERATION;
```

EfiPciIoAttributeOperationGet

Retrieve the PCI controller's current attributes, and return them in *Result*. If *Result* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. For this operation, *Attributes* is ignored.

EfiPciIoAttributeOperationSet

Set the PCI controller's current attributes to *Attributes*. If a bit is set in *Attributes* that is not supported by this PCI controller or one of its parent bridges, then **EFI_UNSUPPORTED** is returned. For this operation, *Result* is an optional parameter that may be **NULL**.

EfiPciIoAttributeOperationEnable

Enable the attributes specified by the bits that are set in *Attributes* for this PCI controller. Bits in *Attributes* that are clear are ignored. If a bit is set in *Attributes* that is not supported by this PCI controller or one of its parent bridges, then **EFI_UNSUPPORTED** is returned. For this operation, *Result* is an optional parameter that may be **NULL**.

EfiPciIoAttributeOperationDisable

Disable the attributes specified by the bits that are set in *Attributes* for this PCI controller. Bits in *Attributes* that are clear are ignored. If a bit is set in *Attributes* that is not supported by this PCI controller or one of its parent bridges, then **EFI_UNSUPPORTED** is returned. For this operation, *Result* is an optional parameter that may be **NULL**.

EfiPciIoAttributeOperationSupported

Retrieve the PCI controller's supported attributes, and return them in *Result*. If *Result* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. For this operation, *Attributes* is ignored.

Description

The **Attributes ()** function performs an operation on the attributes associated with this PCI controller. If *Operation* is greater than or equal to the maximum operation value, then **EFI_INVALID_PARAMETER** is returned. If *Operation* is **Get** or **Supported**, and *Result* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If *Operation* is **Set**, **Enable**, or **Disable** for an attribute that is not supported by the PCI controller, then **EFI_UNSUPPORTED** is returned. Otherwise, the operation is performed as described in “Related Definitions” and **EFI_SUCCESS** is returned. It is possible for this function to return **EFI_UNSUPPORTED** even if the PCI controller supports the attribute. This can occur when the PCI root bridge does not support the attribute. For example, if VGA I/O and VGA Memory transactions cannot be forwarded onto PCI root bridge #2, then a request by a PCI VGA driver to enable the **VGA_IO** and **VGA_MEMORY** bits will fail even though a PCI VGA controller behind PCI root bridge #2 is able to decode these transactions.

This function will also return **EFI_UNSUPPORTED** if more than one PCI controller on the same PCI root bridge has already successfully requested one of the ISA addressing attributes. For example, if one PCI VGA controller had already requested the **VGA_IO** and **VGA_MEMORY** attributes, then a second PCI VGA controller on the same root bridge cannot succeed in requesting those same attributes. This restriction applies to the ISA-, VGA-, and IDE-related attributes.

Status Codes Returned

EFI_SUCCESS	The operation on the PCI controller's attributes was completed. If the operation was Get or Supported , then the attribute mask is returned in <i>Result</i> .
EFI_INVALID_PARAMETER	<i>Operation</i> is greater than or equal to EfiPciIoAttributeOperationMaximum .
EFI_INVALID_PARAMETER	<i>Operation</i> is Get and <i>Result</i> is NULL .
EFI_INVALID_PARAMETER	<i>Operation</i> is Supported and <i>Result</i> is NULL .
EFI_UNSUPPORTED	<i>Operation</i> is Set , and one or more of the bits set in <i>Attributes</i> are not supported by this PCI controller or one of its parent bridges.
EFI_UNSUPPORTED	<i>Operation</i> is Enable , and one or more of the bits set in <i>Attributes</i> are not supported by this PCI controller or one of its parent bridges.
EFI_UNSUPPORTED	<i>Operation</i> is Disable , and one or more of the bits set in <i>Attributes</i> are not supported by this PCI controller or one of its parent bridges.

EFI_PCI_IO_PROTOCOL.GetBarAttributes()

Summary

Gets the attributes that this PCI controller supports setting on a BAR using [SetBarAttributes\(\)](#), and retrieves the list of resource descriptors for a BAR.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_GET_BAR_ATTRIBUTES) (
    IN  EFI_PCI_IO_PROTOCOL  *This,
    IN  UINT8                BarIndex,
    OUT UINT64               *Supports    OPTIONAL,
    OUT VOID                 **Resources  OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI IO PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>BarIndex</i>	The BAR index of the standard PCI Configuration header to use as the base address for resource range. The legal range for this field is 0..5.
<i>Supports</i>	A pointer to the mask of attributes that this PCI controller supports setting for this BAR with SetBarAttributes() . The list of attributes is listed in Section 13.4 . This is an optional parameter that may be NULL .
<i>Resources</i>	A pointer to the ACPI 2.0 resource descriptors that describe the current configuration of this BAR of the PCI controller. This buffer is allocated for the caller with the Boot Service EFI_BOOT_SERVICES.AllocatePool() . It is the caller's responsibility to free the buffer with the Boot Service EFI_BOOT_SERVICES.FreePool() . See "Related Definitions" below for the ACPI 2.0 resource descriptors that may be used. This is an optional parameter that may be NULL .

Related Definitions

There are only two resource descriptor types from the *ACPI Specification* that may be used to describe the current resources allocated to BAR of a PCI Controller. These are the QWORD Address Space Descriptor (ACPI 2.0 Section 6.4.3.5.1), and the End Tag (ACPI 2.0 Section 6.4.2.8). The QWORD Address Space Descriptor can describe memory, I/O, and bus number ranges for dynamic or fixed resources. The configuration of a BAR of a PCI Controller is described with one or more QWORD Address Space Descriptors followed by an End Tag. [Table 120](#) and [Table 121](#) contain these two descriptor types. Please see the *ACPI Specification* for details on the field values. The *ACPI Specification* does not define how to use the Address Translation Offset for non-bridge devices. The UEFI Specification is extending the definition of Address Translation Offset to support systems that have different mapping for HostAddress and DeviceAddress. The definition of the

Address Space Granularity field in the ACPI 2.0 QWORD Address Space Descriptor differs from the *ACPI 2.0 Specification* and the definition in [Table 120](#) is that one that must be used.

Table 120. ACPI 2.0 QWORD Address Space Descriptor

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x8A	QWORD Address Space Descriptor
0x01	0x02	0x2B	Length of this descriptor in bytes not including the first two fields
0x03	0x01		Resource Type 0 – Memory Range 1 – I/O Range 2 – Bus Number Range
0x04	0x01		General Flags
0x05	0x01		Type Specific Flags
0x06	0x08		Address Space Granularity.
0x0E	0x08		Address Range Minimum. Starting address of BAR.
0x16	0x08		Address Range Maximum. Ending address of BAR.
0x1E	0x08		Address Translation Offset. Offset to apply to the Starting address of a BAR to convert it to a PCI address. This value is zero unless the HostAddress and DeviceAddress for the BAR are different. Used to differentiate between a 32-bit memory request and a 64-bit memory request. For a 32-bit memory request, this field should be set to 32. For a 64-bit memory request, this field should be set to 64.
0x26	0x08		Address Length

Table 121. ACPI 2.0 End Tag

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x79	End Tag
0x01	0x01	0x00	Checksum. If 0, then checksum is assumed to be valid.

Description

The **GetBarAttributes ()** function returns in *Supports* the mask of attributes that the PCI controller supports setting for the BAR specified by *BarIndex*. It also returns in *Resources* a list of ACPI 2.0 resource descriptors for the BAR specified by *BarIndex*. Both *Supports* and *Resources* are optional parameters. If both *Supports* and *Resources* are **NULL**, then **EFI_INVALID_PARAMETER** is returned. It is the caller’s responsibility to free *Resources* with the Boot Service [EFI_BOOT_SERVICES.FreePool \(\)](#) when the caller is done with the contents of *Resources*. If there are not enough resources to allocate *Resources*, then **EFI_OUT_OF_RESOURCES** is returned.

If a bit is set in *Supports*, then the PCI controller supports this attribute type for the BAR specified by *BarIndex*, and a call can be made to [SetBarAttributes\(\)](#) using that attribute type.

Status Codes Returned

EFI_SUCCESS	If <i>Supports</i> is not NULL , then the attributes that the PCI controller supports are returned in <i>Supports</i> . If <i>Resources</i> is not NULL , then the ACPI 2.0 resource descriptors that the PCI controller is currently using are returned in <i>Resources</i> .
EFI_OUT_OF_RESOURCES	There are not enough resources available to allocate <i>Resources</i> .
EFI_UNSUPPORTED	<i>BarIndex</i> not valid for this PCI controller.
EFI_INVALID_PARAMETER	Both <i>Supports</i> and <i>Attributes</i> are NULL .

EFI_PCI_IO_PROTOCOL.SetBarAttributes()

Summary

Sets the attributes for a range of a BAR on a PCI controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_SET_BAR_ATTRIBUTES) (
    IN      EFI_PCI_IO_PROTOCOL  *This,
    IN      UINT64               Attributes,
    IN      UINT8                BarIndex,
    IN OUT  UINT64               *Offset,
    IN OUT  UINT64               *Length
);
```

Parameters

<i>This</i>	A pointer to the EFI PCI IO PROTOCOL instance. Type EFI_PCI_IO_PROTOCOL is defined in Section 13.4 .
<i>Attributes</i>	The mask of attributes to set for the resource range specified by <i>BarIndex</i> , <i>Offset</i> , and <i>Length</i> .
<i>BarIndex</i>	The BAR index of the standard PCI Configuration header to use as the base address for the resource range. The legal range for this field is 0..5.
<i>Offset</i>	A pointer to the BAR relative base address of the resource range to be modified by the attributes specified by <i>Attributes</i> . On return, <i>*Offset</i> will be set to the actual base address of the resource range. Not all resources can be set to a byte boundary, so the actual base address may differ from the one passed in by the caller.
<i>Length</i>	A pointer to the length of the resource range to be modified by the attributes specified by <i>Attributes</i> . On return, <i>*Length</i> will be set to the actual length of the resource range. Not all resources can be set to a byte boundary, so the actual length may differ from the one passed in by the caller.

Description

The **SetBarAttributes()** function sets the attributes specified in *Attributes* for the PCI controller on the resource range specified by *BarIndex*, *Offset*, and *Length*. Since the granularity of setting these attributes may vary from resource type to resource type, and from platform to platform, the actual resource range and the one passed in by the caller may differ. As a result, this function may set the attributes specified by *Attributes* on a larger resource range than the caller requested. The actual range is returned in *Offset* and *Length*. The caller is responsible for verifying that the actual range for which the attributes were set is acceptable.

If the attributes are set on the PCI controller, then the actual resource range is returned in *Offset* and *Length*, and **EFI_SUCCESS** is returned. Many of the attribute types also require that the state

of the PCI Host Bus Controller and the state of any PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller to be modified. This function will only return **EFI_SUCCESS** if all of these state changes are made. The PCI Controller may support a combination of attributes, but unless the PCI Host Bus Controller and the PCI to PCI bridges also support that same combination of attributes, then this call will return an error.

If the attributes specified by *Attributes*, or the resource range specified by *BarIndex*, *Offset*, and *Length* are not supported by the PCI controller, then **EFI_UNSUPPORTED** is returned. The set of supported attributes for the PCI controller can be found by calling [GetBarAttributes\(\)](#).

If either *Offset* or *Length* is **NULL** then **EFI_INVALID_PARAMETER** is returned.

If there are not enough resources available to set the attributes, then **EFI_OUT_OF_RESOURCES** is returned.

Status Codes Returned

EFI_SUCCESS	The set of attributes specified by <i>Attributes</i> for the resource range specified by <i>BarIndex</i> , <i>Offset</i> , and <i>Length</i> were set on the PCI controller, and the actual resource range is returned in <i>Offset</i> and <i>Length</i> .
EFI_UNSUPPORTED	The set of attributes specified by <i>Attributes</i> is not supported by the PCI controller for the resource range specified by <i>BarIndex</i> , <i>Offset</i> , and <i>Length</i> .
EFI_INVALID_PARAMETER	<i>Offset</i> is NULL .
EFI_INVALID_PARAMETER	<i>Length</i> is NULL .
EFI_OUT_OF_RESOURCES	There are not enough resources to set the attributes on the resource range specified by <i>BarIndex</i> , <i>Offset</i> , and <i>Length</i> .

13.4.1 PCI Device Paths

An [EFI PCI IO PROTOCOL](#) must be installed on a handle for its services to be available to PCI device drivers. In addition to the [EFI PCI IO PROTOCOL](#), an [EFI DEVICE PATH PROTOCOL](#) must also be installed on the same handle. See Chapter [Section 9](#) for a detailed description of the [EFI_DEVICE_PATH_PROTOCOL](#).

Typically, an ACPI Device Path Node is used to describe a PCI Root Bridge. Depending on the bus hierarchy in the system, additional device path nodes may precede this ACPI Device Path Node. A PCI device path is described with PCI Device Path Nodes. There will be one PCI Device Path node for the PCI controller itself, and one PCI Device Path Node for each PCI to PCI Bridge that is between the PCI controller and the PCI Root Bridge.

[Table 122](#) shows an example device path for a PCI controller that is located at PCI device number 0x07 and PCI function 0x00, and is directly attached to a PCI root bridge. This device path consists of an ACPI Device Path Node, a PCI Device Path Node, and a Device Path End Structure. The `_HID` and `_UID` must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

ACPI (PNP0A03, 0) / PCI (7, 0).

Table 122. PCI Device 7, Function 0 on PCI Root Bridge 0

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x00	PCI Function
0x11	0x01	0x07	PCI Device
0x12	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x13	0x01	0xFF	Sub type – End of Entire Device Path
0x14	0x02	0x04	Length – 0x04 bytes

[Table 123](#) shows an example device path for a PCI controller that is located behind a PCI to PCI bridge at PCI device number 0x07 and PCI function 0x00. The PCI to PCI bridge is directly attached to a PCI root bridge, and it is at PCI device number 0x05 and PCI function 0x00. This device path consists of an ACPI Device Path Node, two PCI Device Path Nodes, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

ACPI (PNP0A03, 0) / PCI (5, 0) / PCI (7, 0) .

Table 123. PCI Device 7, Function 0 behind PCI to PCI bridge

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x00	PCI Function
0x11	0x01	0x05	PCI Device

Byte Offset	Byte Length	Data	Description
0x12	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x13	0x01	0x01	Sub type – PCI
0x14	0x02	0x06	Length – 0x06 bytes
0x16	0x01	0x00	PCI Function
0x17	0x01	0x07	PCI Device
0x18	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x19	0x01	0xFF	Sub type – End of Entire Device Path
0x1A	0x02	0x04	Length – 0x04 bytes

13.4.2 PCI Option ROMs

EFI takes advantage of both the *PCI Firmware Specification* and the *PE/COFF Specification* to store EFI images in a PCI Option ROM. There are several rules that must be followed when constructing a PCI Option ROM:

- A PCI Option ROM can be no larger than 16 MiB.
- A PCI Option ROM may contain one or more images.
- Each image must be on a 512-byte boundary.
- Each image must be an even multiple of 512 bytes in length. This means that images that are not an even multiple of 512 bytes in length must be padded to the next 512-byte boundary.
- Legacy Option ROM images begin with a Standard PCI Expansion ROM Header ([Table 124](#)).
- EFI Option ROM images begin with an EFI PCI Expansion ROM Header ([Table 128](#)).
- Each image must contain a PCIR data structure in the first 64 KiB of the image.
- The image data for an EFI Option ROM image must begin in the first 64 KiB of the image.
- The image data for an EFI Option ROM image must be a PE/COFF image or a compressed PE/COFF image following the UEFI Compression Algorithm, and referencing [Appendix H](#) for the Compression Source Code.
- The PCIR data structure must begin on a 4-byte boundary.
- If the PCI Option ROM contains a Legacy Option ROM image, it must be the first image.
- The images are placed in the PCI Option ROM in order from highest to lowest priority. This priority is used to build the ordered list of Driver Image Handles that are produced by the Bus Specific Driver Override Protocol for a PCI Controller.
- When PCI device provides an EFI option ROM that is signed in accordance with Chapter 27, use of UEFI Compression Algorithm storage option is preferred. When performing signature validation upon compressed driver, the size returned by `EFI_DECOMPRESS_PROTOCOL.GetInfo()` will be used as driver size and input to signature validation process. Thus any post-driver padding required to reach exact multiple of 512 bytes per [Figure 45](#) is ignored by signature validation.
- When PCI device provides an EFI option ROM that is signed in accordance with Chapter 27 and stored uncompressed, the end of the driver for signature validation will be the assumed to be the

512-byte boundary indicated by the ‘Initialization Size’ value in the EFI PCI Expansion ROM Header (see [Table 126](#)). As the signed driver may not exactly fill the indicated ‘Initialization Size’, it is recommended that the value ‘Offset to EFI Image’ (also [Table 126](#)) be adjusted to ensure the last byte of the signed, uncompressed driver, coincides with the end of the ROM as indicated by ‘Initialization Size’. And any required padding bytes are to be inserted ahead of the signed uncompressed driver image.

There are several options available when building a PCI option ROM for a PCI adapter. A PCI Option ROM can choose to support only a legacy PC-AT platform, only an EFI compliant platform, or both. This flexibility allows a migration path from adapters that support only legacy PC-AT platforms, to adapters that support both PC-AT platforms and EFI compliant platforms, to adapters that support only EFI compliant platforms. The following is a list of the image combinations that may be placed in a PCI option ROM. This is not an exhaustive list. Instead, it provides what will likely be the most common PCI option ROM layouts. EFI complaint system firmware must work with all of these PCI option ROM layouts, plus any other layouts that are possible within the *PCI Firmware Specification*. The format of a Legacy Option ROM image is defined in the *PCI Firmware Specification*.

- Legacy Option ROM image
- Legacy Option ROM image + IA-32 EFI driver
- Legacy Option ROM image + Itanium Processor Family EFI driver
- Legacy Option ROM image + IA-32 EFI driver + Itanium Processor Family EFI driver
- Legacy Option ROM image + IA-32 EFI driver + x64 EFI driver
- Legacy Option ROM image + EBC Driver
- IA-32 UEFI driver
- Itanium Processor Family EFI driver
- IA-32 UEFI driver + Itanium Processor Family EFI driver
- EBC Driver

In addition to combinations of UEFI drivers with different processor binding, it is also possible to include multiple drivers of different function but the same processor binding. When processing option ROM contents, all drivers of appropriate processor binding type must be loaded and added to ordered list of drivers previously mentioned.

It is also possible to place a application written to this specification in a PCI Option ROM. However, the PCI Bus Driver will ignore these images. The exact mechanism by which applications can be loaded and executed from a PCI Option ROM is outside the scope of this document.

Table 124. Standard PCI Expansion ROM Header (Example from PCI Firmware Specification 3.0)

Offset	Byte Length	Value	Description
0x00	1	0x55	ROM Signature, byte 1
0x01	1	0xAA	ROM Signature, byte 2
0x02-0x17	22	XX	Reserved per processor architecture unique data
0x18-0x19	2	XX	Pointer to PCIR Data Structure

Table 125. PCI Expansion ROM Code Types (Example from PCI Firmware Specification 3.0)

Code Type	Description
0x00	IA-32, PC-AT compatible
0x01	Open Firmware standard for PCI
0x02	Hewlett-Packard PA RISC
0x03	EFI Image
0x04-0xFF	Reserved

Table 126. EFI PCI Expansion ROM Header

Offset	Byte Length	Value	Description
0x00	1	0x55	ROM Signature, byte 1
0x01	1	0xAA	ROM Signature, byte 2
0x02	2	XXXX	Initialization Size – size of this image in units of 512 bytes. The size includes this header.
0x04	4	0x0EF1	Signature from EFI image header
0x08	2	XX	Subsystem value for EFI image header
0x0a	2	XX	Machine type from EFI image header
0x0c	2	XX	Compression type 0x0000 - The image is uncompressed 0x0001 - The image is compressed. See the UEFI Compression Algorithm and Appendix H . 0x0002 - 0xFFFF - Reserved
0x0e	8	0x00	Reserved
0x16	2	XX	Offset to EFI Image
0x18	2	XX	Offset to PCIR Data Structure

13.4.2.1 PCI Bus Driver Responsibilities

A PCI Bus Driver must scan a PCI Option ROM for PCI Device Drivers. If a PCI Option ROM is found during PCI Enumeration, then a copy of the PCI Option ROM is placed in a memory buffer. The PCI Bus Driver will use the memory copy of the PCI Option ROM to search for UEFI drivers after PCI Enumeration. The PCI Bus Driver will search the list of images in a PCI Option ROM for the ones that have a Code Type of 0x03 in the PCIR Data Structure, and a Signature of 0xEF1 in the EFI PCI Expansion ROM Header. Then, it will examine the Subsystem Type of the EFI PCI Expansion ROM Header. If the Subsystem Type is

IMAGE_SUBSYSTEM_EFI_BOOT_SERVICE_DRIVER(11) or

IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER(12), then the PCI Bus Driver can load the PCI Device Driver from the PCI Option ROM. The Offset to EFI Image Header field of the EFI PCI Expansion ROM Header is used to get a pointer to the beginning of the PE/COFF image in the PCI Option ROM. The PE/COFF image may have been compressed using the UEFI Compression Algorithm. If it has been compressed, then the PCI Bus Driver must decompress the driver to a memory buffer. The Boot Service [EFI_BOOT_SERVICES.LoadImage\(\)](#) can then be used to load the driver. All UEFI driver images discovered in the PCI Option ROM and meeting these

requirements must be processed and loaded via **LoadImage ()**. If the platform does not support the Machine Type of the driver, then **LoadImage ()** may fail.

It is the PCI Bus Driver's responsibility to verify that the Expansion ROM Header and PCIR Data Structure are valid. It is the responsibility of the Boot Service **LoadImage ()** to verify that the PE/COFF image is valid. The Boot Service **LoadImage ()** may fail for several reasons including a corrupt PE/COFF image or an unsupported Machine Type.

If a PCI Option ROM contains one or more UEFI images, then the PCI Bus Driver must install an instance of the **EFI_LOAD_FILE2_PROTOCOL** on the PCI controller handle. Then, when the PCI Bus Driver loads a PE/COFF image from a PCI Option ROM using the Boot Service **LoadImage ()**, the PCI Bus Driver must provide the device path of the image being loaded. The device path of an image loaded from a PCI Option ROM must be the device path to the PCI Controller to which the PCI Option ROM is attached followed by a Relative Offset Range node. The Starting Offset field of the Relative Offset Range node must be the byte offset from the beginning of the PCI Option ROM to the beginning of the EFI Option ROM image, and the Ending Offset field of the Relative Offset Range node must be the byte offset from the beginning of the PCI Option ROM to the end of the EFI Option ROM image. The table below shows an example device path for an EFI driver loaded from a PCI Option ROM. The EFI Driver starts at offset 0x8000 into the PCI Option ROM and is 0x2000 bytes long. The shorthand notation for this device path is:

PciRoot (0) / PCI (5, 0) / PCI (7, 0) / Offset (0x8000, 0x9FFF)

Table 127. Device Path for an EFI Driver loaded from PCI Option ROM

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x00	PCI Function
0x11	0x01	0x05	PCI Device
0x12	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x13	0x01	0x01	Sub type – PCI
0x14	0x02	0x06	Length – 0x06 bytes
0x16	0x01	0x00	PCI Function
0x17	0x01	0x07	PCI Device
0x18	0x01	0x04	Generic Device Path Header – Type Media Device Path
0x19	0x01	0x08	Sub type – Relative Offset Range
0x1A	0x02	0x14	Length – 0x14 bytes

0x1C	0x08	0x8000	Start Address – Offset into PCI Option ROM
0x24	0x08	0x9FFF	End Address – Offset into PCI Option ROM
0x2C	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x2D	0x01	0xFF	Sub type – End of Entire Device Path
0x2E	0x02	0x04	Length – 0x04 bytes

The PCI Option ROM search may produce one or more Driver Image Handles for the PCI Controller that is associated with the PCI Option ROM. The PCI Bus Driver is responsible for producing a Bus Specific Driver Override Protocol instance for every PCI Controller has a PCI Option ROM that contains one or more UEFI Drivers. The Bus Specific Driver Override Protocol produces an ordered list of Driver Image Handles. The order that the UEFI Drivers are placed in the PCI Option ROM is the order of Driver Image Handles that must be returned by the Bus Specific Driver Override Protocol. This gives the party that builds the PCI Option ROM control over the order that the drivers are used in the Boot Service [EFI_BOOT_SERVICES.ConnectController\(\)](#).

13.4.2.2 PCI Device Driver Responsibilities

A PCI Device Driver should not be designed to care where it is stored. It can reside in a PCI Option ROM, the system's motherboard ROM, a hard drive, a CD-ROM drive, etc. All PCI Device Drivers are compiled and linked to generate a PE/COFF image. When a PE/COFF image is placed in a PCI Option ROM, it must follow the rules outlined in [Section 13.4.2](#). The recommended image layout is to insert an EFI PCI Expansion ROM Header and a PCIR Data Structure in front of the PE/COFF image, and pad the entire image up to the next 512-byte boundary. [Figure 45](#) shows the format of a single PCI Device Driver that can be added to a PCI Option ROM.

Following are recommended layouts and flow charts for various types of driver signage and compression states for PCI device driver images. [Figure 45](#) shows an unsigned layout.

Figure 45. Unsigned PCI Driver Image Layout

[Figure 46](#) and [Figure 47](#) show a signed and compressed PCI device driver image flow chart and layout, respectively.

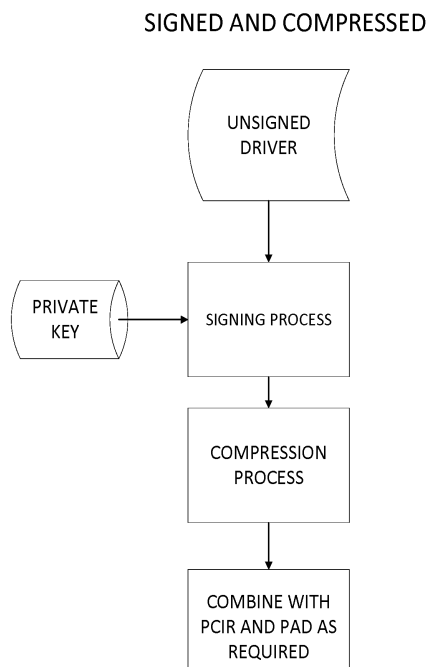

Figure 46. Signed and Compressed PCI Driver Image Flow

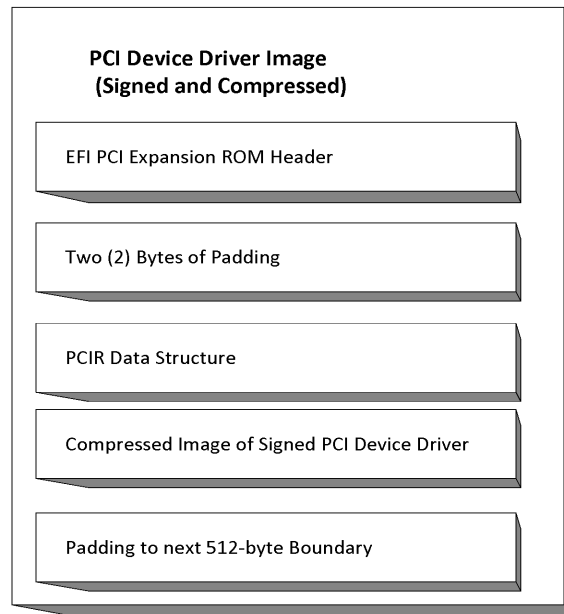

Figure 47. Signed and Compressed PCI Driver Image Layout

[Figure 48](#) and [Figure 49](#) show a signed but not compressed flow chart and a signed and uncompressed PCI device driver image layout, respectively.

SIGNED BUT NOT COMPRESSED

Figure 48. Signed but not Compressed PCI Driver Image Flow

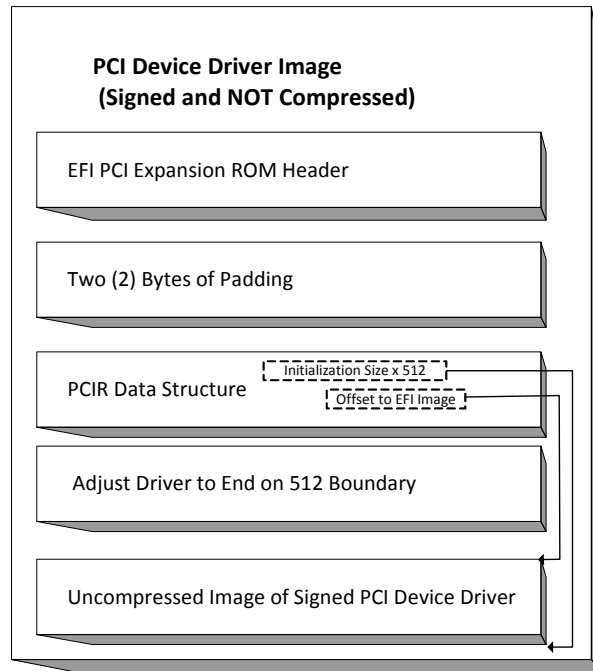

Figure 49. Signed and Uncompressed PCI Driver Image Layout

The field values for the EFI PCI Expansion ROM Header and the PCIR Data Structure would be as follows in this recommended PCI Driver image layout. An image must start at a 512-byte boundary, and the end of the image must be padded to the next 512-byte boundary.

Table 128. Recommended PCI Device Driver Layout

Offset	Byte Length	Value	Description
0x00	1	0x55	ROM Signature, byte 1
0x01	1	0xAA	ROM Signature, byte 2
0x02	2	XXXX	Initialization Size – size of this image in units of 512 bytes. The size includes this header
0x04	4	0x0EF1	Signature from EFI image header
0x08	2	XX 0x0B 0x0C	Subsystem Value from the PCI Driver's PE/COFF Image Header Subsystem Value for an EFI Boot Service Driver Subsystem Value for an EFI Runtime Driver
0x0a	2	XX 0x014C 0x0200 0x0EBC 0x8664 0x01c2 0xAA64	Machine type from the PCI Driver's PE/COFF Image Header IA-32 Machine Type Itanium processor type EFI Byte Code (EBC) Machine Type X64 Machine Type ARM Machine Type ARM 64-bit Machine Type

Offset	Byte Length	Value	Description
0x0C	2	XXXX 0x0000 0x0001	Compression Type Uncompressed Compressed following the UEFI Compression Algorithm.
0x0E	8	0x00	Reserved
0x16	2	0x0034	Offset to EFI Image
0x18	2	0x001C	Offset to PCIR Data Structure
0x1A	2	0x0000	Padding to align PCIR Data Structure on a 4 byte boundary
0x1C	4	'PCIR'	PCIR Data Structure Signature
0x20	2	XXXX	Vendor ID from the PCI Controller's Configuration Header
0x22	2	XXXX	Device ID from the PCI Controller's Configuration Header
0x24	2	0x0000	Reserved
0x26	2	0x0018	The length of the PCIR Data Structure in bytes
0x28	1	0x00	PCIR Data Structure Revision. Value for PCI 2.2 Option ROM
0x29	3	XXXX	Class Code from the PCI Controller's Configuration Header
0x2C	2	XXXX	Code Image Length in units of 512 bytes. Same as Initialization Size
0x2E	2	XXXX	Revision Level of the Code/Data. This field is ignored
0x30	1	0x03	Code Type
0x31	1	XX	Indicator. Bit 7 clear means another image follows. Bit 7 set means that this image is the last image in the PCI Option ROM. Bits 0–6 are reserved.
		0x00 0x80	Additional images follow this image in the PCI Option ROM This image is the last image in the PCI Option ROM
0x32	2	0x0000	Reserved
0x34	X	XXXX	The beginning of the PCI Device Driver's PE/COFF Image

13.4.3 Nonvolatile Storage

A PCI adapter may contain some form of nonvolatile storage. Since there are no standard access mechanisms for nonvolatile storage on PCI adapters, the PCI I/O Protocol does not provide any services for nonvolatile storage. However, a PCI Device Driver may choose to implement its own access mechanisms. If there is a private channel between a PCI Controller and a nonvolatile storage device, a PCI Device Driver can use it for configuration options or vital product data.

Note: *The fields `RomImage` and `RomSize` in the PCI I/O Protocol do not provide direct access to the PCI Option ROM on a PCI adapter. Instead, they provide access to a copy of the PCI Option ROM in memory. If the contents of the `RomImage` are modified, only the memory copy is updated. If a vendor wishes to update the contents of a PCI Option ROM, they must provide their own utility or driver to perform this task. There is no guarantee that the BAR for the PCI Option ROM is valid at the time that the utility or driver may execute, so the utility or driver must provide the code required to gain write access to the PCI Option ROM contents. The algorithm for gaining write access to a*

PCI Option ROM is both platform specific and adapter specific, so it is outside the scope of this document.

13.4.4 PCI Hot-Plug Events

It is possible to design a PCI Bus Driver to work with PCI Bus that conforms to the PCI Hot-Plug Specification. There are two levels of functionality that could be provided in the preboot environment. The first is to initialize the PCI Hot-Plug capable bus so it can be used by an operating system that also conforms to the PCI Hot-Plug Specification. This only affects the PCI Enumeration that is performed in either the PCI Bus Driver's initialization, or a firmware component that executes prior to the PCI Bus Driver's initialization. None of the PCI Device Drivers need to be aware of the fact that a PCI Controller may exist in a slot that is capable of a hot-plug event. Also, the addition, removal, and replacement of PCI adapters in the preboot environment would not be allowed.

The second level of functionality is to actually implement the full hot-plug capability in the PCI Bus Driver. This is not recommended because it adds a great deal of complexity to the PCI Bus Driver design with very little added value. However, there is nothing about the PCI Driver Model that would preclude this implementation. It would require using an event based periodic timer to monitor the hot-plug capable slots, and take advantage of the [EFI BOOT SERVICES.ConnectController \(\)](#) and [EFI BOOT SERVICES.DisconnectController \(\)](#) Boot Services to dynamically start and stop the drivers that manage the PCI controller that is being added, removed, or replaced. If the [EFI BOOT SERVICES.DisconnectController \(\)](#) Boot Service fails it must be retried via a periodic timer.

14

Protocols — SCSI Driver Models and Bus Support

The intent of this chapter is to specify a method of providing direct access to SCSI devices. These protocols provide services that allow a generic driver to produce the Block I/O protocol for SCSI disk devices, and allows an EFI utility to issue commands to any SCSI device. The main reason to provide such an access is to enable S.M.A.R.T. functionality during POST (i.e., issuing Mode Sense, Mode Select, and Log Sense to SCSI devices). This is accomplished by using a generic API such as SCSI Pass Thru. The use of this method will enable additional functionality in the future without modifying the EFI SCSI Pass Thru driver. SCSI Pass Thru is not limited to SCSI channels. It is applicable to all channel technologies that utilize SCSI commands such as SCSI, ATAPI, and Fibre Channel. This chapter describes the SCSI Driver Model. This includes the behavior of SCSI Bus Drivers, the behavior of SCSI Device Drivers, and a detailed description of the SCSI I/O Protocol. This chapter provides enough material to implement a SCSI Bus Driver, and the tools required to design and implement SCSI Device Drivers. It does not provide any information on specific SCSI devices.

14.1 SCSI Driver Model Overview

The EFI SCSI Driver Stack includes the SCSI Pass Thru Driver, SCSI Bus Driver and individual SCSI Device Drivers.

SCSI Pass Thru Driver: A SCSI Pass Through Driver manages a SCSI Host Controller that contains one or more SCSI Buses. It creates SCSI Bus Controller Handles for each SCSI Bus, and attaches Extended SCSI Pass Thru Protocol and Device Path Protocol to each handle the driver produced. Please refer to [Section 14.7](#) and [Appendix G](#) for details about the Extended SCSI Pass Thru Protocol.

SCSI Bus Driver: A SCSI Bus Driver manages a SCSI Bus Controller Handle that is created by SCSI Pass Thru Driver. It creates SCSI Device Handles for each SCSI Device Controller detected during SCSI Bus Enumeration, and attaches SCSI I/O Protocol and Device Path Protocol to each handle the driver produced.

SCSI Device Driver: A SCSI Device Driver manages one kind of SCSI Device. Device handles for SCSI Devices are created by SCSI Bus Drivers. A SCSI Device Driver could be a bus driver itself, and may create child handles. But most SCSI Device Drivers will be device drivers that do not create new handles. For the pure device driver, it attaches protocol instance to the device handle of the SCSI Device. These protocol instances are I/O abstractions that allow the SCSI Device to be used in the pre-boot environment. The most common I/O abstractions are used to boot an EFI compliant OS.

14.2 SCSI Bus Drivers

A SCSI Bus Driver manages a SCSI Bus Controller Handle. A SCSI Bus Controller Handle is created by a SCSI Pass Thru Driver and is abstracted in software with the Extended SCSI Pass Thru Protocol. A SCSI Bus Driver will manage handles that contain this protocol. [Figure 50](#) shows an example device handle for a SCSI Bus handle. It contains a Device Path Protocol instance and a Extended SCSI Pass Thru Protocol Instance.

Figure 50. Device Handle for a SCSI Bus Controller

14.2.1 Driver Binding Protocol for SCSI Bus Drivers

The Driver Binding Protocol contains three services. These are **Supported()**, **Start()**, and **Stop()**. **Supported()** tests to see if the SCSI Bus Driver can manage a device handle. A SCSI Bus Driver can only manage device handle that contain the Device Path Protocol and the Extended SCSI Pass Thru Protocol, so a SCSI Bus Driver must look for these two protocols on the device handle that is being tested.

The **Start()** function tells the SCSI Bus Driver to start managing a device handle. The device handle should support the protocols shown in [Figure 50](#). The Extended SCSI Pass Thru Protocol provides information about a SCSI Channel and the ability to communicate with any SCSI devices attached to that SCSI Channel.

The SCSI Bus Driver has the option of creating all of its children in one call to **Start()**, or spreading it across several calls to **Start()**. In general, if it is possible to design a bus driver to create one child at a time, it should do so to support the rapid boot capability in the UEFI Driver Model. Each of the child device handles created in **Start()** must contain a Device Path Protocol instance, and a SCSI I/O protocol instance. The SCSI I/O Protocol is described in [Section 14.4](#) and [Section 13.4](#). The format of device paths for SCSI Devices is described in [Section 14.5](#). [Figure 51](#) shows an example child device handle that is created by a SCSI Bus Driver for a SCSI Device.

Figure 51. Child Handle Created by a SCSI Bus Driver

A SCSI Bus Driver must perform several steps to manage a SCSI Bus.

1. Scan for the SCSI Devices on the SCSI Channel that connected to the SCSI Bus Controller. If a request is being made to scan only one SCSI Device, then only looks for the one specified. Create a device handle for the SCSI Device found.
2. Install a Device Path Protocol instance and a SCSI I/O Protocol instance on the device handle created for each SCSI Device.

The **Stop()** function tells the SCSI Bus Driver to stop managing a SCSI Bus. The **Stop()** function can destroy one or more of the device handles that were created on a previous call to **Start()**. If all of the child device handles have been destroyed, then **Stop()** will place the SCSI Bus Controller in a quiescent state. The functionality of **Stop()** mirrors **Start()**.

14.2.2 SCSI Enumeration

The purpose of the SCSI Enumeration is only to scan for the SCSI Devices attached to the specific SCSI channel. The SCSI Bus driver need not allocate resources for SCSI Devices (like PCI Bus Drivers do), nor need it connect a SCSI Device with its Device Driver (like USB Bus Drivers do). The details of the SCSI Enumeration is implementation specific, thus is out of the scope of this document.

14.3 SCSI Device Drivers

SCSI Device Drivers manage SCSI Devices. Device handles for SCSI Devices are created by SCSI Bus Drivers. A SCSI Device Driver could be a bus driver itself, and may create child handles. But most SCSI Device Drivers will be device drivers that do not create new handles. For the pure device driver, it attaches protocol instance to the device handle of the SCSI Device. These protocol instances are I/O abstractions that allow the SCSI Device to be used in the pre-boot environment. The most common I/O abstractions are used to boot an EFI compliant OS.

14.3.1 Driver Binding Protocol for SCSI Device Drivers

The Driver Binding Protocol contains three services. These are **Supported()**, **Start()**, and **Stop()**. **Supported()** tests to see if the SCSI Device Driver can manage a device handle. A SCSI Device Driver can only manage device handle that contain the Device Path Protocol and the

SCSI I/O Protocol, so a SCSI Device Driver must look for these two protocols on the device handle that is being tested. In addition, it needs to check to see if the device handle represents a SCSI Device that SCSI Device Driver knows how to manage. This is typically done by using the services of the SCSI I/O Protocol to see whether the device information retrieved is supported by the device driver.

The **Start ()** function tells the SCSI Device Driver to start managing a SCSI Device. A SCSI Device Driver could be a bus driver itself, and may create child handles. But most SCSI Device Drivers will be device drivers that do not create new handles. For the pure device driver, it installs one or more addition protocol instances on the device handle for the SCSI Device.

The **Stop ()** function mirrors the **Start ()** function, so the **Stop ()** function completes any outstanding transactions to the SCSI Device and removes the protocol interfaces that were installed in **Start ()**.

14.4 EFI SCSI I/O Protocol

This section defines the EFI SCSI I/O protocol. This protocol is used by code, typically drivers, running in the EFI boot services environment to access SCSI devices. In particular, functions for managing devices on SCSI buses are defined here.

The interfaces provided in the **EFI_SCSI_IO_PROTOCOL** are for performing basic operations to access SCSI devices.

EFI_SCSI_IO_PROTOCOL

This section provides a detailed description of the **EFI_SCSI_IO_PROTOCOL**.

Summary

Provides services to manage and communicate with SCSI devices.

GUID

```
#define EFI_SCSI_IO_PROTOCOL_GUID \
    {0x932f47e6,0x2362,0x4002,\
     {0x80,0x3e,0x3c,0xd5,0x4b,0x13,0x8f,0x85}}
```

Protocol Interface Structure

```
typedef struct _EFI_SCSI_IO_PROTOCOL {
    EFI_SCSI_IO_PROTOCOL_GET_DEVICE_TYPE           GetDeviceType;
    EFI_SCSI_IO_PROTOCOL_GET_DEVICE_LOCATION      GetDeviceLocation;
    EFI_SCSI_IO_PROTOCOL_RESET_BUS               ResetBus;
    EFI_SCSI_IO_PROTOCOL_RESET_DEVICE           ResetDevice;
    EFI_SCSI_IO_PROTOCOL_EXECUTE_SCSI_COMMAND   ExecuteScsiCommand;
    UINT32                                       IoAlign;
} EFI_SCSI_IO_PROTOCOL;
```

Parameters

<i>IoAlign</i>	Supplies the alignment requirement for any buffer used in a data transfer. <i>IoAlign</i> values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, <i>IoAlign</i> must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by <i>IoAlign</i> with no remainder.
<i>GetDeviceType</i>	Retrieves the information of the device type which the SCSI device belongs to. See GetDeviceType() .
<i>GetDeviceLocation</i>	Retrieves the device location information in the SCSI bus. See GetDeviceLocation() .
<i>ResetBus</i>	Resets the entire SCSI bus the SCSI device attaches to. See ResetBus() .
<i>ResetDevice</i>	Resets the SCSI Device that is specified by the device handle the SCSI I/O protocol attaches. See ResetDevice() .
<i>ExecuteScsiCommand</i>	Sends a SCSI command to the SCSI device and waits for the execution completion until an exit condition is met, or a timeout occurs. See ExecuteScsiCommand() .

Description

The **EFI_SCSI_IO_PROTOCOL** provides the basic functionalities to access and manage a SCSI Device. There is one **EFI_SCSI_IO_PROTOCOL** instance for each SCSI Device on a SCSI Bus. A device driver that wishes to manage a SCSI Device in a system will have to retrieve the **EFI_SCSI_IO_PROTOCOL** instance that is associated with the SCSI Device. A device handle for a SCSI Device will minimally contain an **EFI_DEVICE_PATH_PROTOCOL** instance and an **EFI_SCSI_IO_PROTOCOL** instance.

EFI_SCSI_IO_PROTOCOL.GetDeviceType()

Summary

Retrieves the device type information of the SCSI Device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SCSI_IO_PROTOCOL_GET_DEVICE_TYPE) (
    IN  EFI_SCSI_IO_PROTOCOL    *This,
    OUT UINT8                   *DeviceType
);
```

Parameters

<i>This</i>	A pointer to the EFI_SCSI_IO_PROTOCOL instance. Type EFI_SCSI_IO_PROTOCOL is defined in EFI_SCSI_IO_PROTOCOL .
<i>DeviceType</i>	A pointer to the device type information retrieved from the SCSI Device. See “Related Definitions” for the possible returned values of this parameter.

Description

This function is used to retrieve the SCSI device type information. This function is typically used for SCSI Device Drivers to quickly recognize whether the SCSI Device could be managed by it.

If *DeviceType* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. Otherwise, the device type is returned in *DeviceType* and **EFI_SUCCESS** is returned.

                                         // disk)
#define MFI_SCSI_IO_TYPE_OCRW        0x0F // Optical card reader/
                                         // writer device
#define MFI_SCSI_IO_TYPE_BRIDGE      0x10 // Bridge Controller
                                         // Commands
#define MFI_SCSI_IO_TYPE OSD         0x11 // Object-based Storage
                                         // Device
#define EFI_SCSI_IO_TYPE_RESERVED_LOW 0x12 // Reserved (low)
#define EFI_SCSI_IO_TYPE_RESERVED_HIGH 0x1E // Reserved (high)
#define EFI_SCSI_IO_TYPE_UNKNOWN     0x1F // Unknown no device type

```

Status Codes Returned

EFI_SUCCESS	Retrieves the device type information successfully.
EFI_INVALID_PARAMETER	The DeviceType is NULL .

EFI_SCSI_IO_PROTOCOL.GetDeviceLocation()

Summary

Retrieves the SCSI device location in the SCSI channel.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SCSI_IO_PROTOCOL_GET_DEVICE_LOCATION) (
    IN EFI_SCSI_IO_PROTOCOL  *This,
    IN OUT UINT8              **Target,
    OUT  UINT64               *Lun
);
```

Parameters

<i>This</i>	A pointer to the EFI_SCSI_IO_PROTOCOL instance. Type EFI_SCSI_IO_PROTOCOL is defined in EFI_SCSI_IO_PROTOCOL .
<i>Target</i>	A pointer to the Target Array which represents the ID of a SCSI device on the SCSI channel.
<i>Lun</i>	A pointer to the Logical Unit Number of the SCSI device on the SCSI channel.

Description

This function is used to retrieve the SCSI device location in the SCSI bus. The device location is determined by a (Target, Lun) pair. This function allows a SCSI Device Driver to retrieve its location on the SCSI channel, and may use the Extended SCSI Pass Thru Protocol to access the SCSI device directly.

If *Target* or *Lun* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. Otherwise, the device location is returned in *Target* and *Lun*, and **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	Retrieves the device location successfully.
EFI_INVALID_PARAMETER	Target or Lun is NULL .

EFI_SCSI_IO_PROTOCOL.ResetBus()

Summary

Resets the SCSI Bus that the SCSI Device is attached to.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SCSI_IO_PROTOCOL_RESET_BUS) (
    IN EFI_SCSI_IO_PROTOCOL      *This
);
```

Parameters

This A pointer to the **EFI_SCSI_IO_PROTOCOL** instance. Type **EFI_SCSI_IO_PROTOCOL** is defined in [EFI_SCSI_IO_PROTOCOL](#).

Description

This function provides the mechanism to reset the whole SCSI bus that the specified SCSI Device is connected to. Some SCSI Host Controller may not support bus reset, if so, **EFI_UNSUPPORTED** is returned. If a device error occurs while executing that bus reset operation, then **EFI_DEVICE_ERROR** is returned. If a timeout occurs during the execution of the bus reset operation, then **EFI_TIMEOUT** is returned. If the bus reset operation is completed, then **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The SCSI bus is reset successfully.
EFI_DEVICE_ERROR	Errors encountered when resetting the SCSI bus.
EFI_UNSUPPORTED	The bus reset operation is not supported by the SCSI Host Controller.
EFI_TIMEOUT	A timeout occurred while attempting to reset the SCSI bus.

EFI_SCSI_IO_PROTOCOL.ResetDevice()

Summary

Resets the SCSI Device that is specified by the device handle that the SCSI I/O Protocol is attached.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SCSI_IO_PROTOCOL_RESET_DEVICE) (
    IN EFI_SCSI_IO_PROTOCOL      *This
);
```

Parameters

This A pointer to the **EFI_SCSI_IO_PROTOCOL** instance. Type **EFI_SCSI_IO_PROTOCOL** is defined in [EFI_SCSI_IO_PROTOCOL](#).

Description

This function provides the mechanism to reset the SCSI Device. If the SCSI bus does not support a device reset operation, then **EFI_UNSUPPORTED** is returned. If a device error occurs while executing that device reset operation, then **EFI_DEVICE_ERROR** is returned. If a timeout occurs during the execution of the device reset operation, then **EFI_TIMEOUT** is returned. If the device reset operation is completed, then **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	Reset the SCSI Device successfully.
EFI_DEVICE_ERROR	Errors are encountered when resetting the SCSI Device.
EFI_UNSUPPORTED	The SCSI bus does not support a device reset operation.
EFI_TIMEOUT	A timeout occurred while attempting to reset the SCSI Device.

EFI_SCSI_IO_PROTOCOL.ExecuteScsiCommand()

Summary

Sends a SCSI Request Packet to the SCSI Device for execution.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SCSI_IO_PROTOCOL_EXECUTE_SCSI_COMMAND) (
    IN      EFI_SCSI_IO_PROTOCOL          *This,
    IN OUT  EFI_SCSI_IO_SCSI_REQUEST_PACKET *Packet,
    IN      EFI_EVENT                     Event OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_SCSI_IO_PROTOCOL instance. Type EFI_SCSI_IO_PROTOCOL is defined in EFI_SCSI_IO_PROTOCOL .
<i>Packet</i>	The SCSI request packet to send to the SCSI Device specified by the device handle. See “Related Definitions” for a description of EFI_SCSI_IO_SCSI_REQUEST_PACKET .
<i>Event</i>	If the SCSI bus where the SCSI device is attached does not support non-blocking I/O, then <i>Event</i> is ignored, and blocking I/O is performed. If <i>Event</i> is NULL , then blocking I/O is performed. If <i>Event</i> is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and <i>Event</i> will be signaled when the SCSI Request Packet completes.

Related Definitions

```
typedef struct {
    UINT64      Timeout;
    VOID        *InDataBuffer;
    VOID        *OutDataBuffer;
    VOID        *SenseData;
    VOID        *Cdb;
    UINT32      InTransferLength;
    UINT32      OutTransferLength;
    UINT8       CdbLength;
    UINT8       DataDirection;
    UINT8       HostAdapterStatus;
    UINT8       TargetStatus;
    UINT8       SenseDataLength;
} EFI_SCSI_IO_SCSI_REQUEST_PACKET;
```

<i>Timeout</i>	The timeout, in 100 ns units, to use for the execution of this SCSI Request Packet. A <i>Timeout</i> value of 0 means that this function
----------------	--

will wait indefinitely for the SCSI Request Packet to execute. If *Timeout* is greater than zero, then this function will return **EFI_TIMEOUT** if the time required to execute the SCSI Request Packet is greater than *Timeout*.

<i>DataBuffer</i>	A pointer to the data buffer to transfer from or to the SCSI device.
<i>InDataBuffer</i>	A pointer to the data buffer to transfer between the SCSI controller and the SCSI device for SCSI READ command. For all SCSI WRITE Commands this must point to NULL .
<i>OutDataBuffer</i>	A pointer to the data buffer to transfer between the SCSI controller and the SCSI device for SCSI WRITE command. For all SCSI READ commands this field must point to NULL .
<i>SenseData</i>	A pointer to the sense data that was generated by the execution of the SCSI Request Packet.
<i>Cdb</i>	A pointer to buffer that contains the Command Data Block to send to the SCSI device.
<i>InTransferLength</i>	On Input, the size, in bytes, of <i>InDataBuffer</i> . On output, the number of bytes transferred between the SCSI controller and the SCSI device. If <i>InTransferLength</i> is larger than the SCSI controller can handle, no data will be transferred, <i>InTransferLength</i> will be updated to contain the number of bytes that the SCSI controller is able to transfer, and EFI_BAD_BUFFER_SIZE will be returned.
<i>OutTransferLength</i>	On Input, the size, in bytes of <i>OutDataBuffer</i> . On Output, the Number of bytes transferred between SCSI Controller and the SCSI device. If <i>OutTransferLength</i> is larger than the SCSI controller can handle, no data will be transferred, <i>OutTransferLength</i> will be updated to contain the number of bytes that the SCSI controller is able to transfer, and EFI_BAD_BUFFER_SIZE will be returned.
<i>CdbLength</i>	The length, in bytes, of the buffer <i>Cdb</i> . The standard values are 6, 10, 12, and 16, but other values are possible if a variable length <i>CDB</i> is used.
<i>DataDirection</i>	The direction of the data transfer. 0 for reads, 1 for writes. A value of 2 is Reserved for Bi-Directional SCSI commands. For example XDREADWRITE. All other values are reserved, and must not be used.
<i>HostAdapterStatus</i>	The status of the SCSI Host Controller that produces the SCSI bus where the SCSI device attached when the SCSI Request Packet was executed on the SCSI Controller. See the possible values listed below.
<i>TargetStatus</i>	The status returned by the SCSI device when the SCSI Request Packet was executed. See the possible values listed below.
<i>SenseDataLength</i>	On input, the length in bytes of the <i>SenseData</i> buffer. On output, the number of bytes written to the <i>SenseData</i> buffer.

```

Description

This function sends the SCSI Request Packet specified by *Packet* to the SCSI Device.

If the SCSI Bus supports non-blocking I/O and *Event* is not **NULL**, then this function will return immediately after the command is sent to the SCSI Device, and will later signal *Event* when the command has completed. If the SCSI Bus supports non-blocking I/O and *Event* is **NULL**, then this function will send the command to the SCSI Device and block until it is complete. If the SCSI Bus does not support non-blocking I/O, the *Event* parameter is ignored, and the function will send the command to the SCSI Device and block until it is complete.

If *Packet* is successfully sent to the SCSI Device, then **EFI_SUCCESS** is returned.

If *Packet* cannot be sent because there are too many packets already queued up, then **EFI_NOT_READY** is returned. The caller may retry *Packet* at a later time.

If a device error occurs while sending the *Packet*, then **EFI_DEVICE_ERROR** is returned.

If a timeout occurs during the execution of *Packet*, then **EFI_TIMEOUT** is returned.

If any field of *Packet* is invalid, then **EFI_INVALID_PARAMETER** is returned.

If the data buffer described by *DataBuffer* and *TransferLength* is too big to be transferred in a single command, then **EFI_BAD_BUFFER_SIZE** is returned. The number of bytes actually transferred is returned in *TransferLength*.

If the command described in *Packet* is not supported by the SCSI Host Controller that produces the SCSI bus, then **EFI_UNSUPPORTED** is returned.

If **EFI_SUCCESS**, **EFI_BAD_BUFFER_SIZE**, **EFI_DEVICE_ERROR**, or **EFI_TIMEOUT** is returned, then the caller must examine the status fields in *Packet* in the following precedence order: *HostAdapterStatus* followed by *TargetStatus* followed by *SenseDataLength*, followed by *SenseData*. If non-blocking I/O is being used, then the status fields in *Packet* will not be valid until the *Event* associated with *Packet* is signaled.

If **EFI_NOT_READY**, **EFI_INVALID_PARAMETER** or **EFI_UNSUPPORTED** is returned, then *Packet* was never sent, so the status fields in *Packet* are not valid. If non-blocking I/O is being used, the *Event* associated with *Packet* will not be signaled.

Status Codes Returned

EFI_SUCCESS	The SCSI Request Packet was sent by the host. For read and bi-directional commands, <i>InTransferLength</i> bytes were transferred to <i>InDataBuffer</i> . For write and bi-directional commands, <i>OutTransferLength</i> bytes were transferred from <i>OutDataBuffer</i> . See <i>HostAdapterStatus</i> , <i>TargetStatus</i> , <i>SenseDataLength</i> , and <i>SenseData</i> in that order for additional status information.
EFI_BAD_BUFFER_SIZE	The SCSI Request Packet was not executed. For read and bi-directional commands, the number of bytes that could be transferred is returned in <i>InTransferLength</i> . For write and bi-directional commands, the number of bytes that could be transferred is returned in <i>OutTransferLength</i> . See <i>HostAdapterStatus</i> and <i>TargetStatus</i> in that order for additional status information.
EFI_NOT_READY	The SCSI Request Packet could not be sent because there are too many SCSI Command Packets already queued. The caller may retry again later.

EFI_DEVICE_ERROR	A device error occurred while attempting to send the SCSI Request Packet. See <i>HostAdapterStatus</i> , <i>TargetStatus</i> , <i>SenseDataLength</i> , and <i>SenseData</i> in that order for additional status information.
EFI_INVALID_PARAMETER	The contents of <i>CommandPacket</i> are invalid. The SCSI Request Packet was not sent, so no additional status information is available.
EFI_UNSUPPORTED	The command described by the SCSI Request Packet is not supported by the SCSI initiator (i.e., SCSI Host Controller). The SCSI Request Packet was not sent, so no additional status information is available.
EFI_TIMEOUT	A timeout occurred while waiting for the SCSI Request Packet to execute. See <i>HostAdapterStatus</i> , <i>TargetStatus</i> , <i>SenseDataLength</i> , and <i>SenseData</i> in that order for additional status information.

14.5 SCSI Device Paths

An **EFI_SCSI_IO_PROTOCOL** must be installed on a handle for its services to be available to SCSI device drivers. In addition to the **EFI_SCSI_IO_PROTOCOL**, an **EFI_DEVICE_PATH_PROTOCOL** must also be installed on the same handle. See [Section 9](#) for detailed description of the **EFI_DEVICE_PATH_PROTOCOL**.

The SCSI Driver Model defined in this document can support the SCSI channel generated or emulated by multiple architectures, such as Parallel SCSI, ATAPI, Fibre Channel, InfiniBand, and other future channel types. In this section, there are four example device paths provided, including SCSI device path, ATAPI device path, Fibre Channel device path and InfiniBand device path.

14.5.1 SCSI Device Path Example

[Table 129](#) shows an example device path for a SCSI device controller on a desktop platform. This SCSI device controller is connected to a SCSI channel that is generated by a PCI SCSI host controller. The PCI SCSI host controller generates a single SCSI channel, it is located at PCI device number 0x07 and PCI function 0x00, and is directly attached to a PCI root bridge. The SCSI device controller is assigned SCSI Id 2, and its LUN is 0.

This sample device path consists of an ACPI Device Path Node, a PCI Device Path Node, a SCSI Node, and a Device Path End Structure. The `_HID` and `_UID` must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

ACPI (PNP0A03, 0) / PCI (7, 0) / SCSI (2, 0) .

Table 129. SCSI Device Path Examples

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path

Byte Offset	Byte Length	Data	Description
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x07	PCI Function
0x11	0x01	0x00	PCI Device
0x12	0x01	0x03	Generic Device Path Header – Type Message Device Path
0x13	0x01	0x02	Sub type – SCSI
0x14	0x02	0x08	Length – 0x08 bytes
0x16	0x02	0x0002	Target ID on the SCSI bus (PUN)
0x18	0x02	0x0000	Logical Unit Number (LUN)
0x1A	0x01	0xff	Generic Device Path Header – Type End of Hardware Device Path
0x1B	0x01	0xFF	Sub type – End of Entire Device Path
0x1C	0x02	0x04	Length – 0x04 bytes

14.5.2 ATAPI Device Path Example

[Table 130](#) shows an example device path for an ATAPI device on a desktop platform. This ATAPI device is connected to the IDE bus on Primary channel, and is configured as the Master device on the channel. The IDE bus is generated by the IDE controller that is a PCI device. It is located at PCI device number 0x1F and PCI function 0x01, and is directly attached to a PCI root bridge.

This sample device path consists of an ACPI Device Path Node, a PCI Device Path Node, an ATAPI Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

ACPI (PNP0A03, 0) / PCI (7, 0) / ATA (Primary, Master, 0) .

Table 130. ATAPI Device Path Examples

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path

Byte Offset	Byte Length	Data	Description
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x07	PCI Function
0x11	0x01	0x00	PCI Device
0x12	0x01	0x03	Generic Device Path Header – Type Message Device Path
0x13	0x01	0x01	Sub type – ATAPI
0x14	0x02	0x08	Length – 0x08 bytes
0x16	0x01	0x00	PrimarySecondary – Set to zero for primary or one for secondary.
0x17	0x01	0x00	SlaveMaster – set to zero for master or one for slave.
0x18	0x02	0x0000	Logical Unit Number, LUN.
0x1A	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x1B	0x01	0xFF	Sub type – End of Entire Device Path
0x1C	0x02	0x04	Length – 0x04 bytes

14.5.3 Fibre Channel Device Path Example

[Table 131](#) shows an example device path for an SCSI device that is connected to a Fibre Channel Port on a desktop platform. The Fibre Channel Port is a PCI device that is located at PCI device number 0x08 and PCI function 0x00, and is directly attached to a PCI root bridge. The Fibre Channel Port is addressed by the World Wide Number, and is assigned as X (X is a 64bit value); the SCSI device’s Logical Unit Number is 0.

This sample device path consists of an ACPI Device Path Node, a PCI Device Path Node, a Fibre Channel Device Path Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

ACPI (PNP0A03, 0) / PCI (8, 0) / Fibre (X, 0) .

Table 131. Fibre Channel Device Path Examples

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x08	PCI Function
0x11	0x01	0x00	PCI Device

Byte Offset	Byte Length	Data	Description
0x12	0x01	0x03	Generic Device Path Header – Type Message Device Path
0x13	0x01	0x02	Sub type – Fibre Channel
0x14	0x02	0x24	Length – 0x24 bytes
0x16	0x04	0x00	Reserved
0x1A	0x08	X	Fibre Channel World Wide Number
0x22	0x08	0x00	Fibre Channel Logical Unit Number (LUN).
0x2A	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x2B	0x01	0xFF	Sub type – End of Entire Device Path
0x2C	0x02	0x04	Length – 0x04 bytes

14.5.4 InfiniBand Device Path Example

[Table 132](#) shows an example device path for a SCSI device in an InfiniBand Network. This SCSI device is connected to a single SCSI channel generated by a SCSI Host Adapter, and the SCSI Host Adapter is an end node in the InfiniBand Network. The SCSI Host Adapter is a PCI device that is located at PCI device number 0x07 and PCI function 0x00, and is directly attached to a PCI root bridge. The SCSI device is addressed by the (IOU X, IOC Y, DeviceId Z) in the InfiniBand Network. (X, Y, Z are EUI-64 compliant identifiers).

This sample device path consists of an ACPI Device Path Node, a PCI Device Path Node, an InfiniBand Node, and a Device Path End Structure. The `_HID` and `_UID` must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

ACPI (PNP0A03, 0) / PCI (7, 0) / Infiniband (X, Y, Z) .

Table 132. InfiniBand Device Path Examples

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	<code>_HID</code> PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	<code>_UID</code>
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x07	PCI Function
0x11	0x01	0x00	PCI Device
0x12	0x01	0x03	Generic Device Path Header – Type Message Device Path
0x13	0x01	0x09	Sub type – InfiniBand
0x14	0x02	0x20	Length – 0x20 bytes

Byte Offset	Byte Length	Data	Description
0x16	0x04	0x00	Reserved
0x1A	0x08	X	64bit node GUID of the IOU
0x22	0x08	Y	64bit GUID of the IOC
0x2A	0x08	Z	64bit persistent ID of the device.
0x32	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x33	0x01	0xFF	Sub type – End of Entire Device Path
0x34	0x02	0x04	Length – 0x04 bytes

14.6 SCSI Pass Thru Device Paths

An [EFI EXT SCSI PASS THRU PROTOCOL](#) must be installed on a handle for its services to be available to UEFI drivers and applications. In addition to the [EFI EXT SCSI PASS THRU PROTOCOL](#), an [EFI DEVICE PATH PROTOCOL](#) must also be installed on the same handle. See [Section 9](#) for a detailed description of the [EFI_DEVICE_PATH_PROTOCOL](#).

A device path describes the location of a hardware component in a system from the processor's point of view. This includes the list of busses that lie between the processor and the SCSI controller. The *EFI Specification* takes advantage of the *ACPI Specification* to name system components. For the following set of examples, a PCI SCSI controller is assumed. The examples will show a SCSI controller on the root PCI bus, and a SCSI controller behind a PCI-PCI bridge. In addition, an example of a multichannel SCSI controller will be shown.

[Table 133](#) shows an example device path for a single channel PCI SCSI controller that is located at PCI device number 0x07 and PCI function 0x00, and is directly attached to a PCI root bridge. This device path consists of an ACPI Device Path Node, a PCI Device Path Node, and a Device Path End Structure. The `_HID` and `_UID` must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

`ACPI (PNP0A03, 0) / PCI (7, 0) .`

Table 133. Single Channel PCI SCSI Controller

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	<code>_HID</code> PNP0A03 – 0x41D0 represents the compressed string 'PNP' and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	<code>_UID</code>
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes

Byte Offset	Byte Length	Data	Description
0x10	0x01	0x00	PCI Function
0x11	0x01	0x07	PCI Device
0x12	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x13	0x01	0xFF	Sub type – End of Entire Device Path
0x14	0x02	0x04	Length – 0x04 bytes

[Table 134](#) shows an example device path for a single channel PCI SCSI controller that is located behind a PCI to PCI bridge at PCI device number 0x07 and PCI function 0x00. The PCI to PCI bridge is directly attached to a PCI root bridge, and it is at PCI device number 0x05 and PCI function 0x00. This device path consists of an ACPI Device Path Node, two PCI Device Path Nodes, and a Device Path End Structure. The `_HID` and `_UID` must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

ACPI (PNP0A03, 0) / PCI (5, 0) / PCI (7, 0) .

Table 134. Single Channel PCI SCSI Controller behind a PCI Bridge

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header – Type ACPI Device Path
0x01	0x01	0x01	Sub type – ACPI Device Path
0x02	0x02	0x0C	Length – 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	<code>_HID</code> PNP0A03 – 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	<code>_UID</code>
0x0C	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x0D	0x01	0x01	Sub type – PCI
0x0E	0x02	0x06	Length – 0x06 bytes
0x10	0x01	0x00	PCI Function
0x11	0x01	0x05	PCI Device
0x12	0x01	0x01	Generic Device Path Header – Type Hardware Device Path
0x13	0x01	0x01	Sub type – PCI
0x14	0x02	0x06	Length – 0x06 bytes
0x16	0x01	0x00	PCI Function
0x17	0x01	0x07	PCI Device
0x18	0x01	0xFF	Generic Device Path Header – Type End of Hardware Device Path
0x19	0x01	0xFF	Sub type – End of Entire Device Path
0x1A	0x02	0x04	Length – 0x04 bytes

[Table 135](#) shows an example device path for channel #3 of a four channel PCI SCSI controller that is located behind a PCI to PCI bridge at PCI device number 0x07 and PCI function 0x00. The PCI to

PCI bridge is directly attached to a PCI root bridge, and it is at PCI device number 0x05 and PCI function 0x00. This device path consists of an ACPI Device Path Node, two PCI Device Path Nodes, a Controller Node, and a Device Path End Structure. The `_HID` and `_UID` must match the ACPI table description of the PCI Root Bridge. The shorthand notation of the device paths for all four of the SCSI channels are listed below. [Table 135](#) shows the last device path listed.

ACPI (PNP0A03, 0) / PCI (5, 0) / PCI (7, 0) / Ctrl1 (0)
ACPI (PNP0A03, 0) / PCI (5, 0) / PCI (7, 0) / Ctrl1 (1)
ACPI (PNP0A03, 0) / PCI (5, 0) / PCI (7, 0) / Ctrl1 (2)
ACPI (PNP0A03, 0) / PCI (5, 0) / PCI (7, 0) / Ctrl1 (3)

Table 135. Channel #3 of a PCI SCSI Controller behind a PCI Bridge

Byte Offset	Byte Length	Data	Description

0x21	0x01	0xFF	Sub type – End of Entire Device Path
0x22	0x02	0x04	Length – 0x04 bytes

14.7 Extended SCSI Pass Thru Protocol

This section defines the Extended SCSI Pass Thru Protocol. This protocol allows information about a SCSI channel to be collected, and allows SCSI Request Packets to be sent to any SCSI devices on a SCSI channel even if those devices are not boot devices. This protocol is attached to the device

handle of each SCSI channel in a system that the protocol supports, and can be used for diagnostics. It may also be used to build a Block I/O driver for SCSI hard drives and SCSI CD-ROM or DVD drives to allow those devices to become boot devices. As ATAPI cmds are derived from SCSI cmds, the above statements also are applicable for ATAPI devices attached to a ATA controller. Packet-based commands(ATAPI cmds) would be sent to ATAPI devices only through the Extended SCSI Pass Thru Protocol.

EFI_EXT_SCSI_PASS_THRU_PROTOCOL

This section provides a detailed description of the **EFI_EXT_SCSI_PASS_THRU_PROTOCOL**.

Summary

Provides services that allow SCSI Pass Thru commands to be sent to SCSI devices attached to a SCSI channel. It also allows packet-based commands (ATAPI cmds) to be sent to ATAPI devices attached to a ATA controller.

GUID

```
#define EFI_EXT_SCSI_PASS_THRU_PROTOCOL_GUID \
  {0x143b7632, 0xb81b, 0x4cb7, \
   {0xab, 0xd3, 0xb6, 0x25, 0xa5, 0xb9, 0xbf, 0xfe}}
```

Protocol Interface Structure

```
typedef struct _EFI_EXT_SCSI_PASS_THRU_PROTOCOL {
  EFI_EXT_SCSI_PASS_THRU_MODE           *Mode;
  EFI_EXT_SCSI_PASS_THRU_PASSTHRU      PassThru;
  EFI_EXT_SCSI_PASS_THRU_GET_NEXT_TARGET_LUN GetNextTargetLun;
  EFI_EXT_SCSI_PASS_THRU_BUILD_DEVICE_PATH BuildDevicePath;
  EFI_EXT_SCSI_PASS_THRU_GET_TARGET_LUN  GetTargetLun;
  EFI_EXT_SCSI_PASS_THRU_RESET_CHANNEL   ResetChannel;
  EFI_EXT_SCSI_PASS_THRU_RESET_TARGET_LUN ResetTargetLun;
  EFI_EXT_SCSI_PASS_THRU_GET_NEXT_TARGET GetNextTarget;
} EFI_EXT_SCSI_PASS_THRU_PROTOCOL;
```

Parameters

<i>Mode</i>	A pointer to the EFI_EXT_SCSI_PASS_THRU_MODE data for this SCSI channel. EFI_EXT_SCSI_PASS_THRU_MODE is defined in “Related Definitions” below.
<i>PassThru</i>	Sends a SCSI Request Packet to a SCSI device that is Connected to the SCSI channel. See the PassThru() function description.
<i>GetNextTargetLun</i>	Retrieves the list of legal Target IDs and LUNs for the SCSI devices on a SCSI channel. See the GetNextTargetLun() function description.
<i>BuildDevicePath</i>	Allocates and builds a device path node for a SCSI Device on a SCSI channel. See the BuildDevicePath() function description.

<i>GetTargetLun</i>	Translates a device path node to a Target ID and LUN. See the GetTargetLun() function description.
<i>ResetChannel</i>	Resets the SCSI channel. This operation resets all the SCSI devices connected to the SCSI channel. See the ResetChannel() function description.
<i>ResetTargetLun</i>	Resets a SCSI device that is connected to the SCSI channel. See the ResetTargetLun() function description.
<i>GetNextTartget</i>	Retrieves the list of legal Target IDs for the SCSI devices on a SCSI channel. See the GetNextTarget() function description.

The following data values in the **EFI_EXT_SCSI_PASS_THRU_MODE** interface are read-only.

<i>AdapterId</i>	The Target ID of the host adapter on the SCSI channel.
<i>Attributes</i>	Additional information on the attributes of the SCSI channel. See “Related Definitions” below for the list of possible attributes.
<i>IoAlign</i>	Supplies the alignment requirement for any buffer used in a data transfer. <i>IoAlign</i> values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, <i>IoAlign</i> must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by <i>IoAlign</i> with no remainder.

Related Definitions

```
typedef struct {
    UINT32  AdapterId;
    UINT32  Attributes;
    UINT32  IoAlign;
} EFI_EXT_SCSI_PASS_THRU_MODE;

#define TARGET_MAX_BYTES0x10
#define EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_PHYSICAL    0x0001
#define EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL     0x0002
#define EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_NONBLOCKIO 0x0004
```

EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_PHYSICAL

If this bit is set, then the **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** interface is for physical devices on the SCSI channel.

EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL

If this bit is set, then the **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** interface is for logical devices on the SCSI channel.

EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_NONBLOCKIO

If this bit is set, then the **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** interface supports non blocking I/O. Every **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** must support blocking I/O. The support of nonblocking I/O is optional.

Description

The **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** provides information about a SCSI channel and the ability to send SCSI Request Packets to any SCSI device attached to that SCSI channel. The information includes the Target ID of the host controller on the SCSI channel and the attributes of the SCSI channel.

The printable name for the SCSI controller, and the printable name of the SCSI channel can be provided through the **EFI_COMPONENT_NAME2_PROTOCOL** for multiple languages.

The *Attributes* field of the **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** interface tells if the interface is for physical SCSI devices or logical SCSI devices. Drivers for non-RAID SCSI controllers will set both the **EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_PHYSICAL**, and the **EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL** bits.

Drivers for RAID controllers that allow access to the physical devices and logical devices will produce two **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** interfaces: one with just the **EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_PHYSICAL** bit set and another with just the **EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL** bit set. One interface can be used to access the physical devices attached to the RAID controller, and the other can be used to access the logical devices attached to the RAID controller for its current configuration.

Drivers for RAID controllers that do not allow access to the physical devices will produce one **EFI_EXT_SCSI_PASS_THROUGH_PROTOCOL** interface with just the **EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL** bit set. The interface for logical devices can also be used by a file system driver to mount the RAID volumes. An **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** with neither **EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL** nor **EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_PHYSICAL** set is an illegal configuration.

The Attributes field also contains the **EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_NONBLOCKIO** bit. All **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** interfaces must support blocking I/O. If this bit is set, then the interface support both blocking I/O and nonblocking I/O.

Each **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** instance must have an associated device path. Typically this will have an *ACPI* device path node and a *PCI* device path node, although variation will exist. For a SCSI controller that supports only one channel per PCI bus/device/function, it is recommended, but not required, that an additional *Controller* device path node (for controller 0) be appended to the device path.

For a SCSI controller that supports multiple channels per PCI bus/device/function, it is required that a *Controller* device path node be appended for each channel.

Additional information about the SCSI channel can be obtained from protocols attached to the same handle as the **EFI_EXT_SCSI_PASS_THRU_PROTOCOL**, or one of its parent handles. This would include the device I/O abstraction used to access the internal registers and functions of the SCSI controller.

EFI_EXT_SCSI_PASS_THRU_PROTOCOL.PassThru()

Summary

Sends a SCSI Request Packet to a SCSI device that is attached to the SCSI channel. This function supports both blocking I/O and nonblocking I/O. The blocking I/O functionality is required, and the nonblocking I/O functionality is optional.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EXT_SCSI_PASS_THRU_PASSTHRU) (
    IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL    *This,
    IN UINT8                               *Target,
    IN UINT64                              Lun,
    IN OUT EFI_EXT_SCSI_PASS_THRU_SCSI_REQUEST_PACKET *Packet,
    IN EFI_EVENT                           Event OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_EXT_SCSI_PASS_THRU_PROTOCOL instance. Type EFI_EXT_SCSI_PASS_THRU_PROTOCOL is defined in Section 14.7 .
<i>Target</i>	The Target is an array of size TARGET_MAX_BYTES and it represents the id of the SCSI device to send the SCSI Request Packet. Each transport driver may chose to utilize a subset of this size to suit the needs of transport target representation. For example, a Fibre Channel driver may use only 8 bytes (WWN) to represent an FC target.
<i>Lun</i>	The LUN of the SCSI device to send the SCSI Request Packet.
<i>Packet</i>	A pointer to the SCSI Request Packet to send to the SCSI device specified by <i>Target</i> and <i>Lun</i> . See “Related Definitions” below for a description of EFI_EXT_SCSI_PASS_THRU_SCSI_REQUEST_PACKET .
<i>Event</i>	If nonblocking I/O is not supported then <i>Event</i> is ignored, and blocking I/O is performed. If <i>Event</i> is NULL , then blocking I/O is performed. If <i>Event</i> is not NULL and non blocking I/O is supported, then nonblocking I/O is performed, and <i>Event</i> will be signaled when the SCSI Request Packet completes.

Related Definitions

```
typedef struct {
    UINT64    Timeout;
    VOID      *InDataBuffer;
    VOID      *OutDataBuffer;
    VOID      *SenseData;
    VOID      *Cdb;
    UINT32    InTransferLength;
    UINT32    OutTransferLength;
    UINT8     CdbLength;
    UINT8     DataDirection;
    UINT8     HostAdapterStatus;
    UINT8     TargetStatus;
    UINT8     SenseDataLength;
} EFI_EXT_SCSI_PASS_THRU_SCSI_REQUEST_PACKET;
```

<i>Timeout</i>	The timeout, in 100 ns units, to use for the execution of this SCSI Request Packet. A <i>Timeout</i> value of 0 means that this function will wait indefinitely for the SCSI Request Packet to execute. If <i>Timeout</i> is greater than zero, then this function will return EFI_TIMEOUT if the time required to execute the SCSI Request Packet is greater than <i>Timeout</i> .
<i>InDataBuffer</i>	A pointer to the data buffer to transfer between the SCSI controller and the SCSI device for read and bidirectional commands. For all write and non data commands where <i>InTransferLength</i> is 0 this field is optional and may be NULL . If this field is not NULL , then it must be aligned on the boundary specified by the <i>IoAlign</i> field in the EFI_EXT_SCSI_PASS_THRU_MODE structure.
<i>OutDataBuffer</i>	A pointer to the data buffer to transfer between the SCSI controller and the SCSI device for write or bidirectional commands. For all read and non data commands where <i>OutTransferLength</i> is 0 this field is optional and may be NULL . If this field is not NULL , then it must be aligned on the boundary specified by the <i>IoAlign</i> field in the EFI_EXT_SCSI_PASS_THRU_MODE structure.
<i>SenseData</i>	A pointer to the sense data that was generated by the execution of the SCSI Request Packet. If <i>SenseDataLength</i> is 0, then this field is optional and may be NULL . It is strongly recommended that a sense data buffer of at least 252 bytes be provided to guarantee the entire sense data buffer generated from the execution of the SCSI Request Packet can be returned. If this field is not NULL , then it must be aligned to the boundary specified in the <i>IoAlign</i> field in the EFI_EXT_SCSI_PASS_THRU_MODE structure.
<i>Cdb</i>	A pointer to buffer that contains the Command Data Block to send to the SCSI device specified by <i>Target</i> and <i>Lun</i> .

InTransferLength On Input, the size, in bytes, of *InDataBuffer*. On output, the number of bytes transferred between the SCSI controller and the SCSI device. If *InTransferLength* is larger than the SCSI controller can handle, no data will be transferred, *InTransferLength* will be updated to contain the number of bytes that the SCSI controller is able to transfer, and **EFI_BAD_BUFFER_SIZE** will be returned.

OutTransferLength On Input, the size, in bytes of *OutDataBuffer*. On Output, the Number of bytes transferred between SCSI Controller and the SCSI device. If *OutTransferLength* is larger than the SCSI controller can handle, no data will be transferred, *OutTransferLength* will be updated to contain the number of bytes that the SCSI controller is able to transfer, and **EFI_BAD_BUFFER_SIZE** will be returned.

CdbLength The length, in bytes, of the buffer *Cdb*. The standard values are 6, 10, 12, and 16, but other values are possible if a variable length *CDB* is used.

DataDirection The direction of the data transfer. 0 for reads, 1 for writes. A value of 2 is Reserved for Bi-Directional SCSI commands. For example XDREADWRITE. All other values are reserved, and must not be used.

HostAdapterStatus The status of the host adapter specified by *This* when the SCSI Request Packet was executed on the target device. See the possible values listed below. If bit 7 of this field is set, then *HostAdapterStatus* is a vendor defined error code.

TargetStatus The status returned by the device specified by *Target* and *Lun* when the SCSI Request Packet was executed. See the possible values listed below.

SenseDataLength On input, the length in bytes of the *SenseData* buffer. On output, the number of bytes written to the *SenseData* buffer.

```
//
// DataDirection
//
#define EFI_EXT_SCSI_DATA_DIRECTION_READ          0
#define EFI_EXT_SCSI_DATA_DIRECTION_WRITE        1
#define EFI_EXT_SCSI_DATA_DIRECTION_BIDIRECTIONAL 2
//
// HostAdapterStatus
//

#define EFI_EXT_SCSI_STATUS_TARGET_ACA_ACTIVE 0x30
#define EFI_EXT_SCSI_STATUS_TARGET_TASK_ABORTED 0x40
    
```

Description

The [PassThru\(\)](#) function sends the SCSI Request Packet specified by *Packet* to the SCSI device specified by *Target* and *Lun*. If the driver supports nonblocking I/O and *Event* is not **NULL**, then the driver will return immediately after the command is sent to the selected device, and will later signal *Event* when the command has completed.

If the driver supports nonblocking I/O and *Event* is **NULL**, then the driver will send the command to the selected device and block until it is complete.

If the driver does not support nonblocking I/O, then the *Event* parameter is ignored, and the driver will send the command to the selected device and block until it is complete.

If *Packet* is successfully sent to the SCSI device, then **EFI_SUCCESS** is returned.

If *Packet* cannot be sent because there are too many packets already queued up, then **EFI_NOT_READY** is returned. The caller may retry *Packet* at a later time.

If a device error occurs while sending the *Packet*, then **EFI_DEVICE_ERROR** is returned.

If a timeout occurs during the execution of *Packet*, then **EFI_TIMEOUT** is returned.

If a device is not present but the target/LUN address in the packet are valid, then **EFI_TIMEOUT** is returned, and *HostStatus* is set to

EFI_EXT_SCSI_STATUS_HOST_ADAPTER_TIMEOUT_COMMAND.

If *Target* or *Lun* are not in a valid range for the SCSI channel, then **EFI_INVALID_PARAMETER** is returned. If *InDataBuffer*, *OutDataBuffer* or *SenseData* do not meet the alignment requirement specified by the *IoAlign* field of the **EFI_EXT_SCSI_PASS_THRU_MODE** structure, then **EFI_INVALID_PARAMETER** is returned. If any of the other fields of *Packet* are invalid, then **EFI_INVALID_PARAMETER** is returned.

If the data buffer described by *InDataBuffer* and *InTransferLength* is too big to be transferred in a single command, then no data is transferred and **EFI_BAD_BUFFER_SIZE** is

returned. The number of bytes that can be transferred in a single command are returned in *InTransferLength*.

If the data buffer described by *OutDataBuffer* and *OutTransferLength* is too big to be transferred in a single command, then no data is transferred and **EFI_BAD_BUFFER_SIZE** is returned. The number of bytes that can be transferred in a single command are returned in *OutTransferLength*.

If the command described in *Packet* is not supported by the host adapter, then **EFI_UNSUPPORTED** is returned.

If **EFI_SUCCESS**, **EFI_BAD_BUFFER_SIZE**, **EFI_DEVICE_ERROR**, or **EFI_TIMEOUT** is returned, then the caller must examine the status fields in *Packet* in the following precedence order: *HostAdapterStatus* followed by *TargetStatus* followed by *SenseDataLength*, followed by *SenseData*.

If nonblocking I/O is being used, then the status fields in *Packet* will not be valid until the *Event* associated with *Packet* is signaled.

If **EFI_NOT_READY**, **EFI_INVALID_PARAMETER** or **EFI_UNSUPPORTED** is returned, then *Packet* was never sent, so the status fields in *Packet* are not valid. If nonblocking I/O is being used, the *Event* associated with *Packet* will not be signaled.

Note: Some examples of SCSI read commands are READ, INQUIRY, and MODE_SENSE.

Note: Some examples of SCSI write commands are WRITE and MODE_SELECT.

Note: An example of a SCSI non data command is TEST_UNIT_READY.

Status Codes Returned

EFI_SUCCESS	The SCSI Request Packet was sent by the host. For bi-directional commands, <i>InTransferLength</i> bytes were transferred from <i>InDataBuffer</i> . For write and bi-directional commands, <i>OutTransferLength</i> bytes were transferred by <i>OutDataBuffer</i> . See <i>HostAdapterStatus</i> , <i>TargetStatus</i> , <i>SenseDataLength</i> , and <i>SenseData</i> in that order for additional status information.
EFI_BAD_BUFFER_SIZE	The SCSI Request Packet was not executed. The number of bytes that could be transferred is returned in <i>InTransferLength</i> . For write and bi-directional commands, <i>OutTransferLength</i> bytes were transferred by <i>OutDataBuffer</i> . See <i>HostAdapterStatus</i> , <i>TargetStatus</i> , and in that order for additional status information.
EFI_NOT_READY	The SCSI Request Packet could not be sent because there are too many SCSI Request Packets already queued. The caller may retry again later.
EFI_DEVICE_ERROR	A device error occurred while attempting to send the SCSI Request Packet. See <i>HostAdapterStatus</i> , <i>TargetStatus</i> , <i>SenseDataLength</i> , and <i>SenseData</i> in that order for additional status information.

Unified Extensible Firmware Interface Specification

EFI_INVALID_PARAMETER	<i>Target</i> , <i>Lun</i> , or the contents of <i>ScsiRequestPacket</i> are invalid. The SCSI Request Packet was not sent, so no additional status information is available.
EFI_UNSUPPORTED	The command described by the SCSI Request Packet is not supported by the host adapter. This includes the case of Bi-directional SCSI commands not supported by the implementation. The SCSI Request Packet was not sent, so no additional status information is available.
EFI_TIMEOUT	A timeout occurred while waiting for the SCSI Request Packet to execute. See <i>HostAdapterStatus</i> , <i>TargetStatus</i> , <i>SenseDataLength</i> , and <i>SenseData</i> in that order for additional status information.

EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTargetLun()

Summary

Used to retrieve the list of legal Target IDs and LUNs for SCSI devices on a SCSI channel. These can either be the list SCSI devices that are actually present on the SCSI channel, or the list of legal Target IDs and LUNs for the SCSI channel. Regardless, the caller of this function must probe the Target ID and LUN returned to see if a SCSI device is actually present at that location on the SCSI channel.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EXT_SCSI_PASS_THRU_GET_NEXT_TARGET_LUN) (
    IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL  *This,
    IN OUT UINT8                        **Target,
    IN OUT UINT64                       *Lun
);
```

Parameters

<i>This</i>	A pointer to the EFI_EXT_SCSI_PASS_THRU_PROTOCOL instance. Type EFI_EXT_SCSI_PASS_THRU_PROTOCOL is defined in Section 14.7 .
<i>Target</i>	On input, a pointer to a legal Target ID (an array of size TARGET_MAX_BYTES) for a SCSI device present on the SCSI channel. On output, a pointer to the next legal Target ID (an array of TARGET_MAX_BYTES) of a SCSI device on a SCSI channel. An input value of 0xFF 's (all bytes in the array are 0xFF) in the Target array retrieves the first legal Target ID for a SCSI device present on a SCSI channel.
<i>Lun</i>	On input, a pointer to the LUN of a SCSI device present on the SCSI channel. On output, a pointer to the LUN of the next SCSI device ID on a SCSI channel.

Description

The **EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTargetLun()** function retrieves a list of legal Target ID and LUN of a SCSI channel. If on input a *Target* is specified by all **0xFF** in the Target array, then the first legal Target ID and LUN for a SCSI device on a SCSI channel is returned in *Target* and *Lun*, and **EFI_SUCCESS** is returned.

If *Target* and *Lun* is a Target ID and LUN value that was returned on a previous call to **GetNextTargetLun()**, then the next legal Target ID and LUN for a SCSI device on the SCSI channel is returned in *Target* and *Lun*, and **EFI_SUCCESS** is returned.

If *Target array* is not all **0xFF**'s and *Target* and *Lun* were not returned on a previous call to **GetNextTargetLun()**, then **EFI_INVALID_PARAMETER** is returned.

If *Target* and *Lun* are the Target ID and LUN of the last SCSI device on the SCSI channel, then **EFI_NOT_FOUND** is returned.

Status Codes Returned

EFI_SUCCESS	The Target ID and LUN of the next SCSI device on the SCSI channel was returned in <i>Target</i> and <i>Lun</i> .
EFI_NOT_FOUND	There are no more SCSI devices on this SCSI channel.
EFI_INVALID_PARAMETER	<i>Target array</i> is not all 0xFF 's, and <i>Target</i> and <i>Lun</i> were not returned on a previous call to GetNextTargetLun() .

EFI_EXT_SCSI_PASS_THRU_PROTOCOL.BuildDevicePath()

Summary

Used to allocate and build a device path node for a SCSI device on a SCSI channel.

Prototype

```
typedef
    EFI_STATUS
    (EFIAPI *EFI_EXT_SCSI_PASS_THRU_BUILD_DEVICE_PATH) (
        IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL    *This,
        IN UINT8                               *Target,
        IN UINT64                              Lun,
        IN OUT EFI_DEVICE_PATH_PROTOCOL       **DevicePath
    );
```

Parameters

<i>This</i>	A pointer to the EFI_EXT_SCSI_PASS_THRU_PROTOCOL instance. Type EFI_EXT_SCSI_PASS_THRU_PROTOCOL is defined in Section 14.7 .
<i>Target</i>	The Target is an array of size TARGET_MAX_BYTES and it specifies the Target ID of the SCSI device for which a device path node is to be allocated and built. Transport drivers may chose to utilize a subset of this size to suit the representation of targets. For example, a Fibre Channel driver may use only 8 bytes (WWN) in the array to represent a FC target.
<i>Lun</i>	The LUN of the SCSI device for which a device path node is to be allocated and built.
<i>DevicePath</i>	A pointer to a single device path node that describes the SCSI device specified by <i>Target</i> and <i>Lun</i> . This function is responsible for allocating the buffer <i>DevicePath</i> with the boot service AllocatePool () . It is the caller's responsibility to free <i>DevicePath</i> when the caller is finished with <i>DevicePath</i> .

Description

The **EFI_EXT_SCSI_PASS_THRU_PROTOCOL.BuildDevicePath ()** function allocates and builds a single device path node for the SCSI device specified by *Target* and *Lun*. If the SCSI device specified by *Target* and *Lun* are not present on the SCSI channel, then **EFI_NOT_FOUND** is returned. If *DevicePath* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If there are not enough resources to allocate the device path node, then **EFI_OUT_OF_RESOURCES** is returned. Otherwise, *DevicePath* is allocated with the boot service **AllocatePool ()**, the contents of *DevicePath* are initialized to describe the SCSI device specified by *Target* and *Lun*, and **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The device path node that describes the SCSI device specified by <i>Target</i> and <i>Lun</i> was allocated and returned in <i>DevicePath</i> .
EFI_NOT_FOUND	The SCSI devices specified by <i>Target</i> and <i>Lun</i> does not exist on the SCSI channel.
EFI_INVALID_PARAMETER	<i>DevicePath</i> is NULL .
EFI_OUT_OF_RESOURCES	There are not enough resources to allocate DevicePath.

EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetTargetLun()

Summary

Used to translate a device path node to a Target ID and LUN.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_EXT_SCSI_PASS_THRU_GET_TARGET_LUN) (
    IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL *This,
    IN EFI_DEVICE_PATH_PROTOCOL       *DevicePath
    OUT UINT8                          **Target,
    OUT UINT64                         *Lun
);
```

Parameters

<i>This</i>	A pointer to the EFI_EXT_SCSI_PASS_THRU_PROTOCOL instance. Type EFI_EXT_SCSI_PASS_THRU_PROTOCOL is defined in Section 14.7 .
<i>DevicePath</i>	A pointer to the device path node that describes a SCSI device on the SCSI channel.
<i>Target</i>	A pointer to the Target Array which represents the ID of a SCSI device on the SCSI channel.
<i>Lun</i>	A pointer to the LUN of a SCSI device on the SCSI channel.

Description

The **EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetTargetLun()** function determines the Target ID and LUN associated with the SCSI device described by *DevicePath*. If *DevicePath* is a device path node type that the SCSI Pass Thru driver supports, then the SCSI Pass Thru driver will attempt to translate the contents *DevicePath* into a Target ID and LUN. If this translation is successful, then that Target ID and LUN are returned in *Target* and *Lun*, and **EFI_SUCCESS** is returned.

If *DevicePath*, *Target*, or *Lun* are **NULL**, then **EFI_INVALID_PARAMETER** is returned.

If *DevicePath* is not a device path node type that the SCSI Pass Thru driver supports, then **EFI_UNSUPPORTED** is returned.

If *DevicePath* is a device path node type that the SCSI Pass Thru driver supports, but there is not a valid translation from *DevicePath* to a Target ID and LUN, then **EFI_NOT_FOUND** is returned.

Status Codes Returned

EFI_SUCCESS	<i>DevicePath</i> was successfully translated to a Target ID and LUN, and they were returned in Target and Lun.
EFI_INVALID_PARAMETER	<i>DevicePath</i> is NULL .

Unified Extensible Firmware Interface Specification

EFI_INVALID_PARAMETER	<i>Target</i> is NULL
EFI_INVALID_PARAMETER	<i>Lun</i> is NULL
EFI_UNSUPPORTED	This driver does not support the device path node type in <i>DevicePath</i> .
EFI_NOT_FOUND	A valid translation from <i>DevicePath</i> to a Target ID and LUN does not exist.

EFI_EXT_SCSI_PASS_THRU_PROTOCOL.ResetChannel()

Summary

Resets a SCSI channel. This operation resets all the SCSI devices connected to the SCSI channel.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EXT_SCSI_PASS_THRU_RESET_CHANNEL) (
    IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL      *This
);
```

Parameters

This A pointer to the **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** instance. Type **EFI_EXT_SCSI_PASS_THRU_PROTOCOL** is defined in [Section 14.7](#).

Description

The **EFI_EXT_SCSI_PASS_THRU_PROTOCOL.ResetChannel()** function resets a SCSI channel. This operation resets all the SCSI devices connected to the SCSI channel. If this SCSI channel does not support a reset operation, then **EFI_UNSUPPORTED** is returned.

If a device error occurs while executing that channel reset operation, then **EFI_DEVICE_ERROR** is returned.

If a timeout occurs during the execution of the channel reset operation, then **EFI_TIMEOUT** is returned. If the channel reset operation is completed, then **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The SCSI channel was reset.
EFI_UNSUPPORTED	The SCSI channel does not support a channel reset operation.
EFI_DEVICE_ERROR	A device error occurred while attempting to reset the SCSI channel.
EFI_TIMEOUT	A timeout occurred while attempting to reset the SCSI channel.

EFI_EXT_SCSI_PASS_THRU_PROTOCOL.ResetTargetLun()

Summary

Resets a SCSI logical unit that is connected to a SCSI channel.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_EXT_SCSI_PASS_THRU_RESET_TARGET_LUN) (
    IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL    *This,
    IN UINT8                               *Target,
    IN UINT64                              Lun
);
```

Parameters

<i>This</i>	A pointer to the EFI_EXT_SCSI_PASS_THRU_PROTOCOL instance. Type EFI_EXT_SCSI_PASS_THRU_PROTOCOL is defined in Section 14.7 .
<i>Target</i>	The Target is an array of size TARGET_MAX_BYTE and it represents the target port ID of the SCSI device containing the SCSI logical unit to reset. Transport drivers may chose to utilize a subset of this array to suit the representation of their targets. For example a Fibre Channel driver may use only 8 bytes in the array (WWN) to represent a FC target.
<i>Lun</i>	The LUN of the SCSI device to reset.

Description

The **EFI_EXT_SCSI_PASS_THRU_PROTOCOL.ResetTargetLun()** function resets the SCSI logical unit specified by *Target* and *Lun*. If this SCSI channel does not support a target reset operation, then **EFI_UNSUPPORTED** is returned.

If *Target* or *Lun* are not in a valid range for this SCSI channel, then **EFI_INVALID_PARAMETER** is returned.

If a device error occurs while executing that logical unit reset operation, then **EFI_DEVICE_ERROR** is returned.

If a timeout occurs during the execution of the logical unit reset operation, then **EFI_TIMEOUT** is returned.

If the logical unit reset operation is completed, then **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The SCSI device specified by <i>Target</i> and <i>Lun</i> was reset
EFI_UNSUPPORTED	The SCSI channel does not support a target reset operation.
EFI_INVALID_PARAMETER	<i>Target</i> or <i>Lun</i> are invalid.

EFI_DEVICE_ERROR	A device error occurred while attempting to reset the SCSI device specified by <i>Target</i> and <i>Lun</i> .
EFI_TIMEOUT	A timeout occurred while attempting to reset the SCSI device specified by <i>Target</i> and <i>Lun</i> .

EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTarget()

Summary

Used to retrieve the list of legal Target IDs for SCSI devices on a SCSI channel. These can either be the list SCSI devices that are actually present on the SCSI channel, or the list of legal Target IDs for the SCSI channel. Regardless, the caller of this function must probe the Target ID returned to see if a SCSI device is actually present at that location on the SCSI channel.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EXT_SCSI_PASS_THRU_GET_NEXT_TARGET) (
    IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL *This,
    IN OUT UINT8                        **Target,
);
```

Parameters

<i>This</i>	A pointer to the EFI_EXT_SCSI_PASS_THRU_PROTOCOL instance. Type EFI_EXT_SCSI_PASS_THRU_PROTOCOL is defined in Section 14.7 .
<i>Target</i>	On input, a pointer to the Target ID (an array of size TARGET_MAX_BYTES) of a SCSI device present on the SCSI channel. On output, a pointer to the Target ID (an array of TARGET_MAX_BYTES) of the next SCSI device present on a SCSI channel. An input value of 0xFF 's (all bytes in the array are 0xFF) in the Target array retrieves the Target ID of the first SCSI device present on a SCSI channel.

Description

The **EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTarget()** function retrieves the Target ID of a SCSI device present on a SCSI channel. If on input a *Target* is specified by all 0xF in the Target array, then the Target ID of the first SCSI device is returned in *Target* and **EFI_SUCCESS** is returned.

If *Target* is a Target ID value that was returned on a previous call to **GetNextTarget()**, then the Target ID of the next SCSI device on the SCSI channel is returned in *Target*, and **EFI_SUCCESS** is returned.

If *Target* array is not all **0xFF**'s and *Target* were not returned on a previous call to **GetNextTarget()**, then **EFI_INVALID_PARAMETER** is returned.

If *Target* is the Target ID of the last SCSI device on the SCSI channel, then **EFI_NOT_FOUND** is returned.

Status Codes Returned

EFI_SUCCESS	The Target ID of the next SCSI device on the SCSI channel was returned in <i>Target</i> .
EFI_NOT_FOUND	There are no more SCSI devices on this SCSI channel.
EFI_INVALID_PARAMETER	<i>Target array</i> is not all 0xFF 's, and <i>Target</i> were not returned on a previous call to GetNextTarget () .

15

Protocols — iSCSI Boot

15.1 Overview

The iSCSI protocol defines a transport for SCSI data over TCP/IP. It also provides an interoperable solution that takes advantage of existing internet infrastructure, management facilities, and addresses distance limitations. The iSCSI protocol specification was developed by the Internet Engineering Task Force (IETF) and is SCSI Architecture Model-2 (SAM-2) compliant. iSCSI encapsulates block-oriented SCSI commands into iSCSI Protocol Data Units (PDU) that traverse the network over TCP/IP. iSCSI defines a Session, the initiator and target nexus (I-T nexus), which could be a bundle of one or more TCP connections.

Similar to other existing mass storage protocols like Fibre Channel and parallel SCSI, boot over iSCSI is an important functionality. This document will attempt to capture the various cases for iSCSI boot and common up with generic EFI protocol changes to address them.

15.1.1 iSCSI UEFI Driver Layering

iSCSI UEFI Drivers may exist in two different forms:

- iSCSI UEFI Driver on a NIC:

The driver will be layered on top of the networking layers. It will use the DHCP, IP, and TCP and packet level interface protocols of the UEFI networking stack. The driver will use an iSCSI software initiator.

- iSCSI UEFI Driver on a Host Bus Adapter (HBA) that may use an offloading engine such as TOE (or any other TCP offload card):

The driver will be layered on top of the TOE TCP interfaces. It will use the DHCP, IP, TCP protocols of the TOE. The driver will present itself as a SCSI device driver using interfaces such as **EFI_EXT_SCSI_PASS_THRU_PROTOCOL**.

To help in detecting iSCSI UEFI Drivers and their capabilities, the iSCSI UEFI driver handle must include an instance of the **EFI_ADAPTER_INFORMATION_PROTOCOL** with a **EFI_ADAPTER_INFO_NETWORK_BOOT** structure.

15.2 EFI iSCSI Initiator Name Protocol

This protocol sets and obtains the iSCSI Initiator Name. The iSCSI Initiator Name protocol builds a default iSCSI name. The iSCSI name configures using the programming interfaces defined below. Successive configuration of the iSCSI initiator name overwrites the previously existing name. Once overwritten, the previous name will not be retrievable. Setting an iSCSI name string that is zero length is illegal. The maximum size of the iSCSI Initiator Name is 224 bytes (including the NULL terminator).

EFI_ISCSI_INITIATOR_NAME_PROTOCOL

Summary

iSCSI Initiator Name Protocol for setting and obtaining the iSCSI Initiator Name.

GUID

```
#define EFI_ISCSI_INITIATOR_NAME_PROTOCOL_GUID \
    {0x59324945, 0xec44, 0x4c0d, \
     {0xb1, 0xcd, 0x9d, 0xb1, 0x39, 0xdf, 0x07, 0x0c}}
```

Protocol Interface Structure

```
typedef struct _EFI_ISCSI_INITIATOR_NAME_PROTOCOL {
    EFI_ISCSI_INITIATOR_NAME_GET  Get;
    EFI_ISCSI_INITIATOR_NAME_SET  Set;
} EFI_ISCSI_INITIATOR_NAME_PROTOCOL;
```

Parameters

<i>Get</i>	Used to retrieve the iSCSI Initiator Name.
<i>Set</i>	Used to set the iSCSI Initiator Name.

Description

The `EFI_ISCSI_INIT_NAME_PROTOCOL` provides the ability to get and set the iSCSI Initiator Name.

EFI_ISCSI_INITIATOR_NAME_PROTOCOL. Get()

Summary

Retrieves the current set value of iSCSI Initiator Name.

Prototype

```
typedef EFI_STATUS
(EFI_API *EFI_ISCSI_INITIATOR_NAME_GET) {
    IN     EFI_ISCSI_INITIATOR_NAME_PROTOCOL *This
    IN OUT UINTN                             *BufferSize
    OUT    VOID                               *Buffer
}
```

Parameters

<i>This</i>	Pointer to the EFI_ISCSI_INITIATOR_NAME_PROTOCOL instance.
<i>BufferSize</i>	Size of the buffer in bytes pointed to by Buffer / Actual size of the variable data buffer.
<i>Buffer</i>	Pointer to the buffer for data to be read. The data is a null-terminated UTF-8 encoded string. The maximum length is 223 characters, including the null-terminator.

Description

This function will retrieve the iSCSI Initiator Name from Non-volatile memory.

Status Codes Returned

EFI_SUCCESS	Data was successfully retrieved into the provided buffer and the <i>BufferSize</i> was sufficient to handle the iSCSI initiator name
EFI_BUFFER_TOO_SMALL	<i>BufferSize</i> is too small for the result. <i>BufferSize</i> will be updated with the size required to complete the request. <i>Buffer</i> will not be affected.
EFI_INVALID_PARAMETER	<i>BufferSize</i> is NULL . <i>BufferSize</i> and <i>Buffer</i> will not be affected.
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL . <i>BufferSize</i> and <i>Buffer</i> will not be affected.
EFI_DEVICE_ERROR	The iSCSI initiator name could not be retrieved due to a hardware error.

EFI_ISCSI_INITIATOR_NAME_PROTOCOL.Set()

Summary

Sets the iSCSI Initiator Name.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_ISCSI_INITIATOR_NAME_SET) {
    IN     EFI_ISCSI_INITIATOR_NAME_PROTOCOL  *This
    IN OUT UINTN                               *BufferSize
    IN     VOID                               *Buffer
}
```

Parameters

<i>This</i>	Pointer to the EFI_ISCSI_INITIATOR_NAME_PROTOCOL instance
<i>BufferSize</i>	Size of the buffer in bytes pointed to by Buffer.
<i>Buffer</i>	Pointer to the buffer for data to be written. The data is a null-terminated UTF-8 encoded string. The maximum length is 223 characters, including the null-terminator.

Description

This function will set the iSCSI Initiator Name into Non-volatile memory.

Status Codes Returned

EFI_SUCCESS	Data was successfully stored by the protocol
EFI_UNSUPPORTED	Platform policies do not allow for data to be written
EFI_INVALID_PARAMETER	<i>BufferSize</i> exceeds the maximum allowed limit. <i>BufferSize</i> will be updated with the maximum size required to complete the request.
EFI_INVALID_PARAMETER	<i>Buffersize</i> is NULL . <i>BufferSize</i> and <i>Buffer</i> will not be affected
EFI_INVALID_PARAMETER	<i>Buffer</i> is NULL . <i>BufferSize</i> and <i>Buffer</i> will not be affected.
EFI_DEVICE_ERROR	The data could not be stored due to a hardware error.
EFI_OUT_OF_RESOURCES	Not enough storage is available to hold the data
EFI_PROTOCOL_ERROR	Input iSCSI initiator name does not adhere to RFC 3720 (and other related protocols)

16.1 USB2 Host Controller Protocol

[Section 16.1](#) and [Section 16.1.1](#) describe the USB2 Host Controller Protocol. This protocol provides an I/O abstraction for a USB2 Host Controller. The USB2 Host Controller is a hardware component that interfaces to a Universal Serial Bus (USB). It moves data between system memory and devices on the USB by processing data structures and generating transactions on the USB. This protocol is used by a USB Bus Driver to perform all data transaction over the Universal Serial Bus. It also provides services to manage the USB root hub that is integrated into the USB Host Controller. USB device drivers do not use this protocol directly. Instead, they use the I/O abstraction produced by the USB Bus Driver. This protocol should only be used by drivers that require direct access to the USB bus.

16.1.1 USB Host Controller Protocol Overview

The USB Host Controller Protocol is used by code, typically USB bus drivers, running in the EFI boot services environment, to perform data transactions over a USB bus. In addition, it provides an abstraction for the root hub of the USB bus.

The interfaces provided in the [EFI_USB2_HC_PROTOCOL](#) are used to manage data transactions on a USB bus. It also provides control methods for the USB root hub. The [EFI_USB2_HC_PROTOCOL](#) is designed to support both USB 1.1 and USB 2.0 – compliant host controllers.

The [EFI_USB2_HC_PROTOCOL](#) abstracts basic functionality that is designed to operate with the EHCI, UHCI and OHCI standards. By using this protocol, a single USB bus driver can be implemented without knowing if the underlying USB host controller conforms to the XHCI, EHCI, OHCI or the UHCI standards.

Each instance of the [EFI_USB2_HC_PROTOCOL](#) corresponds to a USB host controller in a platform. The protocol is attached to the device handle of a USB host controller that is created by a device driver for the USB host controller's parent bus type. For example, a USB host controller that is implemented as a PCI device would require a PCI device driver to produce an instance of the [EFI_USB2_HC_PROTOCOL](#).

EFI_USB2_HC_PROTOCOL

Summary

Provides basic USB host controller management, basic data transactions over USB bus, and USB root hub access.

GUID

```
#define EFI_USB2_HC_PROTOCOL_GUID \
    { 0x3e745226, 0x9818, 0x45b6, \
      0xa2, 0xac, 0xd7, 0xcd, 0x0e, 0x8b, 0xa2, 0xbc }
```

Protocol Interface Structure

```
typedef struct _EFI_USB2_HC_PROTOCOL {
    EFI_USB2_HC_PROTOCOL_GET_CAPABILITY    GetCapability;
    EFI_USB2_HC_PROTOCOL_RESET            Reset;
    EFI_USB2_HC_PROTOCOL_GET_STATE        GetState;
    EFI_USB2_HC_PROTOCOL_SET_STATE        SetState;
    EFI_USB2_HC_PROTOCOL_CONTROL_TRANSFER ControlTransfer;
    EFI_USB2_HC_PROTOCOL_BULK_TRANSFER    BulkTransfer;
    EFI_USB2_HC_PROTOCOL_ASYNC_INTERRUPT_TRANSFER AsyncInterruptTransfer;
    EFI_USB2_HC_PROTOCOL_SYNC_INTERRUPT_TRANSFER SyncInterruptTransfer;
    EFI_USB2_HC_PROTOCOL_ISOCHRONOUS_TRANSFER IsochronousTransfer;
    EFI_USB2_HC_PROTOCOL_ASYNC_ISOCHRONOUS_TRANSFER AsyncIsochronousTransfer;
    EFI_USB2_HC_PROTOCOL_GET_ROOTHUB_PORT_STATUS GetRootHubPortStatus;
    EFI_USB2_HC_PROTOCOL_SET_ROOTHUB_PORT_FEATURE SetRootHubPortFeature;
    EFI_USB2_HC_PROTOCOL_CLEAR_ROOTHUB_PORT_FEATURE ClearRootHubPortFeature;

    UINT16    MajorRevision;
    UINT16    MinorRevision;
} EFI_USB2_HC_PROTOCOL;
```

Parameters

<i>GetCapability</i>	Retrieves the capabilities of the USB host controller. See the GetCapability() function description.
<i>Reset</i>	Software reset of USB. See the Reset() function description.
<i>GetState</i>	Retrieves the current state of the USB host controller. See the GetState() function description.
<i>SetState</i>	Sets the USB host controller to a specific state. See the SetState() function description.
<i>ControlTransfer</i>	Submits a control transfer to a target USB device. See the ControlTransfer() function description.
<i>BulkTransfer</i>	Submits a bulk transfer to a bulk endpoint of a USB device. See the BulkTransfer() function description.

AsyncInterruptTransfer

Submits an asynchronous interrupt transfer to an interrupt endpoint of a USB device. See the [AsyncInterruptTransfer \(\)](#) function description.

SyncInterruptTransfer

Submits a synchronous interrupt transfer to an interrupt endpoint of a USB device. See the [SyncInterruptTransfer \(\)](#) function description.

IsochronousTransfer

Submits isochronous transfer to an isochronous endpoint of a USB device. See the [IsochronousTransfer \(\)](#) function description.

AsyncIsochronousTransfer

Submits nonblocking USB isochronous transfer. See the [AsyncIsochronousTransfer \(\)](#) function description.

GetRootHubPortStatus

Retrieves the status of the specified root hub port. See the [GetRootHubPortStatus \(\)](#) function description.

SetRootHubPortFeature

Sets the feature for the specified root hub port. See the [SetRootHubPortFeature \(\)](#) function description.

ClearRootHubPortFeature

Clears the feature for the specified root hub port. See the [ClearRootHubPortFeature \(\)](#) function description.

MajorRevision

The major revision number of the USB host controller. The revision information indicates the release of the Universal Serial Bus Specification with which the host controller is compliant.

MinorRevision

The minor revision number of the USB host controller. The revision information indicates the release of the Universal Serial Bus Specification with which the host controller is compliant.

Description

The **EFI_USB2_HC_PROTOCOL** provides USB host controller management, basic data transactions over a USB bus, and USB root hub access. A device driver that wishes to manage a USB bus in a system retrieves the **EFI_USB2_HC_PROTOCOL** instance that is associated with the USB bus to be managed. A device handle for a USB host controller will minimally contain an [EFI_DEVICE_PATH_PROTOCOL](#) instance, and an **EFI_USB2_HC_PROTOCOL** instance.

EFI_USB2_HC_PROTOCOL.GetCapability()

Summary

Retrieves the Host Controller capabilities.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_GET_CAPABILITY) (
    IN  EFI_USB2_HC_PROTOCOL  *This,
    OUT UINT8                 *MaxSpeed,
    OUT UINT8                 *PortNumber,
    OUT UINT8                 *Is64BitCapable
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>MaxSpeed</i>	Host controller data transfer speed; see “Related Definitions” below for a list of supported transfer speed values.
<i>PortNumber</i>	Number of the root hub ports.
<i>Is64BitCapable</i>	TRUE if controller supports 64-bit memory addressing, FALSE otherwise.

Related Definitions

```
#define EFI_USB_SPEED_FULL  0x0000
#define EFI_USB_SPEED_LOW   0x0001
#define EFI_USB_SPEED_HIGH  0x0002
#define EFI_USB_SPEED_SUPER 0x0003
```

EFI_USB_SPEED_LOW	Low speed USB device; data bandwidth is up to 1.5 Mb/s. Supported by USB 1.1 OHCI and UHCI host controllers.
EFI_USB_SPEED_FULL	Full speed USB device; data bandwidth is up to 12 Mb/s. Supported by USB 1.1 OHCI and UHCI host controllers.
EFI_USB_SPEED_HIGH	High speed USB device; data bandwidth is up to 480 Mb/s. Supported by USB 2.0 EHCI host controllers.
EFI_USB_SPEED_SUPER	Super speed USB device; data bandwidth is up to 4.8Gbs. Supported by USB 3.0 XHCI host controllers.

Description

This function is used to retrieve the host controller capabilities. *MaxSpeed* indicates the maximum data transfer speed the controller is capable of; this information is needed for the subsequent transfers. *PortNumber* is the number of root hub ports, it is required by the USB bus driver to perform bus enumeration. *Is64BitCapable* indicates that controller is capable of 64-bit memory access so that the host controller software can use memory blocks above 4 GiB for the data transfers.

Status Codes Returned

EFI_SUCCESS	The host controller capabilities were retrieved successfully.
EFI_INVALID_PARAMETER	MaxSpeed or PortNumber or Is64BitCapable is NULL .
EFI_DEVICE_ERROR	An error was encountered while attempting to retrieve the capabilities.

EFI_USB2_HC_PROTOCOL.Reset()

Summary

Provides software reset for the USB host controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_RESET) (
    IN  EFI_USB2_HC_PROTOCOL    *This,
    IN  UINT16                  Attributes
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>Attributes</i>	A bit mask of the reset operation to perform. See “Related Definitions” below for a list of the supported bit mask values.

Related Definitions

```
#define EFI_USB_HC_RESET_GLOBAL          0x0001
#define EFI_USB_HC_RESET_HOST_CONTROLLER 0x0002
#define EFI_USB_HC_RESET_GLOBAL_WITH_DEBUG 0x0004
#define EFI_USB_HC_RESET_HOST_WITH_DEBUG 0x0008
```

EFI_USB_HC_RESET_GLOBAL

If this bit is set, a global reset signal will be sent to the USB bus. This resets all of the USB bus logic, including the USB host controller hardware and all the devices attached on the USB bus.

EFI_USB_HC_RESET_HOST_CONTROLLER

If this bit is set, the USB host controller hardware will be reset. No reset signal will be sent to the USB bus.

EFI_USB_HC_RESET_GLOBAL_WITH_DEBUG

If this bit is set, then a global reset signal will be sent to the USB bus. This resets all of the USB bus logic, including the USB host controller and all of the devices attached on the USB bus. If this is an XHCI or EHCI controller and the debug port has been configured, then this will still reset the host controller.

EFI_USB_HC_RESET_HOST_WITH_DEBUG

If this bit is set, the USB host controller hardware will be reset. If this is an XHCI or EHCI controller and the debug port has been configured, then this will still reset the host controller.

Description

This function provides a software mechanism to reset a USB host controller. The type of reset is specified by the *Attributes* parameter. If the type of reset specified by *Attributes* is not valid, then **EFI_INVALID_PARAMETER** is returned. If the reset operation is completed, then **EFI_SUCCESS** is returned. If the type of reset specified by *Attributes* is not currently supported by the host controller hardware, **EFI_UNSUPPORTED** is returned. If a device error occurs during the reset operation, then **EFI_DEVICE_ERROR** is returned.

Note: For XHCI or EHCI controllers, the **EFI_USB_HC_RESET_GLOBAL** and **EFI_USB_HC_RESET_HOST_CONTROLLER** types of reset do not actually reset the bus if the debug port has been configured. In these cases, the function will return **EFI_ACCESS_DENIED**.

Status Codes Returned

EFI_SUCCESS	The reset operation succeeded.
EFI_INVALID_PARAMETER	<i>Attributes</i> is not valid.
EFI_UNSUPPORTED	The type of reset specified by <i>Attributes</i> is not currently supported by the host controller hardware.
EFI_ACCESS_DENIED	Reset operation is rejected due to the debug port being configured and active; only EFI_USB_HC_RESET_GLOBAL_WITH_DEBUG or EFI_USB_HC_RESET_HOST_WITH_DEBUG reset <i>Attributes</i> can be used to perform reset operation for this host controller.
EFI_DEVICE_ERROR	An error was encountered while attempting to perform the reset operation.

EFI_USB2_HC_PROTOCOL.GetState()

Summary

Retrieves current state of the USB host controller.

Prototype

```

typedef
EFI_STATUS
(EFI_API *EFI_USB2_HC_PROTOCOL_GET_STATE) (
    IN  EFI_USB2_HC_PROTOCOL  *This,
    OUT EFI_USB_HC_STATE      *State
);

```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>State</i>	A pointer to the EFI_USB_HC_STATE data structure that indicates current state of the USB host controller. Type EFI_USB_HC_STATE is defined in “Related Definitions.”

Related Definitions

```

typedef enum {
    EfiUsbHcStateHalt,
    EfiUsbHcStateOperational,
    EfiUsbHcStateSuspend,
    EfiUsbHcStateMaximum
} EFI_USB_HC_STATE;

```

EfiUsbHcStateHalt

The host controller is in halt state. No USB transactions can occur while in this state. The host controller can enter this state for three reasons:

- After host controller hardware reset.
- Explicitly set by software.
- Triggered by a fatal error such as consistency check failure.

EfiUsbHcStateOperational

The host controller is in an operational state. When in this state, the host controller can execute bus traffic. This state must be explicitly set to enable the USB bus traffic.

EfiUsbHcStateSuspend

The host controller is in the suspend state. No USB transactions can occur while in this state. The host controller enters this state for the following reasons:

- Explicitly set by software.
- Triggered when there is no bus traffic for 3 microseconds.

Description

This function is used to retrieve the USB host controller’s current state. The USB Host Controller Protocol publishes three states for USB host controller, as defined in “Related Definitions” below. If *State* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If a device error occurs while attempting to retrieve the USB host controllers current state, then **EFI_DEVICE_ERROR** is returned. Otherwise, the USB host controller’s current state is returned in *State*, and **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The state information of the host controller was returned in <i>State</i> .
EFI_INVALID_PARAMETER	State is NULL .
EFI_DEVICE_ERROR	An error was encountered while attempting to retrieve the host controller’s current state.

EFI_USB2_HC_PROTOCOL.SetState()

Summary

Sets the USB host controller to a specific state.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_SET_STATE) (
    IN EFI_USB2_HC_PROTOCOL    *This,
    IN EFI_USB_HC_STATE        State
);
```

Parameters

This A pointer to the [EFI_USB2_HC_PROTOCOL](#) instance. Type [EFI_USB2_HC_PROTOCOL](#) is defined in [Section 16.1](#).

State Indicates the state of the host controller that will be set. See the definition and description of the type [EFI_USB_HC_STATE](#) in the [GetState\(\)](#) function description.

Description

This function is used to explicitly set a USB host controller’s state. There are three states defined for the USB host controller. These are the halt state, the operational state and the suspend state.

[Figure 52](#) illustrates the possible state transitions:

OM13170

Figure 52. Software Triggered State Transitions of a USB Host Controller

If the state specified by *State* is not valid, then **EFI_INVALID_PARAMETER** is returned. If a device error occurs while attempting to place the USB host controller into the state specified by *State*, then **EFI_DEVICE_ERROR** is returned. If the USB host controller is successfully placed in the state specified by *State*, then **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The USB host controller was successfully placed in the state specified by <i>State</i> .
-------------	--

EFI_INVALID_PARAMETER	<i>State</i> is invalid.
EFI_DEVICE_ERROR	Failed to set the state specified by <i>State</i> due to device error.

EFI_USB2_HC_PROTOCOL.ControlTransfer()

Summary

Submits control transfer to a target USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_CONTROL_TRANSFER) (
    IN      EFI_USB2_HC_PROTOCOL           *This,
    IN      UINT8                          DeviceAddress,
    IN      UINT8                          DeviceSpeed,
    IN      UINTN                          MaximumPacketLength,
    IN      EFI_USB_DEVICE_REQUEST         *Request,
    IN      EFI_USB_DATA_DIRECTION         TransferDirection,
    IN OUT VOID                            *Data          OPTIONAL,
    IN OUT UINTN                          *DataLength    OPTIONAL,
    IN      UINTN                          TimeOut,
    IN      EFI_USB2_HC_TRANSACTION_TRANSLATOR *Translator,
    OUT     UINT32                          *TransferResult
);
```

Related Definitions

```
typedef struct {
    UINT8    TranslatorHubAddress,
    UINT8    TranslatorPortNumber
} EFI_USB2_HC_TRANSACTION_TRANSLATOR;
```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>DeviceAddress</i>	Represents the address of the target device on the USB, which is assigned during USB enumeration.
<i>DeviceSpeed</i>	Indicates device speed. See “Related Definitions” in GetCapability() for a list of the supported values.
<i>MaximumPacketLength</i>	Indicates the maximum packet size that the default control transfer endpoint is capable of sending or receiving.
<i>Request</i>	A pointer to the USB device request that will be sent to the USB device. Refer to UsbControlTransfer() (Section 16.2.4) for the definition of this function type.
<i>TransferDirection</i>	Specifies the data direction for the transfer. There are three values available, EfiUsbDataIn , EfiUsbDataOut and EfiUsbNoData . Refer to UsbControlTransfer() (Section 16.2.4) for the definition of this function type.

<i>Data</i>	A pointer to the buffer of data that will be transmitted to USB device or received from USB device.
<i>DataLength</i>	On input, indicates the size, in bytes, of the data buffer specified by <i>Data</i> . On output, indicates the amount of data actually transferred.
<i>Translator</i>	A pointer to the transaction translator data. See “Description” for the detailed information of this data structure.
<i>TimeOut</i>	Indicates the maximum time, in milliseconds, which the transfer is allowed to complete.
<i>TransferResult</i>	A pointer to the detailed result information generated by this control transfer. Refer to UsbControlTransfer() (Section 16.2.4) for transfer result types (EFI_USB_ERR_x).

Description

This function is used to submit a control transfer to a target USB device specified by *DeviceAddress*. Control transfers are intended to support configuration/command/status type communication flows between host and USB device.

There are three control transfer types according to the data phase. If the *TransferDirection* parameter is **EfiUsbNoData**, *Data* is **NULL**, and *DataLength* is 0, then no data phase is present in the control transfer. If the *TransferDirection* parameter is **EfiUsbDataOut**, then *Data* specifies the data to be transmitted to the device, and *DataLength* specifies the number of bytes to transfer to the device. In this case, there is an OUT DATA stage followed by a SETUP stage. If the *TransferDirection* parameter is **EfiUsbDataIn**, then *Data* specifies the data to be received from the device, and *DataLength* specifies the number of bytes to receive from the device. In this case there is an IN DATA stage followed by a SETUP stage.

Translator is necessary to perform split transactions on low-speed or full-speed devices connected to a high-speed hub. Such transaction require the device connection information: device address and the port number of the hub that device is connected to. This information is passed through the fields of **EFI_USB2_HC_TRANSACTION_TRANSLATOR** structure. See “Related Definitions” for the structure field names. Translator is passed as **NULL** for the USB1.1 host controllers transfers or when the transfer is requested for high-speed device connected to USB2.0 controller.

If the control transfer has completed successfully, then **EFI_SUCCESS** is returned. If the transfer cannot be completed within the timeout specified by *TimeOut*, then **EFI_TIMEOUT** is returned. If an error other than timeout occurs during the USB transfer, then **EFI_DEVICE_ERROR** is returned and the detailed error code will be returned in the *TransferResult* parameter.

EFI_INVALID_PARAMETER is returned if one of the following conditions is satisfied:

- *TransferDirection* is invalid.
- *TransferDirection*, *Data*, and *DataLength* do not match one of the three control transfer types described above.
- *Request* pointer is **NULL**.
- *MaximumPacketLength* is not valid. If *DeviceSpeed* is **EFI_USB_SPEED_LOW**, then *MaximumPacketLength* must be 8. If *DeviceSpeed* is **EFI_USB_SPEED_FULL** or

EFI_USB_SPEED_HIGH, then *MaximumPacketLength* must be 8, 16, 32, or 64. If *DeviceSpeed* is **EFI_USB_SPEED_SUPER**, then *MaximumPacketLength* must be 512.

- *TransferResult* pointer is **NULL**.
- *Translator* is **NULL** while the requested transfer requires split transaction. The conditions of the split transactions are described above in “Description” section.

Status Codes Returned

EFI_SUCCESS	The control transfer was completed successfully.
EFI_OUT_OF_RESOURCES	The control transfer could not be completed due to a lack of resources.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in “Description” above.
EFI_TIMEOUT	The control transfer failed due to timeout.
EFI_DEVICE_ERROR	The control transfer failed due to host controller or device error. Caller should check <i>TransferResult</i> for detailed error information.

EFI_USB2_HC_PROTOCOL.BulkTransfer()

Summary

Submits bulk transfer to a bulk endpoint of a USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_BULK_TRANSFER) (
    IN      EFI_USB2_HC_PROTOCOL *This,
    IN      UINT8                DeviceAddress,
    IN      UINT8                EndPointAddress,
    IN      UINT8                DeviceSpeed,
    IN      UINTN                MaximumPacketLength,
    IN      UINT8                DataBuffersNumber,
    IN OUT VOID                  *Data[EFI_USB_MAX_BULK_BUFFER_NUM],
    IN OUT UINTN                 *DataLength,
    IN OUT UINT8                 *DataToggle,
    IN      UINTN                TimeOut,
    IN      EFI_USB2_HC_TRANSACTION_TRANSLATOR *Translator,
    OUT     UINT32                *TransferResult
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>DeviceAddress</i>	Represents the address of the target device on the USB, which is assigned during USB enumeration.
<i>EndPointAddress</i>	The combination of an endpoint number and an endpoint direction of the target USB device. Each endpoint address supports data transfer in one direction except the control endpoint (whose default endpoint address is 0). It is the caller's responsibility to make sure that the <i>EndPointAddress</i> represents a bulk endpoint.
<i>DeviceSpeed</i>	Indicates device speed. The supported values are EFI_USB_SPEED_FULL , EFI_USB_SPEED_HIGH or EFI_USB_SPEED_SUPER..
<i>MaximumPacketLength</i>	Indicates the maximum packet size the target endpoint is capable of sending or receiving.
<i>DataBuffersNumber</i>	Number of data buffers prepared for the transfer.
<i>Data</i>	Array of pointers to the buffers of data that will be transmitted to USB device or received from USB device.

<i>DataLength</i>	When input, indicates the size, in bytes, of the data buffers specified by <i>Data</i> . When output, indicates the actually transferred data size.
<i>DataToggle</i>	A pointer to the data toggle value. On input, it indicates the initial data toggle value the bulk transfer should adopt; on output, it is updated to indicate the data toggle value of the subsequent bulk transfer.
<i>Translator</i>	A pointer to the transaction translator data. See <code>ControlTransfer()</code> “Description” for the detailed information of this data structure.
<i>TimeOut</i>	Indicates the maximum time, in milliseconds, which the transfer is allowed to complete.
<i>TransferResult</i>	A pointer to the detailed result information of the bulk transfer. Refer to <code>UsbControlTransfer()</code> (Section 16.2.4) for transfer result types (<code>EFI_USB_ERR_x</code>).

Description

This function is used to submit bulk transfer to a target endpoint of a USB device. The target endpoint is specified by *DeviceAddress* and *EndpointAddress*. Bulk transfers are designed to support devices that need to communicate relatively large amounts of data at highly variable times where the transfer can use any available bandwidth. Bulk transfers can be used only by full-speed and high-speed devices.

High-speed bulk transfers can be performed using multiple data buffers. The number of buffers that are actually prepared for the transfer is specified by *DataBuffersNumber*. For full-speed bulk transfers this value is ignored.

Data represents a list of pointers to the data buffers. For full-speed bulk transfers only the data pointed by *Data[0]* shall be used. For high-speed transfers depending on *DataLength* there several data buffers can be used. The total number of buffers must not exceed `EFI_USB_MAX_BULK_BUFFER_NUM`. See “Related Definitions” for the `EFI_USB_MAX_BULK_BUFFER_NUM` value.

The data transfer direction is determined by the endpoint direction that is encoded in the *EndPointAddress* parameter. Refer to *USB Specification, Revision 2.0* on the Endpoint Address encoding.

The *DataToggle* parameter is used to track target endpoint’s data sequence toggle bits. The USB provides a mechanism to guarantee data packet synchronization between data transmitter and receiver across multiple transactions. The data packet synchronization is achieved with the data sequence toggle bits and the DATA0/DATA1 PIDs. A bulk endpoint’s toggle sequence is initialized to DATA0 when the endpoint experiences a configuration event. It toggles between DATA0 and DATA1 in each successive data transfer. It is host’s responsibility to track the bulk endpoint’s data toggle sequence and set the correct value for each data packet. The input *DataToggle* value points to the data toggle value for the first data packet of this bulk transfer; the output *DataToggle* value points to the data toggle value for the last successfully transferred data packet of this bulk transfer. The caller should record the data toggle value for use in subsequent bulk transfers to the same endpoint.

If the bulk transfer is successful, then `EFI_SUCCESS` is returned. If USB transfer cannot be completed within the timeout specified by *Timeout*, then `EFI_TIMEOUT` is returned. If an error

other than timeout occurs during the USB transfer, then **EFI_DEVICE_ERROR** is returned and the detailed status code is returned in *TransferResult*.

EFI_INVALID_PARAMETER is returned if one of the following conditions is satisfied:

- *Data* is **NULL**.
- *DataLength* is 0.
- *DeviceSpeed* is not valid; the legal values are **EFI_USB_SPEED_FULL**, **EFI_USB_SPEED_HIGH**, or **EFI_USB_SPEED_SUPER**.
- *MaximumPacketLength* is not valid. The legal value of this parameter is 64 or less for full-speed, 512 or less for high-speed, and 1024 or less for super-speed transactions.
- *DataToggle* points to a value other than 0 and 1.
- *TransferResult* is **NULL**.

Status Codes Returned

EFI_SUCCESS	The bulk transfer was completed successfully.
EFI_OUT_OF_RESOURCES	The bulk transfer could not be submitted due to lack of resource.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in “Description” above.
EFI_TIMEOUT	The bulk transfer failed due to timeout.
EFI_DEVICE_ERROR	The bulk transfer failed due to host controller or device error. Caller should check <i>TransferResult</i> for detailed error information.

EFI_USB2_HC_PROTOCOL.AsyncInterruptTransfer()

Summary

Submits an asynchronous interrupt transfer to an interrupt endpoint of a USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_ASYNC_INTERRUPT_TRANSFER) (
    IN  EFI_USB2_HC_PROTOCOL      *This,
    IN  UINT8                     DeviceAddress,
    IN  UINT8                     EndPointAddress,
    IN  UINT8                     DeviceSpeed,
    IN  UINTN                     MaximumPacketLength,
    IN  BOOLEAN                   IsNewTransfer,
    IN OUT UINT8                  *DataToggle,
    IN  UINTN                     PollingInterval OPTIONAL,
    IN  UINTN                     DataLength      OPTIONAL,
    IN  EFI_USB2_HC_TRANSACTION_TRANSLATOR *Translator OPTIONAL,
    IN  EFI_ASYNC_USB_TRANSFER_CALLBACK CallBackFunction OPTIONAL,
    IN  VOID                       *Context       OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>DeviceAddress</i>	Represents the address of the target device on the USB, which is assigned during USB enumeration.
<i>EndPointAddress</i>	The combination of an endpoint number and an endpoint direction of the target USB device. Each endpoint address supports data transfer in one direction except the control endpoint (whose default endpoint address is zero). It is the caller's responsibility to make sure that the <i>EndPointAddress</i> represents an interrupt endpoint.
<i>DeviceSpeed</i>	Indicates device speed. See "Related Definitions" in EFI_USB2_HC_PROTOCOL.ControlTransfer() for a list of the supported values.
<i>MaximumPacketLength</i>	Indicates the maximum packet size the target endpoint is capable of sending or receiving.
<i>IsNewTransfer</i>	If TRUE , an asynchronous interrupt pipe is built between the host and the target interrupt endpoint. If FALSE , the specified asynchronous interrupt pipe is canceled. If TRUE , and an interrupt transfer exists for the target endpoint, then EFI_INVALID_PARAMETER is returned.
<i>DataToggle</i>	A pointer to the data toggle value. On input, it is valid when <i>IsNewTransfer</i> is TRUE , and it indicates the initial data

	toggle value the asynchronous interrupt transfer should adopt. On output, it is valid when <i>IsNewTransfer</i> is FALSE , and it is updated to indicate the data toggle value of the subsequent asynchronous interrupt transfer.
<i>PollingInterval</i>	Indicates the interval, in milliseconds, that the asynchronous interrupt transfer is polled. This parameter is required when <i>IsNewTransfer</i> is TRUE .
<i>DataLength</i>	Indicates the length of data to be received at the rate specified by <i>PollingInterval</i> from the target asynchronous interrupt endpoint. This parameter is only required when <i>IsNewTransfer</i> is TRUE .
<i>Translator</i>	A pointer to the transaction translator data.
<i>CallbackFunction</i>	The Callback function. This function is called at the rate specified by <i>PollingInterval</i> . This parameter is only required when <i>IsNewTransfer</i> is TRUE . Refer to UsbAsyncInterruptTransfer () (Section 16.2.4) for the definition of this function type.
<i>Context</i>	The context that is passed to the <i>CallbackFunction</i> . This is an optional parameter and may be NULL .

Description

This function is used to submit asynchronous interrupt transfer to a target endpoint of a USB device. The target endpoint is specified by *DeviceAddress* and *EndpointAddress*. In the USB Specification, Revision 2.0, interrupt transfer is one of the four USB transfer types. In the [EFI USB2 HC PROTOCOL](#), interrupt transfer is divided further into synchronous interrupt transfer and asynchronous interrupt transfer.

An asynchronous interrupt transfer is typically used to query a device’s status at a fixed rate. For example, keyboard, mouse, and hub devices use this type of transfer to query their interrupt endpoints at a fixed rate. The asynchronous interrupt transfer is intended to support the interrupt transfer type of “submit once, execute periodically.” Unless an explicit request is made, the asynchronous transfer will never retire.

If *IsNewTransfer* is **TRUE**, then an interrupt transfer is started at a fixed rate. The rate is specified by *PollingInterval*, the size of the receive buffer is specified by *DataLength*, and the callback function is specified by *CallbackFunction*. *Context* specifies an optional context that is passed to the *CallbackFunction* each time it is called. The *CallbackFunction* is intended to provide a means for the host to periodically process interrupt transfer data.

If *IsNewTransfer* is **TRUE**, and an interrupt transfer exists for the target end point, then **EFI_INVALID_PARAMETER** is returned.

If *IsNewTransfer* is **FALSE**, then the interrupt transfer is canceled.

EFI_INVALID_PARAMETER is returned if one of the following conditions is satisfied:

- Data transfer direction indicated by *EndPointAddress* is other than *EfiUsbDataIn*.
- *IsNewTransfer* is **TRUE** and *DataLength* is 0.
- *IsNewTransfer* is **TRUE** and *DataToggle* points to a value other than 0 and 1.

- *IsNewTransfer* is **TRUE** and *PollingInterval* is not in the range 1..255.
- *IsNewTransfer* requested where an interrupt transfer exists for the target end point.

Status Codes Returned

EFI_SUCCESS	The asynchronous interrupt transfer request has been successfully submitted or canceled.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in “Description” above. When an interrupt transfer exists for the target end point and a new transfer is requested, EFI_INVALID_PARAMETER is returned.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

EFI_USB2_HC_PROTOCOL.SyncInterruptTransfer()

Summary

Submits synchronous interrupt transfer to an interrupt endpoint of a USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_SYNC_INTERRUPT_TRANSFER) (
    IN      EFI_USB2_HC_PROTOCOL      *This,
    IN      UINT8                     DeviceAddress,
    IN      UINT8                     EndPointAddress,
    IN      UINT8                     DeviceSpeed,
    IN      UINTN                     MaximumPacketLength,
    IN OUT  VOID                      *Data,
    IN OUT  UINTN                     *DataLength,
    IN OUT  UINT8                     *DataToggle,
    IN      UINTN                     Timeout,
    IN EFI_USB2_HC_TRANSACTION_TRANSLATOR *Translator
    OUT     UINT32                    *TransferResult
);
```

Parameters

<i>This</i>	A pointer to the EFI USB2 HC PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>DeviceAddress</i>	Represents the address of the target device on the USB, which is assigned during USB enumeration.
<i>EndPointAddress</i>	The combination of an endpoint number and an endpoint direction of the target USB device. Each endpoint address supports data transfer in one direction except the control endpoint (whose default endpoint address is zero). It is the caller's responsibility to make sure that the <i>EndPointAddress</i> represents an interrupt endpoint.
<i>DeviceSpeed</i>	Indicates device speed. See "Related Definitions" in ControlTransfer() for a list of the supported values.
<i>MaximumPacketLength</i>	Indicates the maximum packet size the target endpoint is capable of sending or receiving.
<i>Data</i>	A pointer to the buffer of data that will be transmitted to USB device or received from USB device.
<i>DataLength</i>	On input, the size, in bytes, of the data buffer specified by <i>Data</i> . On output, the number of bytes transferred.
<i>DataToggle</i>	A pointer to the data toggle value. On input, it indicates the initial data toggle value the synchronous interrupt transfer should adopt; on output, it is updated to indicate the data toggle value of the subsequent synchronous interrupt transfer.

<i>TimeOut</i>	Indicates the maximum time, in milliseconds, which the transfer is allowed to complete.
<i>Translator</i>	A pointer to the transaction translator data.
<i>TransferResult</i>	A pointer to the detailed result information from the synchronous interrupt transfer. Refer to UsbControlTransfer() (Section 16.2.4) for transfer result types (EFI_USB_ERR_x).

Description

This function is used to submit a synchronous interrupt transfer to a target endpoint of a USB device. The target endpoint is specified by *DeviceAddress* and *EndpointAddress*. In the USB Specification, Revision 2.0, interrupt transfer is one of the four USB transfer types. In the [EFI USB2 HC PROTOCOL](#), interrupt transfer is divided further into synchronous interrupt transfer and asynchronous interrupt transfer.

The synchronous interrupt transfer is designed to retrieve small amounts of data from a USB device through an interrupt endpoint. A synchronous interrupt transfer is only executed once for each request. This is the most significant difference from the asynchronous interrupt transfer.

If the synchronous interrupt transfer is successful, then **EFI_SUCCESS** is returned. If the USB transfer cannot be completed within the timeout specified by *Timeout*, then **EFI_TIMEOUT** is returned. If an error other than timeout occurs during the USB transfer, then **EFI_DEVICE_ERROR** is returned and the detailed status code is returned in *TransferResult*. **EFI_INVALID_PARAMETER** is returned if one of the following conditions is satisfied:

- *Data* is **NULL**.
- *DataLength* is 0.
- *MaximumPacketLength* is not valid. The legal value of this parameter should be 3072 or less for high-speed device, 64 or less for a full-speed device; for a slow device, it is limited to 8 or less. For the full-speed device, it should be 8, 16, 32, or 64; for the slow device, it is limited to 8.
- *DataToggle* points to a value other than 0 and 1.
- *TransferResult* is **NULL**.

Status Codes Returned

EFI_SUCCESS	The synchronous interrupt transfer was completed successfully.
EFI_OUT_OF_RESOURCES	The synchronous interrupt transfer could not be submitted due to lack of resource.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in “Description” above.
EFI_TIMEOUT	The synchronous interrupt transfer failed due to timeout.
EFI_DEVICE_ERROR	The synchronous interrupt transfer failed due to host controller or device error. Caller should check <i>TransferResult</i> for detailed error information.

EFI_USB2_HC_PROTOCOL.IsochronousTransfer()

Summary

Submits isochronous transfer to an isochronous endpoint of a USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_ISOCHRONOUS_TRANSFER) (
    IN      EFI_USB2_HC_PROTOCOL  *This,
    IN      UINT8                 DeviceAddress,
    IN      UINT8                 EndPointAddress,
    IN      UINT8                 DeviceSpeed,
    IN      UINTN                 MaximumPacketLength,
    IN      UINT8                 DataBuffersNumber,
    IN OUT VOID                   *Data[EFI_USB_MAX_ISO_BUFFER_NUM],
    IN      UINTN                 DataLength,
    IN      EFI_USB2_HC_TRANSACTION_TRANSLATOR *Translator,
    OUT     UINT32                 *TransferResult
);
```

Related Definitions

```
#define EFI_USB_MAX_ISO_BUFFER_NUM    7
#define EFI_USB_MAX_ISO_BUFFER_NUM1  2
```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>DeviceAddress</i>	Represents the address of the target device on the USB, which is assigned during USB enumeration.
<i>EndPointAddress</i>	The combination of an endpoint number and an endpoint direction of the target USB device. Each endpoint address supports data transfer in one direction except the control endpoint (whose default endpoint address is 0). It is the caller's responsibility to make sure that the <i>EndPointAddress</i> represents an isochronous endpoint.
<i>DeviceSpeed</i>	Indicates device speed. The supported values are EFI_USB_SPEED_FULL , EFI_USB_SPEED_HIGH , or EFI_USB_SPEED_SUPER .
<i>MaximumPacketLength</i>	Indicates the maximum packet size the target endpoint is capable of sending or receiving. For isochronous endpoints, this value is used to reserve the bus time in the schedule, required for the per-frame data payloads. The pipe may, on an ongoing basis, actually use less bandwidth than that reserved.
<i>DataBuffersNumber</i>	Number of data buffers prepared for the transfer.

<i>Data</i>	Array of pointers to the buffers of data that will be transmitted to USB device or received from USB device.
<i>DataLength</i>	Specifies the length, in bytes, of the data to be sent to or received from the USB device.
<i>Translator</i>	A pointer to the transaction translator data. See <code>ControlTransfer()</code> “Description” for the detailed information of this data structure.
<i>TransferResult</i>	A pointer to the detail result information of the isochronous transfer. Refer to <code>UsbControlTransfer()</code> (Section 16.2.4) for transfer result types (<code>EFI_USB_ERR_x</code>).

Description

This function is used to submit isochronous transfer to a target endpoint of a USB device. The target endpoint is specified by *DeviceAddress* and *EndpointAddress*. Isochronous transfers are used when working with isochronous data. It provides periodic, continuous communication between the host and a device. Isochronous transfers can be used only by full-speed, high-speed, and super-speed devices.

High-speed isochronous transfers can be performed using multiple data buffers. The number of buffers that are actually prepared for the transfer is specified by *DataBuffersNumber*. For full-speed isochronous transfers this value is ignored.

Data represents a list of pointers to the data buffers. For full-speed isochronous transfers only the data pointed by *Data[0]* shall be used. For high-speed isochronous transfers and for the split transactions depending on *DataLength* there several data buffers can be used. For the high-speed isochronous transfers the total number of buffers must not exceed

`EFI_USB_MAX_ISO_BUFFER_NUM`. For split transactions performed on full-speed device by high-speed host controller the total number of buffers is limited to

`EFI_USB_MAX_ISO_BUFFER_NUM1` See “Related Definitions” for the

`EFI_USB_MAX_ISO_BUFFER_NUM` and `EFI_USB_MAX_ISO_BUFFER_NUM1` values.

If the isochronous transfer is successful, then `EFI_SUCCESS` is returned. The isochronous transfer is designed to be completed within one USB frame time, if it cannot be completed, `EFI_TIMEOUT` is returned. If an error other than timeout occurs during the USB transfer, then `EFI_DEVICE_ERROR` is returned and the detailed status code will be returned in *TransferResult*.

`EFI_INVALID_PARAMETER` is returned if one of the following conditions is satisfied:

- *Data* is `NULL`.
- *DataLength* is 0.
- *DeviceSpeed* is not one of the supported values listed above.
- *MaximumPacketLength* is invalid. *MaximumPacketLength* must be 1023 or less for full-speed devices, and 1024 or less for high-speed and super-speed devices.
- *TransferResult* is `NULL`.

Status Codes Returned

<code>EFI_SUCCESS</code>	The isochronous transfer was completed successfully.
--------------------------	--

EFI_OUT_OF_RESOURCES	The isochronous transfer could not be submitted due to lack of resource.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in “Description” above.
EFI_TIMEOUT	The isochronous transfer cannot be completed within the one USB frame time.
EFI_DEVICE_ERROR	The isochronous transfer failed due to host controller or device error. Caller should check <i>TransferResult</i> for detailed error information.
EFI_UNSUPPORTED	The implementation doesn’t support an Isochronous transfer function.

EFI_USB2_HC_PROTOCOL.AsyncIsochronousTransfer()

Summary

Submits nonblocking isochronous transfer to an isochronous endpoint of a USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USB2_HC_PROTOCOL_ASYNC_ISOCHRONOUS_TRANSFER) (
    IN      EFI_USB2_HC_PROTOCOL  *This,
    IN      UINT8                 DeviceAddress,
    IN      UINT8                 EndPointAddress,
    IN      UINT8                 DeviceSpeed,
    IN      UINTN                 MaximumPacketLength,
    IN      UINT8                 DataBuffersNumber,
    IN OUT VOID                   *Data[EFI_USB_MAX_ISO_BUFFER_NUM],
    IN      UINTN                 DataLength,
    IN      EFI_USB2_HC_TRANSACTION_TRANSLATOR *Translator,
    IN EFI_ASYNC_USB_TRANSFER_CALLBACK      IsochronousCallBack,
    IN VOID                   *Context      OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>DeviceAddress</i>	Represents the address of the target device on the USB, which is assigned during USB enumeration.
<i>EndPointAddress</i>	The combination of an endpoint number and an endpoint direction of the target USB device. Each endpoint address supports data transfer in one direction except the control endpoint (whose default endpoint address is zero). It is the caller's responsibility to make sure that the <i>EndPointAddress</i> represents an isochronous endpoint.
<i>DeviceSpeed</i>	Indicates device speed. The supported values are EFI_USB_SPEED_FULL , EFI_USB_SPEED_HIGH , or EFI_USB_SPEED_SUPER .
<i>MaximumPacketLength</i>	Indicates the maximum packet size the target endpoint is capable of sending or receiving. For isochronous endpoints, this value is used to reserve the bus time in the schedule, required for the per-frame data payloads. The pipe may, on an ongoing basis, actually use less bandwidth than that reserved.
<i>DataBuffersNumber</i>	Number of data buffers prepared for the transfer.
<i>Data</i>	Array of pointers to the buffers of data that will be transmitted to USB device or received from USB device.

<i>DataLength</i>	Specifies the length, in bytes, of the data to be sent to or received from the USB device.
<i>Translator</i>	A pointer to the transaction translator data. See <code>ControlTransfer()</code> “Description” for the detailed information of this data structure.
<i>IsochronousCallback</i>	The Callback function. This function is called if the requested isochronous transfer is completed. Refer to UsbAsyncInterruptTransfer() (Section 16.2.4) for the definition of this function type.
<i>Context</i>	Data passed to the <i>IsochronousCallback</i> function. This is an optional parameter and may be NULL .

Description

This is an asynchronous type of USB isochronous transfer. If the caller submits a USB isochronous transfer request through this function, this function will return immediately. When the isochronous transfer completes, the **IsochronousCallback** function will be triggered, the caller can know the transfer results. If the transfer is successful, the caller can get the data received or sent in this callback function.

The target endpoint is specified by *DeviceAddress* and *EndpointAddress*. Isochronous transfers are used when working with isochronous data. It provides periodic, continuous communication between the host and a device. Isochronous transfers can be used only by full-speed, high-speed, and super-speed devices.

High-speed isochronous transfers can be performed using multiple data buffers. The number of buffers that are actually prepared for the transfer is specified by *DataBuffersNumber*. For full-speed isochronous transfers this value is ignored.

Data represents a list of pointers to the data buffers. For full-speed isochronous transfers only the data pointed by *Data[0]* shall be used. For high-speed isochronous transfers and for the split transactions depending on *DataLength* there several data buffers can be used. For the high-speed isochronous transfers the total number of buffers must not exceed

EFI_USB_MAX_ISO_BUFFER_NUM. For split transactions performed on full-speed device by high-speed host controller the total number of buffers is limited to **EFI_USB_MAX_ISO_BUFFER_NUM1**. See “Related Definitions” in `IsochronousTransfer()` section for the **EFI_USB_MAX_ISO_BUFFER_NUM** and **EFI_USB_MAX_ISO_BUFFER_NUM1** values.

EFI_INVALID_PARAMETER is returned if one of the following conditions is satisfied:

- *Data* is **NULL**.
- *DataLength* is 0.
- *DeviceSpeed* is not one of the supported values listed above.
- *MaximumPacketLength* is invalid. *MaximumPacketLength* must be 1023 or less for full-speed devices and 1024 or less for high-speed and super-speed devices.

Status Codes Returned

EFI_SUCCESS	The asynchronous isochronous transfer was completed successfully.
-------------	---

Unified Extensible Firmware Interface Specification

EFI_OUT_OF_RESOURCES	The asynchronous isochronous transfer could not be submitted due to lack of resource.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in “Description” above.
EFI_UNSUPPORTED	The implementation doesn’t support Isochronous transfer function

EFI_USB2_HC_PROTOCOL.GetRootHubPortStatus()

Summary

Retrieves the current status of a USB root hub port.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_GET_ROOTHUB_PORT_STATUS) (
    IN  EFI_USB2_HC_PROTOCOL  *This,
    IN  UINT8                  PortNumber,
    OUT EFI_USB_PORT_STATUS   *PortStatus
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>PortNumber</i>	Specifies the root hub port from which the status is to be retrieved. This value is zero based. For example, if a root hub has two ports, then the first port is numbered 0, and the second port is numbered 1.
<i>PortStatus</i>	A pointer to the current port status bits and port status change bits. The type EFI_USB_PORT_STATUS is defined in “Related Definitions” below.

Related Definitions

```
typedef struct {
    UINT16  PortStatus;
    UINT16  PortChangeStatus;
} EFI_USB_PORT_STATUS;

//*****
// EFI_USB_PORT_STATUS.PortStatus bit definition
//*****
#define USB_PORT_STAT_CONNECTION      0x0001

PortStatus Contains current port status bitmap. The root hub port status bitmap is unified with the USB hub port status bitmap. See [Table 136](#) for a reference, which is borrowed from *Chapter 11, Hub Specification, of USB Specification, Revision 1.1*.

PortChangeStatus Contains current port status change bitmap. The root hub port change status bitmap is unified with the USB hub port status bitmap. See [Table 137](#) for a reference, which is borrowed from *Chapter 11, Hub Specification, of USB Specification, Revision 1.1*.

Table 136. USB Hub Port Status Bitmap

Bit	Description
0	Current Connect Status: (USB_PORT_STAT_CONNECTION) This field reflects whether or not a device is currently connected to this port. 0 = No device is present 1 = A device is present on this port
1	Port Enable / Disabled: (USB_PORT_STAT_ENABLE) Ports can be enabled by software only. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by software. 0 = Port is disabled 1 = Port is enabled
2	Suspend: (USB_PORT_STAT_SUSPEND) This field indicates whether or not the device on this port is suspended. 0 = Not suspended 1 = Suspended
3	Over-current Indicator: (USB_PORT_STAT_OVERCURRENT) This field is used to indicate that the current drain on the port exceeds the specified maximum. 0 = All no over-current condition exists on this port 1 = An over-current condition exists on this port
4	Reset: (USB_PORT_STAT_RESET) Indicates whether port is in reset state. 0 = Port is not in reset state 1 = Port is in reset state
5-7	Reserved These bits return 0 when read.
8	Port Power: (USB_PORT_STAT_POWER) This field reflects a port's logical, power control state. 0 = This port is in the Powered-off state 1 = This port is not in the Powered-off state

Bit	Description
9	<p>Low Speed Device Attached: (USB_PORT_STAT_LOW_SPEED) This is relevant only if a device is attached.</p> <p>0 = Full-speed device attached to this port 1 = Low-speed device attached to this port</p>
10	<p>High Speed Device Attached: (USB_PORT_STAT_HIGH_SPEED) This field indicates whether the connected device is high-speed device</p> <p>0 = High-speed device is not attached to this port 1 = High-speed device attached to this port</p> <p>NOTE: this bit has precedence over Bit 9; if set, bit 9 must be ignored.</p>
11	<p>Super Speed Device Attached: (USB_PORT_STAT_SUPER_SPEED) This field indicates whether the connected device is a super-speed device.</p> <p>0 = Super-speed device is not attached to this port. 1 = Super-speed device is attached to this port.</p> <p>NOTE: This bit has precedence over Bit 9 and Bit 10; if set bits 9,10 must be ignored.</p>
12	Reserved. Bit returns 0 when read.
13	<p>The host controller owns the specified port.</p> <p>0 = Controller does not own the port. 1 = Controller owns the port</p>
14-15	Reserved These bits return 0 when read.

Table 137. Hub Port Change Status Bitmap

Bit	Description
0	<p>Connect Status Change: (USB_PORT_STAT_C_CONNECTION) Indicates a change has occurred in the port's Current Connect Status.</p> <p>0 = No change has occurred to Current Connect status 1 = Current Connect status has changed</p>
1	<p>Port Enable /Disable Change: (USB_PORT_STAT_C_ENABLE)</p> <p>0 = No change 1 = Port enabled/disabled status has changed</p>
2	<p>Suspend Change: (USB_PORT_STAT_C_SUSPEND) This field indicates a change in the host-visible suspend state of the attached device.</p> <p>0 = No change 1 = Resume complete</p>
3	<p>Over-Current Indicator Change: (USB_PORT_STAT_C_OVERCURRENT)</p> <p>0 = No change has occurred to Over-Current Indicator 1 = Over-Current Indicator has changed</p>
4	<p>Reset Change: (USB_PORT_STAT_C_RESET) This field is set when reset processing on this port is complete.</p> <p>0 = No change 1 = Reset complete</p>
5-15	Reserved. These bits return 0 when read.

Description

This function is used to retrieve the status of the root hub port specified by *PortNumber*.

[EFI_USB_PORT_STATUS](#) describes the port status of a specified USB port. This data structure is designed to be common to both a USB root hub port and a USB hub port.

The number of root hub ports attached to the USB host controller can be determined with the function [GetRootHubPortStatus\(\)](#). If *PortNumber* is greater than or equal to the number of ports returned by [GetRootHubPortNumber\(\)](#), then **EFI_INVALID_PARAMETER** is returned. Otherwise, the status of the USB root hub port is returned in *PortStatus*, and **EFI_SUCCESS** is returned.

Status Codes Returned

EFI_SUCCESS	The status of the USB root hub port specified by <i>PortNumber</i> was returned in <i>PortStatus</i> .
EFI_INVALID_PARAMETER	<i>PortNumber</i> is invalid.

EFI_USB2_HC_PROTOCOL.SetRootHubPortFeature()

Summary

Sets a feature for the specified root hub port.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_SET_ROOTHUB_PORT_FEATURE) (
    IN EFI_USB2_HC_PROTOCOL    *This,
    IN UINT8                   PortNumber,
    IN EFI_USB_PORT_FEATURE    PortFeature
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>PortNumber</i>	Specifies the root hub port whose feature is requested to be set. This value is zero based. For example, if a root hub has two ports, then the first port is number 0, and the second port is numbered 1.
<i>PortFeature</i>	Indicates the feature selector associated with the feature set request. The port feature indicator is defined in “Related Definitions” and Table 138 below.

Related Definitions

```
typedef enum {
    EfiUsbPortEnable           = 1,
    EfiUsbPortSuspend         = 2,
    EfiUsbPortReset           = 4,
    EfiUsbPortPower           = 8,
    EfiUsbPortOwner           = 13,
    EfiUsbPortConnectChange   = 16,
    EfiUsbPortEnableChange    = 17,
    EfiUsbPortSuspendChange   = 18,
    EfiUsbPortOverCurrentChange = 19,
    EfiUsbPortResetChange     = 20
} EFI_USB_PORT_FEATURE;
```

The feature values specified in the enumeration variable have special meaning. Each value indicates its bit index in the port status and status change bitmaps, if combines these two bitmaps into a 32-bit bitmap. The meaning of each port feature is listed in [Table 138](#).

Table 138. USB Port Features

Port Feature	For SetRootHubPortFeature	For ClearRootHubPortFeature
EfiUsbPortEnable	Enable the given port of the root hub.	Disable the given port of the root hub.
EfiUsbPortSuspend	Put the given port into suspend state.	Restore the given port from the previous suspend state.
EfiUsbPortReset	Reset the given port of the root hub.	Clear the RESET signal for the given port of the root hub.
EfiUsbPortPower	Power the given port.	Shutdown the power from the given port.
EfiUsbPortOwner	N/A.	Releases the port ownership of this port to companion host controller.
EfiUsbPortConnectChange	N/A.	Clear USB_PORT_STAT_C_CONNECTION bit of the given port of the root hub.
EfiUsbPortEnableChange	N/A.	Clear USB_PORT_STAT_C_ENABLE bit of the given port of the root hub.
EfiUsbPortSuspendChange	N/A.	Clear USB_PORT_STAT_C_SUSPEND bit of the given port of the root hub.
EfiUsbPortOverCurrentChange	N/A.	Clear USB_PORT_STAT_C_OVERCURRENT bit of the given port of the root hub.
EfiUsbPortResetChange	N/A.	Clear USB_PORT_STAT_C_RESET bit of the given port of the root hub.

Description

This function sets the feature specified by *PortFeature* for the USB root hub port specified by *PortNumber*. Setting a feature enables that feature or starts a process associated with that feature. For the meanings about the defined features, please refer to [Table 136](#) and [Table 137](#).

The number of root hub ports attached to the USB host controller can be determined with the function [GetRootHubPortStatus\(\)](#). If *PortNumber* is greater than or equal to the number of ports returned by [GetRootHubPortNumber\(\)](#), then **EFI_INVALID_PARAMETER** is returned. If *PortFeature* is not **EfiUsbPortEnable**, **EfiUsbPortSuspend**, **EfiUsbPortReset** nor **EfiUsbPortPower**, then **EFI_INVALID_PARAMETER** is returned.

Status Codes Returned

EFI_SUCCESS	The feature specified by <i>PortFeature</i> was set for the USB root hub port specified by <i>PortNumber</i> .
EFI_INVALID_PARAMETER	<i>PortNumber</i> is invalid or <i>PortFeature</i> is invalid for this function.

EFI_USB2_HC_PROTOCOL.ClearRootHubPortFeature()

Summary

Clears a feature for the specified root hub port.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_CLEAR_ROOTHUB_PORT_FEATURE) (
    IN EFI_USB2_HC_PROTOCOL    *This
    IN UINT8                   PortNumber,
    IN EFI_USB_PORT_FEATURE    PortFeature
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB2_HC_PROTOCOL instance. Type EFI_USB2_HC_PROTOCOL is defined in Section 16.1 .
<i>PortNumber</i>	Specifies the root hub port whose feature is requested to be cleared. This value is zero-based. For example, if a root hub has two ports, then the first port is number 0, and the second port is numbered 1.
<i>PortFeature</i>	Indicates the feature selector associated with the feature clear request. The port feature indicator (EFI_USB_PORT_FEATURE) is defined in the “Related Definitions” section of the SetRootHubPortFeature() function description and in Table 138 .

Description

This function clears the feature specified by *PortFeature* for the USB root hub port specified by *PortNumber*. Clearing a feature disables that feature or stops a process associated with that feature. For the meanings about the defined features, refer to [Table 136](#) and [Table 137](#).

The number of root hub ports attached to the USB host controller can be determined with the function [GetRootHubPortStatus\(\)](#). If *PortNumber* is greater than or equal to the number of ports returned by [GetRootHubPortNumber\(\)](#), then [EFI_INVALID_PARAMETER](#) is returned. If *PortFeature* is not [EfiUsbPortEnable](#), [EfiUsbPortSuspend](#), [EfiUsbPortPower](#), [EfiUsbPortConnectChange](#), [EfiUsbPortResetChange](#), [EfiUsbPortEnableChange](#), [EfiUsbPortSuspendChange](#), or [EfiUsbPortOverCurrentChange](#), then [EFI_INVALID_PARAMETER](#) is returned.

Status Codes Returned

EFI_SUCCESS	The feature specified by <i>PortFeature</i> was cleared for the USB root hub port specified by <i>PortNumber</i> .
EFI_INVALID_PARAMETER	<i>PortNumber</i> is invalid or <i>PortFeature</i> is invalid.

16.2 USB Driver Model

16.2.1 Scope

[Section 16.2](#) describes the USB Driver Model. This includes the behavior of USB Bus Drivers, the behavior of a USB Device Drivers, and a detailed description of the EFI USB I/O Protocol. This document provides enough material to implement a USB Bus Driver, and the tools required to design and implement USB Device Drivers. It does not provide any information on specific USB devices.

The material contained in this section is designed to extend this specification and the *UEFI Driver Model* in a way that supports USB device drivers and USB bus drivers. These extensions are provided in the form of USB specific protocols. This document provides the information required to implement a USB Bus Driver in system firmware. The document also contains the information required by driver writers to design and implement USB Device Drivers that a platform may need to boot a UEFI-compliant OS.

The USB Driver Model described here is intended to be a foundation on which a USB Bus Driver and a wide variety of USB Device Drivers can be created. USB Driver Model Overview

The USB Driver Stack includes the USB Bus Driver, USB Host Controller Driver, and individual USB device drivers.

Figure 53. USB Bus Controller Handle

In the USB Bus Driver Design, the USB Bus Controller is managed by two drivers. One is USB Host Controller Driver, which consumes its parent bus **EFI_XYZ_IO_PROTOCOL**, and produces **EFI_USB2_HC_PROTOCOL** and attaches it to the Bus Controller Handle. The other one is USB Bus Driver, which consumes **EFI_USB2_HC_PROTOCOL**, and performs bus enumeration. [Figure 53](#) shows protocols that are attached to the USB Bus Controller Handle. Detailed descriptions are presented in the following sections.

16.2.2 USB Bus Driver

USB Bus Driver performs periodic Enumeration on the USB Bus. In USB bus enumeration, when a new USB controller is found, the bus driver does some standard configuration for that new controller, and creates a device handle for it. The [EFI_USB_IO_PROTOCOL](#) and the [EFI_DEVICE_PATH_PROTOCOL](#) are attached to the device handle so that the USB controller can be accessed. The USB Bus Driver is also responsible for connecting USB device drivers to USB controllers. When a USB device is detached from a USB bus, the USB bus driver will stop that USB controller, and uninstall the [EFI_USB_IO_PROTOCOL](#) and the [EFI_DEVICE_PATH_PROTOCOL](#) from that handle. A detailed description is given in [Section 16.2.2.3](#).

16.2.2.1 USB Bus Driver Entry Point

Like all other device drivers, the entry point for a USB Bus Driver attaches the [EFI_DRIVER_BINDING_PROTOCOL](#) to image handle of the USB Bus Driver.

16.2.2.2 Driver Binding Protocol for USB Bus Drivers

The Driver Binding Protocol contains three services. These are [Supported\(\)](#), [Start\(\)](#), and [Stop\(\)](#). [Supported\(\)](#) tests to see if the USB Bus Driver can manage a device handle. A USB Bus Driver can only manage a device handle that contains [EFI_USB2_HC_PROTOCOL](#).

The general idea is that the USB Bus Driver is a generic driver. Since there are several types of USB Host Controllers, an [EFI_USB2_HC_PROTOCOL](#) is used to abstract the host controller interface. Actually, a USB Bus Driver only requires an [EFI_USB2_HC_PROTOCOL](#).

The [Start\(\)](#) function tells the USB Bus Driver to start managing the USB Bus. In this function, the USB Bus Driver creates a device handle for the root hub, and creates a timer to monitor root hub connection changes.

The [Stop\(\)](#) function tells the USB Bus Driver to stop managing a USB Host Bus Controller. The [Stop\(\)](#) function simply deconfigures the devices attached to the root hub. The deconfiguration is a recursive process. If the device to be deconfigured is a USB hub, then all USB devices attached to its downstream ports will be deconfigured first, then itself. If all of the child devices handles have been destroyed then the [EFI_USB2_HC_PROTOCOL](#) is closed. Finally, the [Stop\(\)](#) function will then place the USB Host Bus Controller in a quiescent state.

16.2.2.3 USB Hot-Plug Event

Hot-Plug is one of the most important features provided by USB. A USB bus driver implements this feature through two methods. There are two types of hubs defined in the USB specification. One is the USB root hub, which is implemented in the USB Host controller. A timer event is created for the root hub. The other one is a USB Hub. An event is created for each hub that is correctly configured. All these events are associated with the same trigger which is USB bus numerator.

When USB bus enumeration is triggered, the USB Bus Driver checks the source of the event. This is required because the root hub differs from standard USB hub in checking the hub status. The status of a root hub is retrieved through the [EFI_USB2_HC_PROTOCOL](#), and that status of a standard USB hub is retrieved through a USB control transfer. A detailed description of the enumeration process is presented in the next section.

16.2.2.4 USB Bus Enumeration

When the periodic timer or the hubs notify event is signaled, the USB Bus Driver will perform bus enumeration.

1. Determine if the event is from the root hub or a standard USB hub.
2. Determine the port on which the connection change event occurred.
3. Determine if it is a connection change or a disconnection change.
4. If a connect change is detected, then a new device has been attached. Perform the following:
 - a. Reset and enable that port.
 - b. Configure the new device.
 - c. Parse the device configuration descriptors; get all of its interface descriptors (i.e., all USB controllers), and configure each interface.
 - d. Create a new handle for each interface (USB Controller) within the USB device. Attach the [EFI_DEVICE_PATH_PROTOCOL](#), and the [EFI_USB_IO_PROTOCOL](#) to each handle.
 - e. Connect the USB Controller to a USB device driver with the Boot Service [EFI_BOOT_SERVICES.ConnectController\(\)](#) if applicable.
 - f. If the USB Controller is a USB hub, create a Hub notify event which is associated with the USB Bus Enumerator, and submit an Asynchronous Interrupt Transfer Request (See [Section 16.2.4](#)).
5. If a disconnect change, then a device has been detached from the USB Bus. Perform the following:
 - a. If the device is not a USB Hub, then find and deconfigure the USB Controllers within the device. Then, stop each USB controller with [EFI_BOOT_SERVICES.DisconnectController\(\)](#), and uninstall the [EFI_DEVICE_PATH_PROTOCOL](#) and the [EFI_USB_IO_PROTOCOL](#) from the controller's handle. If the [EFI_BOOT_SERVICES.DisconnectController\(\)](#) call fails this process must be retried on a subsequent timer tick.
 - b. If the USB controller is USB hub controller, first find and deconfigure all its downstream USB devices (this is a recursive process, since there may be additional USB hub controllers on the downstream ports), then deconfigure USB hub controller itself.

16.2.3 USB Device Driver

A USB Device Driver manages a USB Controller and produces a device abstraction for use by a preboot application.

16.2.3.1 USB Device Driver Entry Point

Like all other device drivers, the entry point for a USB Device Driver attaches [EFI_DRIVER_BINDING_PROTOCOL](#) to image handle of the USB Device Driver.

16.2.3.2 Driver Binding Protocol for USB Device Drivers

The Driver Binding Protocol contains three services. These are [Supported\(\)](#), [Start\(\)](#), and [Stop\(\)](#).

The **Supported()** tests to see if the USB Device Driver can manage a device handle. This function checks to see if a controller can be managed by the USB Device Driver. This is done by opening the **EFI_USB_IO_PROTOCOL** bus abstraction on the USB Controller handle, and using the **EFI_USB_IO_PROTOCOL** services to determine if this USB Controller matches the profile that the USB Device Driver is capable of managing.

The **Start()** function tells the USB Device Driver to start managing a USB Controller. It opens the **EFI_USB_IO_PROTOCOL** instance from the handle for the USB Controller. This protocol instance is used to perform USB packet transmission over the USB bus. For example, if the USB controller is USB keyboard, then the USB keyboard driver would produce and install the **EFI_SIMPLE_TEXT_INPUT_PROTOCOL** to the USB controller handle.

The **Stop()** function tells the USB Device Driver to stop managing a USB Controller. It removes the I/O abstraction protocol instance previously installed in **Start()** from the USB controller handle. It then closes the **EFI_USB_IO_PROTOCOL**.

16.2.4 USB I/O Protocol

This section provides a detailed description of the **EFI_USB_IO_PROTOCOL**. This protocol is used by code, typically drivers, running in the EFI boot services environment to access USB devices like USB keyboards, mice and mass storage devices. In particular, functions for managing devices on USB buses are defined here.

The interfaces provided in the **EFI_USB_IO_PROTOCOL** are for performing basic operations to access USB devices. Typically, USB devices are accessed through the four different transfers types:

<i>Controller Transfer</i>	Typically used to configure the USB device into an operation mode.
<i>Interrupt Transfer</i>	Typically used to get periodic small amount of data, like USB keyboard and mouse.
<i>Bulk Transfer</i>	Typically used to transfer large amounts of data like reading blocks from USB mass storage devices.
<i>Isochronous Transfer</i>	Typically used to transfer data at a fixed rate like voice data.

This protocol also provides mechanisms to manage and configure USB devices and controllers.

EFI_USB_IO_PROTOCOL

Summary

Provides services to manage and communicate with USB devices.

GUID

```
#define EFI_USB_IO_PROTOCOL_GUID \
    { 0x2B2F68D6, 0x0CD2, 0x44cf, \
      0x0x8E, 0x8B, 0xBB, 0xA2, 0x0B, 0x1B, 0x5B, 0x75 }
```

Protocol Interface Structure

```
typedef struct _EFI_USB_IO_PROTOCOL {
```

```

EFI_USB_IO_CONTROL_TRANSFER           UsbControlTransfer;
EFI_USB_IO_BULK_TRANSFER              UsbBulkTransfer;
EFI_USB_IO_ASYNC_INTERRUPT_TRANSFER   UsbAsyncInterruptTransfer;
EFI_USB_IO_SYNC_INTERRUPT_TRANSFER    UsbSyncInterruptTransfer
EFI_USB_IO_ISOCHRONOUS_TRANSFER       UsbIsochronousTransfer;
EFI_USB_IO_ASYNC_ISOCHRONOUS_TRANSFER UsbAsyncIsochronousTransfer;
EFI_USB_IO_GET_DEVICE_DESCRIPTOR      UsbGetDeviceDescriptor;
EFI_USB_IO_GET_CONFIG_DESCRIPTOR      UsbGetConfigDescriptor;
EFI_USB_IO_GET_INTERFACE_DESCRIPTOR   UsbGetInterfaceDescriptor;
EFI_USB_IO_GET_ENDPOINT_DESCRIPTOR    UsbGetEndpointDescriptor;
EFI_USB_IO_GET_STRING_DESCRIPTOR      UsbGetStringDescriptor;
EFI_USB_IO_GET_SUPPORTED_LANGUAGES    UsbGetSupportedLanguages;
EFI_USB_IO_PORT_RESET                 UsbPortReset;
} EFI_USB_IO_PROTOCOL;

```

Parameters

- UsbControlTransfer* Accesses the USB Device through USB Control Transfer Pipe. See the [UsbControlTransfer \(\)](#) function description.
- UsbBulkTransfer* Accesses the USB Device through USB Bulk Transfer Pipe. See the [UsbBulkTransfer \(\)](#) function description.
- UsbAsyncInterruptTransfer* Non-block USB interrupt transfer. See the [UsbAsyncInterruptTransfer \(\)](#) function description.
- UsbSyncInterruptTransfer* Accesses the USB Device through USB Synchronous Interrupt Transfer Pipe. See the [UsbSyncInterruptTransfer \(\)](#) function description.
- UsbIsochronousTransfer* Accesses the USB Device through USB Isochronous Transfer Pipe. See the [UsbIsochronousTransfer \(\)](#) function description.
- UsbAsyncIsochronousTransfer* Nonblock USB isochronous transfer. See the [UsbAsyncIsochronousTransfer \(\)](#) function description.
- UsbGetDeviceDescriptor* Retrieves the device descriptor of a USB device. See the [UsbGetDeviceDescriptor \(\)](#) function description.
- UsbGetConfigDescriptor* Retrieves the activated configuration descriptor of a USB device. See the [UsbGetConfigDescriptor \(\)](#) function description.

UsbGetInterfaceDescriptor

Retrieves the interface descriptor of a USB Controller. See the [UsbGetInterfaceDescriptor \(\)](#) function description.

UsbGetEndpointDescriptor

Retrieves the endpoint descriptor of a USB Controller. See the [UsbGetEndpointDescriptor \(\)](#) function description.

UsbGetStringDescriptor

Retrieves the string descriptor inside a USB Device. See the [UsbGetStringDescriptor \(\)](#) function description.

UsbGetSupportedLanguages

Retrieves the array of languages that the USB device supports. See the [UsbGetSupportedLanguages \(\)](#) function description.

UsbPortReset

Resets and reconfigures the USB controller. See the [UsbPortReset \(\)](#) function description.

Description

The **EFI_USB_IO_PROTOCOL** provides four basic transfers types described in the *USB 1.1 Specification*. These include control transfer, interrupt transfer, bulk transfer and isochronous transfer. The **EFI_USB_IO_PROTOCOL** also provides some basic USB device/controller management and configuration interfaces. A USB device driver uses the services of this protocol to manage USB devices.

EFI_USB_IO_PROTOCOL.UsbControlTransfer()

Summary

This function is used to manage a USB device with a control transfer pipe. A control transfer is typically used to perform device initialization and configuration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_CONTROL_TRANSFER) (
    IN      EFI_USB_IO_PROTOCOL      *This,
    IN      EFI_USB_DEVICE_REQUEST   *Request,
    IN      EFI_USB_DATA_DIRECTION   Direction,
    IN      UINT32                    Timeout,
    IN OUT  VOID                      *Data      OPTIONAL,
    IN      UINTN                     DataLength OPTIONAL,
    OUT     UINT32                    *Status
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB_IO_PROTOCOL instance. Type EFI_USB_IO_PROTOCOL is defined in Section 16.2.4 .
<i>Request</i>	A pointer to the USB device request that will be sent to the USB device. See “Related Definitions” below.
<i>Direction</i>	Indicates the data direction. See “Related Definitions” below for this type.
<i>Data</i>	A pointer to the buffer of data that will be transmitted to USB device or received from USB device.
<i>Timeout</i>	Indicating the transfer should be completed within this time frame. The units are in milliseconds. If <i>Timeout</i> is 0, then the caller must wait for the function to be completed until EFI_SUCCESS or EFI_DEVICE_ERROR is returned.
<i>DataLength</i>	The size, in bytes, of the data buffer specified by <i>Data</i> .
<i>Status</i>	A pointer to the result of the USB transfer.

Related Definitions

```
typedef enum {
    EfiUsbDataIn,
    EfiUsbDataOut,
    EfiUsbNoData
} EFI_USB_DATA_DIRECTION;
```

```

//
// Error code for USB Transfer Results
//
#define EFI_USB_NOERROR           0x0000
#define EFI_USB_ERR_NOTEXECUTE    0x0001
#define EFI_USB_ERR_STALL         0x0002
#define EFI_USB_ERR_BUFFER        0x0004
#define EFI_USB_ERR_BABBLE        0x0008
#define EFI_USB_ERR_NAK           0x0010
#define EFI_USB_ERR_CRC           0x0020
#define EFI_USB_ERR_TIMEOUT       0x0040
#define EFI_USB_ERR_BITSTUFF      0x0080
#define EFI_USB_ERR_SYSTEM        0x0100

typedef struct {
    UINT8      RequestType;
    UINT8      Request;
    UINT16     Value;
    UINT16     Index;
    UINT16     Length;
} EFI_USB_DEVICE_REQUEST;

```

<i>RequestType</i>	The field identifies the characteristics of the specific request.
<i>Request</i>	This field specifies the particular request.
<i>Value</i>	This field is used to pass a parameter to USB device that is specific to the request.
<i>Index</i>	This field is also used to pass a parameter to USB device that is specific to the request.
<i>Length</i>	This field specifies the length of the data transferred during the second phase of the control transfer. If it is 0, then there is no data phase in this transfer.

Description

This function allows a USB device driver to communicate with the USB device through a Control Transfer. There are three control transfer types according to the data phase. If the *Direction* parameter is **EfiUsbNoData**, *Data* is **NULL**, and *DataLength* is 0, then no data phase exists for the control transfer. If the *Direction* parameter is **EfiUsbDataOut**, then *Data* specifies the data to be transmitted to the device, and *DataLength* specifies the number of bytes to transfer to the device. In this case there is an OUT DATA stage followed by a SETUP stage. If the *Direction* parameter is **EfiUsbDataIn**, then *Data* specifies the data that is received from the device, and *DataLength* specifies the number of bytes to receive from the device. In this case there is an IN DATA stage followed by a SETUP stage. After the USB transfer has completed successfully, **EFI_SUCCESS** is returned. If the transfer cannot be completed due to timeout, then **EFI_TIMEOUT** is returned. If an error other than timeout occurs during the USB transfer, then **EFI_DEVICE_ERROR** is returned and the detailed status code is returned in *Status*.

Status Code Returned

EFI_SUCCESS	The control transfer has been successfully executed.
EFI_INVALID_PARAMETER	The parameter <i>Direction</i> is not valid.
EFI_INVALID_PARAMETER	<i>Request</i> is NULL .
EFI_INVALID_PARAMETER	<i>Status</i> is NULL .
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.
EFI_TIMEOUT	The control transfer fails due to timeout.
EFI_DEVICE_ERROR	The transfer failed. The transfer status is returned in <i>Status</i> .

EFI_USB_IO_PROTOCOL.UsbBulkTransfer()

Summary

This function is used to manage a USB device with the bulk transfer pipe. Bulk Transfers are typically used to transfer large amounts of data to/from USB devices.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_USB_IO_BULK_TRANSFER) (
    IN      EFI_USB_IO_PROTOCOL  *This,
    IN      UINT8                DeviceEndpoint,
    IN      OUT VOID             *Data,
    IN OUT  UINTN                *DataLength,
    IN      UINTN                Timeout,
    OUT     UINT32               *Status
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB_IO_PROTOCOL instance. Type EFI_USB_IO_PROTOCOL is defined in Section 16.2.4 .
<i>DeviceEndpoint</i>	The destination USB device endpoint to which the device request is being sent. <i>DeviceEndpoint</i> must be between 0x01 and 0x0F or between 0x81 and 0x8F, otherwise EFI_INVALID_PARAMETER is returned. If the endpoint is not a BULK endpoint, EFI_INVALID_PARAMETER is returned. The MSB of this parameter indicates the endpoint direction. The number “1” stands for an IN endpoint, and “0” stands for an OUT endpoint.
<i>Data</i>	A pointer to the buffer of data that will be transmitted to USB device or received from USB device.
<i>DataLength</i>	On input, the size, in bytes, of the data buffer specified by <i>Data</i> . On output, the number of bytes that were actually transferred.
<i>Timeout</i>	Indicating the transfer should be completed within this time frame. The units are in milliseconds. If <i>Timeout</i> is 0, then the caller must wait for the function to be completed until EFI_SUCCESS or EFI_DEVICE_ERROR is returned.
<i>Status</i>	This parameter indicates the USB transfer status.

Description

This function allows a USB device driver to communicate with the USB device through Bulk Transfer. The transfer direction is determined by the endpoint direction. If the USB transfer is successful, then [EFI_SUCCESS](#) is returned. If USB transfer cannot be completed within the *Timeout* frame, [EFI_TIMEOUT](#) is returned. If an error other than timeout occurs during the USB transfer, then [EFI_DEVICE_ERROR](#) is returned and the detailed status code will be returned in the *Status* parameter.

Status Code Returned

EFI_SUCCESS	The bulk transfer has been successfully executed.
EFI_INVALID_PARAMETER	If <i>DeviceEndpoint</i> is not valid.
EFI_INVALID_PARAMETER	<i>Data</i> is NULL .
EFI_INVALID_PARAMETER	<i>DataLength</i> is NULL .
EFI_INVALID_PARAMETER	<i>Status</i> is NULL .
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.
EFI_TIMEOUT	The bulk transfer cannot be completed within <i>Timeout</i> timeframe.
EFI_DEVICE_ERROR	The transfer failed other than timeout, and the transfer status is returned in <i>Status</i> .

EFI_USB_IO_PROTOCOL.UsbAsyncInterruptTransfer()

Summary

This function is used to manage a USB device with an interrupt transfer pipe. An Asynchronous Interrupt Transfer is typically used to query a device’s status at a fixed rate. For example, keyboard, mouse, and hub devices use this type of transfer to query their interrupt endpoints at a fixed rate.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_ASYNC_INTERRUPT_TRANSFER) (
    IN EFI_USB_IO_PROTOCOL          *This,
    IN UINT8                        DeviceEndpoint,
    IN BOOLEAN                       IsNewTransfer,
    IN UINTN                         PollingInterval    OPTIONAL,
    IN UINTN                         DataLength          OPTIONAL,
    IN EFI_ASYNC_USB_TRANSFER_CALLBACK InterruptCallback OPTIONAL,
    IN VOID                          *Context           OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB_IO_PROTOCOL instance. Type EFI_USB_IO_PROTOCOL is defined in Section 16.2.4 .
<i>DeviceEndpoint</i>	The destination USB device endpoint to which the device request is being sent. <i>DeviceEndpoint</i> must be between 0x01 and 0x0F or between 0x81 and 0x8F, otherwise EFI_INVALID_PARAMETER is returned. If the endpoint is not an INTERRUPT endpoint, EFI_INVALID_PARAMETER is returned. The MSB of this parameter indicates the endpoint direction. The number “1” stands for an IN endpoint, and “0” stands for an OUT endpoint.
<i>IsNewTransfer</i>	If TRUE , a new transfer will be submitted to USB controller. If FALSE , the interrupt transfer is deleted from the device’s interrupt transfer queue. If TRUE , and an interrupt transfer exists for the target end point, then EFI_INVALID_PARAMETER is returned.
<i>PollingInterval</i>	Indicates the periodic rate, in milliseconds, that the transfer is to be executed. This parameter is required when <i>IsNewTransfer</i> is TRUE . The value must be between 1 to 255, otherwise EFI_INVALID_PARAMETER is returned. The units are in milliseconds.
<i>DataLength</i>	Specifies the length, in bytes, of the data to be received from the USB device. This parameter is only required when <i>IsNewTransfer</i> is TRUE .
<i>Context</i>	Data passed to the <i>InterruptCallback</i> function. This is an optional parameter and may be NULL .

InterruptCallback The Callback function. This function is called if the asynchronous interrupt transfer is completed. This parameter is required when *IsNewTransfer* is **TRUE**. See “Related Definitions” for the definition of this type.

Related Definitions

```
typedef
EFI_STATUS
(EFI_API * EFI_ASYNC_USB_TRANSFER_CALLBACK) (
    IN VOID      *Data,
    IN UINTN     DataLength,
    IN VOID      *Context,
    IN UINT32    Status
);
```

Data Data received or sent via the USB Asynchronous Transfer, if the transfer completed successfully.

DataLength The length of *Data* received or sent via the Asynchronous Transfer, if transfer successfully completes.

Context Data passed from [UsbAsyncInterruptTransfer\(\)](#) request.

Status Indicates the result of the asynchronous transfer.

Description

This function allows a USB device driver to communicate with a USB device with an Interrupt Transfer. Asynchronous Interrupt transfer is different than the other four transfer types because it is a nonblocking transfer. The interrupt endpoint is queried at a fixed rate, and the data transfer direction is always in the direction from the USB device towards the system.

If *IsNewTransfer* is **TRUE**, then an interrupt transfer is started at a fixed rate. The rate is specified by *PollingInterval*, the size of the receive buffer is specified by *DataLength*, and the callback function is specified by *InterruptCallback*. If *IsNewTransfer* is **TRUE**, and an interrupt transfer exists for the target end point, then **EFI_INVALID_PARAMETER** is returned.

If *IsNewTransfer* is **FALSE**, then the interrupt transfer is canceled.

Status Code Returned

EFI_SUCCESS	The asynchronous USB transfer request has been successfully executed.
EFI_DEVICE_ERROR	The asynchronous USB transfer request failed. When an interrupt transfer exists for the target end point and a new transfer is requested, EFI_INVALID_PARAMETER is returned.

Examples

Below is an example of how an asynchronous interrupt transfer is used. The example shows how a USB Keyboard Device Driver can periodically receive data from interrupt endpoint.

```

EFI_USB_IO_PROTOCOL          *UsbIo;
EFI_STATUS                   Status;
USB_KEYBOARD_DEV             *UsbKeyboardDevice;
EFI_USB_INTERRUPT_CALLBACK   KeyboardHandle;

. . .
Status = UsbIo->UsbAsyncInterruptTransfer(
    UsbIo,
    UsbKeyboardDevice->IntEndpointAddress,
    TRUE,
    UsbKeyboardDevice->IntPollingInterval,
    8,
    KeyboardHandler,
    UsbKeyboardDevice
);

. . .

//
// The following is the InterruptCallback function. If there is
// any results got from Asynchronous Interrupt Transfer,
// this function will be called.
//
EFI_STATUS
KeyboardHandler(
    IN VOID          *Data,
    IN UINTN         DataLength,
    IN VOID          *Context,
    IN UINT32        Result
)
{
    USB_KEYBOARD_DEV *UsbKeyboardDevice;
    UINTN            I;

    if(EFI_ERROR(Result))
    {
        //
        // Something error during this transfer,
        // just to some recovery work
        //
        . . .
        . . .
        return EFI_DEVICE_ERROR;
    }

    UsbKeyboardDevice = (USB_KEYBOARD_DEV *)Context;

    for(I = 0; I < DataLength; I++)

```

Unified Extensible Firmware Interface Specification

```
    {  
        ParsedData(Data[I]);  
        . . .  
    }  
  
    return EFI_SUCCESS;  
}
```

EFI_USB_IO_PROTOCOL.UsbSyncInterruptTransfer()

Summary

This function is used to manage a USB device with an interrupt transfer pipe. The difference between [UsbAsyncInterruptTransfer\(\)](#) and **UsbSyncInterruptTransfer()** is that the Synchronous interrupt transfer will only be executed one time. Once it returns, regardless of its status, the interrupt request will be deleted in the system.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_SYNC_INTERRUPT_TRANSFER) (
    IN      EFI_USB_IO_PROTOCOL  *This,
    IN      UINT8                DeviceEndpoint,
    IN OUT VOID                  *Data,
    IN OUT UINTN                 *DataLength,
    IN      UINTN                 Timeout,
    OUT     UINT32                *Status
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB_IO_PROTOCOL instance. Type EFI_USB_IO_PROTOCOL is defined in Section 16.2.4 .
<i>DeviceEndpoint</i>	The destination USB device endpoint to which the device request is being sent. <i>DeviceEndpoint</i> must be between 0x01 and 0x0F or between 0x81 and 0x8F, otherwise EFI_INVALID_PARAMETER is returned. If the endpoint is not an INTERRUPT endpoint, EFI_INVALID_PARAMETER is returned. The MSB of this parameter indicates the endpoint direction. The number “1” stands for an IN endpoint, and “0” stands for an OUT endpoint.
<i>Data</i>	A pointer to the buffer of data that will be transmitted to USB device or received from USB device.
<i>DataLength</i>	On input, then size, in bytes, of the buffer <i>Data</i> . On output, the amount of data actually transferred.
<i>Timeout</i>	The time out, in milliseconds, for this transfer. If <i>Timeout</i> is 0, then the caller must wait for the function to be completed until EFI_SUCCESS or EFI_DEVICE_ERROR is returned. If the transfer is not completed in this time frame, then EFI_TIMEOUT is returned.
<i>Status</i>	This parameter indicates the USB transfer status.

Description

This function allows a USB device driver to communicate with a USB device through a synchronous interrupt transfer. The **UsbSyncInterruptTransfer()** differs from

[UsbAsyncInterruptTransfer\(\)](#) described in the previous section in that it is a blocking transfer request. The caller must wait for the function return, either successfully or unsuccessfully.

Status Code Returned

EFI_SUCCESS	The sync interrupt transfer has been successfully executed.
EFI_INVALID_PARAMETER	The parameter <i>DeviceEndpoint</i> is not valid.
EFI_INVALID_PARAMETER	<i>Data</i> is NULL .
EFI_INVALID_PARAMETER	<i>DataLength</i> is NULL .
EFI_INVALID_PARAMETER	<i>Status</i> is NULL .
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.
EFI_TIMEOUT	The transfer cannot be completed within <i>Timeout</i> timeframe.
EFI_DEVICE_ERROR	The transfer failed other than timeout, and the transfer status is returned in <i>Status</i> .

EFI_USB_IO_PROTOCOL.UsbIsochronousTransfer()

Summary

This function is used to manage a USB device with an isochronous transfer pipe. An Isochronous transfer is typically used to transfer streaming data.

Prototype

```
typedef
EFI_STATUS
(EFI_API * EFI_USB_IO_ISOCHRONOUS_TRANSFER) (
    IN      EFI_USB_IO_PROTOCOL  *This,
    IN      UINT8                 DeviceEndpoint,
    IN OUT  VOID                  *Data,
    IN      UINTN                 DataLength,
    OUT     UINT32                 *Status
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB_IO_PROTOCOL instance. Type EFI_USB_IO_PROTOCOL is defined in Section 16.2.4 .
<i>DeviceEndpoint</i>	The destination USB device endpoint to which the device request is being sent. <i>DeviceEndpoint</i> must be between 0x01 and 0x0F or between 0x81 and 0x8F, otherwise EFI_INVALID_PARAMETER is returned. If the endpoint is not an ISOCHRONOUS endpoint, EFI_INVALID_PARAMETER is returned. The MSB of this parameter indicates the endpoint direction. The number “1” stands for an IN endpoint, and “0” stands for an OUT endpoint.
<i>Data</i>	A pointer to the buffer of data that will be transmitted to USB device or received from USB device.
<i>DataLength</i>	The size, in bytes, of the data buffer specified by <i>Data</i> .
<i>Status</i>	This parameter indicates the USB transfer status.

Description

This function allows a USB device driver to communicate with a USB device with an Isochronous Transfer. The type of transfer is different than the other types because the USB Bus Driver will not attempt to perform error recovery if transfer fails. If the USB transfer is completed successfully, then [EFI_SUCCESS](#) is returned. The isochronous transfer is designed to be completed within 1 USB frame time, if it cannot be completed, [EFI_TIMEOUT](#) is returned. If the transfer fails due to other reasons, then [EFI_DEVICE_ERROR](#) is returned and the detailed error status is returned in *Status*. If the data length exceeds the maximum payload per USB frame time, then it is this function’s responsibility to divide the data into a set of smaller packets that fit into a USB frame time. If all the packets are transferred successfully, then [EFI_SUCCESS](#) is returned.

Status Code Returned

EFI_SUCCESS	The isochronous transfer has been successfully executed.
EFI_INVALID_PARAMETER	The parameter <i>DeviceEndpoint</i> is not valid.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.
EFI_TIMEOUT	The transfer cannot be completed within the 1 USB frame time.
EFI_DEVICE_ERROR	The transfer failed due to the reason other than timeout, The error status is returned in <i>Status</i> .
EFI_UNSUPPORTED	The implementation doesn't support an Isochronous transfer function.

EFI_USB_IO_PROTOCOL.UsbAsyncIsochronousTransfer()

Summary

This function is used to manage a USB device with an isochronous transfer pipe. An asynchronous Isochronous transfer is a nonblocking USB isochronous transfer.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_ASYNC_ISOCHRONOUS_TRANSFER) (
    IN EFI_USB_IO_PROTOCOL          *This,
    IN UINT8                        DeviceEndpoint,
    IN OUT VOID                      *Data,
    IN UINTN                         DataLength,
    IN EFI_ASYNC_USB_TRANSFER_CALLBACK IsochronousCallback,
    IN VOID                          *Context          OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB_IO_PROTOCOL instance. Type EFI_USB_IO_PROTOCOL is defined in Section 16.2.4 .
<i>DeviceEndpoint</i>	The destination USB device endpoint to which the device request is being sent. <i>DeviceEndpoint</i> must be between 0x01 and 0x0F or between 0x81 and 0x8F, otherwise EFI_INVALID_PARAMETER is returned. If the endpoint is not an ISOCHRONOUS endpoint, EFI_INVALID_PARAMETER is returned. The MSB of this parameter indicates the endpoint direction. The number “1” stands for an IN endpoint, and “0” stands for an OUT endpoint.
<i>Data</i>	A pointer to the buffer of data that will be transmitted to USB device or received from USB device.
<i>DataLength</i>	Specifies the length, in bytes, of the data to be sent to or received from the USB device.
<i>Context</i>	Data passed to the IsochronousCallback () function. This is an optional parameter and may be NULL.
<i>IsochronousCallback</i>	The IsochronousCallback () function. This function is called if the requested isochronous transfer is completed. See the “Related Definitions” section of the UsbAsyncInterruptTransfer () function description.

Description

This is an asynchronous type of USB isochronous transfer. If the caller submits a USB isochronous transfer request through this function, this function will return immediately. When the isochronous transfer completes, the [IsochronousCallback \(\)](#) function will be triggered, the caller can

know the transfer results. If the transfer is successful, the caller can get the data received or sent in this callback function.

Status Code Returned

EFI_SUCCESS	The asynchronous isochronous transfer has been successfully submitted to the system.
EFI_INVALID_PARAMETER	The parameter <i>DeviceEndpoint</i> is not valid.
EFI_OUT_OF_RESOURCES	The request could not be submitted due to a lack of resources.
EFI_UNSUPPORTED	The implementation doesn't support an asynchronous Isochronous transfer function.

EFI_USB_IO_PROTOCOL.UsbGetDeviceDescriptor()

Summary

Retrieves the USB Device Descriptor.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_DEVICE_DESCRIPTOR) (
    IN  EFI_USB_IO_PROTOCOL      *This,
    OUT EFI_USB_DEVICE_DESCRIPTOR *DeviceDescriptor
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB_IO_PROTOCOL instance. Type EFI_USB_IO_PROTOCOL is defined in Section 16.2.4 .
<i>DeviceDescriptor</i>	A pointer to the caller allocated USB Device Descriptor. See “Related Definitions” for a detailed description.

Related Definitions

```
//
// See USB1.1 for detail description.
//
typedef struct {
    UINT8    Length;
    UINT8    DescriptorType;
    UINT16   BcdUSB;
    UINT8    DeviceClass;
    UINT8    DeviceSubClass;
    UINT8    DeviceProtocol;
    UINT8    MaxPacketSize0;
    UINT16   IdVendor;
    UINT16   IdProduct;
    UINT16   BcdDevice;
    UINT8    StrManufacturer;
    UINT8    StrProduct;
    UINT8    StrSerialNumber;
    UINT8    NumConfigurations;
} EFI_USB_DEVICE_DESCRIPTOR;
```

Description

This function is used to retrieve information about USB devices. This information includes the device class, subclass, and the number of configurations the USB device supports. If *DeviceDescriptor* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If the USB device descriptor is not found, then **EFI_NOT_FOUND** is returned. Otherwise, the device descriptor is returned in *DeviceDescriptor*, and **EFI_SUCCESS** is returned.

Status Code Returned

EFI_SUCCESS	The device descriptor was retrieved successfully.
EFI_INVALID_PARAMETER	DeviceDescriptor is NULL.
EFI_NOT_FOUND	The device descriptor was not found. The device may not be configured.

EFI_USB_IO_PROTOCOL.UsbGetConfigDescriptor()

Summary

Retrieves the USB Device Configuration Descriptor.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_CONFIG_DESCRIPTOR) (
    IN  EFI_USB_IO_PROTOCOL      *This,
    OUT EFI_USB_CONFIG_DESCRIPTOR *ConfigurationDescriptor
);
```

Parameters

This A pointer to the [EFI_USB_IO_PROTOCOL](#) instance. Type [EFI_USB_IO_PROTOCOL](#) is defined in [Section 16.2.4](#).

ConfigurationDescriptor A pointer to the caller allocated USB Active Configuration Descriptor. See “Related Definitions” for a detailed description.

Related Definitions

```
//
// See USB1.1 for detail description.
//
typedef struct {
    UINT8    Length;
    UINT8    DescriptorType;
    UINT16   TotalLength;
    UINT8    NumInterfaces;
    UINT8    ConfigurationValue;
    UINT8    Configuration;
    UINT8    Attributes;
    UINT8    MaxPower;
} EFI_USB_CONFIG_DESCRIPTOR;
```

Description

This function is used to retrieve the active configuration that the USB device is currently using. If *ConfigurationDescriptor* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If the USB controller does not contain an active configuration, then **EFI_NOT_FOUND** is returned. Otherwise, the active configuration is returned in *ConfigurationDescriptor*, and **EFI_SUCCESS** is returned.

Status Code Returned

EFI_SUCCESS	The active configuration descriptor was retrieved successfully.
EFI_INVALID_PARAMETER	ConfigurationDescriptor is NULL.

Unified Extensible Firmware Interface Specification

EFI_NOT_FOUND	An active configuration descriptor cannot be found. The device may not be configured.
---------------	---

EFI_USB_IO_PROTOCOL.UsbGetInterfaceDescriptor()

Summary

Retrieves the Interface Descriptor for a USB Device Controller. As stated earlier, an interface within a USB device is equivalently to a USB Controller within the current configuration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_INTERFACE_DESCRIPTOR) (
    IN  EFI_USB_IO_PROTOCOL          *This,
    OUT EFI_USB_INTERFACE_DESCRIPTOR *InterfaceDescriptor
);
```

Parameters

This A pointer to the [EFI_USB_IO_PROTOCOL](#) instance. Type [EFI_USB_IO_PROTOCOL](#) is defined in [Section 16.2.4](#).

InterfaceDescriptor A pointer to the caller allocated USB Interface Descriptor within the configuration setting. See “Related Definitions” for a detailed description.

Related Definitions

```
//
// See USB1.1 for detail description.
//
typedef struct {
    UINT8  Length;
    UINT8  DescriptorType;
    UINT8  InterfaceNumber;
    UINT8  AlternateSetting;
    UINT8  NumEndpoints;
    UINT8  InterfaceClass;
    UINT8  InterfaceSubClass;
    UINT8  InterfaceProtocol;
    UINT8  Interface;
} EFI_USB_INTERFACE_DESCRIPTOR;
```

Description

This function is used to retrieve the interface descriptor for the USB controller. If *InterfaceDescriptor* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If the USB controller does not contain an interface descriptor, then **EFI_NOT_FOUND** is returned. Otherwise, the interface descriptor is returned in *InterfaceDescriptor*, and **EFI_SUCCESS** is returned.

Status Code Returned

EFI_SUCCESS	The interface descriptor retrieved successfully.
-------------	--

Unified Extensible Firmware Interface Specification

EFI_INVALID_PARAMETER	InterfaceDescriptor is NULL .
EFI_NOT_FOUND	The interface descriptor cannot be found. The device may not be correctly configured.

EFI_USB_IO_PROTOCOL.UsbGetEndpointDescriptor()

Summary

Retrieves an Endpoint Descriptor within a USB Controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_ENDPOINT_DESCRIPTOR) (
    IN    EFI_USB_IO_PROTOCOL      *This,
    IN    UINT8                    EndpointIndex,
    OUT   EFI_USB_ENDPOINT_DESCRIPTOR *EndpointDescriptor
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB_IO_PROTOCOL instance. Type EFI_USB_IO_PROTOCOL is defined in Section 16.2.4 .
<i>EndpointIndex</i>	Indicates which endpoint descriptor to retrieve. The valid range is 0..15.
<i>EndpointDescriptor</i>	A pointer to the caller allocated USB Endpoint Descriptor of a USB controller. See “Related Definitions” for a detailed description.

Related Definitions

```
//
// See USB1.1 for detail description.
//
typedef struct {
    UINT8    Length;
    UINT8    DescriptorType;
    UINT8    EndpointAddress;
    UINT8    Attributes;
    UINT16   MaxPacketSize;
    UINT8    Interval;
} EFI_USB_ENDPOINT_DESCRIPTOR;
```

Description

This function is used to retrieve an endpoint descriptor within a USB controller. If *EndpointIndex* is not in the range 0..15, then **EFI_INVALID_PARAMETER** is returned. If *EndpointDescriptor* is **NULL**, then **EFI_INVALID_PARAMETER** is returned. If the endpoint specified by *EndpointIndex* does not exist within the USB controller, then **EFI_NOT_FOUND** is returned. Otherwise, the endpoint descriptor is returned in *EndpointDescriptor*, and **EFI_SUCCESS** is returned.

Status Code Returned

EFI_SUCCESS	The endpoint descriptor was retrieved successfully.
EFI_INVALID_PARAMETER	<i>EndpointIndex</i> is not valid.
EFI_INVALID_PARAMETER	EndpointDescriptor is NULL .
EFI_NOT_FOUND	The endpoint descriptor cannot be found. The device may not be correctly configured.

Examples

The following code fragment shows how to retrieve all the endpoint descriptors from a USB controller.

```

EFI_USB_IO_PROTOCOL          *UsbIo;
EFI_USB_INTERFACE_DESCRIPTOR InterfaceDesc;
EFI_USB_ENDPOINT_DESCRIPTOR EndpointDesc;
UINTN                        Index;

Status = UsbIo->GetInterfaceDescriptor (
    UsbIo,
    &InterfaceDesc
);
. . .
for(Index = 0; Index < InterfaceDesc.NumEndpoints; Index++) {
    Status = UsbIo->GetEndpointDescriptor(
        UsbIo,
        Index,
        &EndpointDesc
    );
. . .
}

```

EFI_USB_IO_PROTOCOL.UsbGetStringDescriptor()

Summary

Retrieves a string stored in a USB Device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_STRING_DESCRIPTOR) (
    IN    EFI_USB_IO_PROTOCOL  *This,
    IN    UINT16                LangID,
    IN    UINT8                 StringID,
    OUT   CHAR16                **String
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB_IO_PROTOCOL instance. Type EFI_USB_IO_PROTOCOL is defined in Section 16.2.4 .
<i>LangID</i>	The Language ID for the string being retrieved. See the UsbGetSupportedLanguages () function description for a more detailed description.
<i>StringID</i>	The ID of the string being retrieved.
<i>String</i>	A pointer to a buffer allocated by this function with EFI_BOOT_SERVICES.AllocatePool () to store the string. If this function returns EFI_SUCCESS , it stores the string the caller wants to get. The caller should release the string buffer with EFI_BOOT_SERVICES.FreePool () after the string is not used any more.

Description

This function is used to retrieve strings stored in a USB device. The string to retrieve is identified by a language and an identifier. The language is specified by *LangID*, and the identifier is specified by *StringID*. If the string is found, it is returned in *String*, and [EFI_SUCCESS](#) is returned. If the string cannot be found, then [EFI_NOT_FOUND](#) is returned. The string buffer is allocated by this function with [AllocatePool \(\)](#). The caller is responsible for calling [FreePool \(\)](#) for *String* when it is no longer required.

Status Code Returned

EFI_SUCCESS	The string was retrieved successfully.
EFI_NOT_FOUND	The string specified by <i>LangID</i> and <i>StringID</i> was not found.
EFI_OUT_OF_RESOURCES	There are not enough resources to allocate the return buffer <i>String</i> .

EFI_USB_IO_PROTOCOL.UsbGetSupportedLanguages()

Summary

Retrieves all the language ID codes that the USB device supports.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_SUPPORTED_LANGUAGES) (
    IN  EFI_USB_IO_PROTOCOL  *This,
    OUT UINT16                **LangIDTable,
    OUT UINT16                *TableSize
);
```

Parameters

<i>This</i>	A pointer to the EFI_USB_IO_PROTOCOL instance. Type EFI_USB_IO_PROTOCOL is defined in Section 16.2.4 .
<i>LangIDTable</i>	Language ID for the string the caller wants to get. This is a 16-bit ID defined by Microsoft. This buffer pointer is allocated and maintained by the USB Bus Driver, the caller should not modify its contents.
<i>TableSize</i>	The size, in bytes, of the table <i>LangIDTable</i> .

Description

Retrieves all the language ID codes that the USB device supports.

Status Code Returned

EFI_SUCCESS	The support languages were retrieved successfully.
-------------	--

EFI_USB_IO_PROTOCOL.UsbPortReset()

Summary

Resets and reconfigures the USB controller. This function will work for all USB devices except USB Hub Controllers.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_PORT_RESET) (
    IN EFI_USB_IO_PROTOCOL *This
);
```

Parameters

This A pointer to the [EFI_USB_IO_PROTOCOL](#) instance. Type [EFI_USB_IO_PROTOCOL](#) is defined in [Section 16.2.4](#).

Description

This function provides a reset mechanism by sending a RESET signal from the parent hub port. A reconfiguration process will happen (that includes setting the address and setting the configuration). This reset function does not change the bus topology. A USB hub controller cannot be reset using this function, because it would impact the downstream USB devices. So if the controller is a USB hub controller, then [EFI_INVALID_PARAMETER](#) is returned.

Status Code Returned

EFI_SUCCESS	The USB controller was reset.
EFI_INVALID_PARAMETER	If the controller specified by <i>This</i> is a USB hub.
EFI_DEVICE_ERROR	An error occurred during the reconfiguration process.

16.3 USB Function Protocol

This section describes the USB Function Protocol, enabling a USB Function device with a UEFI driver that implements the protocol to communicate with a a USB Host device.

The USB Function Protocol provides an I/O abstraction for a USB Controller operating in Function mode (also commonly referred to as Device, Peripheral, or Target mode) and the mechanisms by which the USB Function can communicate with the USB Host. It is used by other UEFI drivers or applications to perform data transactions and basic USB controller management over a USB Function port.

This simple protocol only supports USB 2.0 bulk transfers on systems with a single configuration and a single interface. It does not support isochronous or interrupt transfers, alternate interfaces, or USB 3.0 functionality. Future revisions of this protocol may support these or additional features.

EFI_USBFN_IO_PROTOCOL

Summary

Provides basic data transactions and basic USB controller management for a USB Function port.

GUID

```
// {32D2963A-FE5D-4f30-B633-6E5DC55803CC}
#define EFI_USBFN_IO_PROTOCOL_GUID \
    {0x32d2963a, 0xfe5d, 0x4f30,\
     0xb6, 0x33, 0x6e, 0x5d, 0xc5, 0x58, 0x3, 0xcc};
```

Revision Number

```
#define EFI_USBFN_IO_PROTOCOL_REVISION    0x00010001
```

Protocol Interface Structure

```
typedef struct _EFI_USBFN_IO_PROTOCOL {
    UINT32                                Revision;
    EFI_USBFN_IO_DETECT_PORT              DetectPort;
    EFI_USBFN_IO_CONFIGURE_ENABLE_ENDPOINTS \
                                           ConfigureEnableEndpoints;
    EFI_USBFN_IO_GET_ENDPOINT_MAXPACKET_SIZE \
                                           GetEndpointMaxPacketSize;
    EFI_USBFN_IO_GET_DEVICE_INFO          GetDeviceInfo;
    EFI_USBFN_IO_GET_VENDOR_ID_PRODUCT_ID \
                                           GetVendorIdProductId;
    EFI_USBFN_IO_ABORT_TRANSFER           AbortTransfer;
    EFI_USBFN_IO_GET_ENDPOINT_STALL_STATE \
                                           GetEndpointStallState;
    EFI_USBFN_IO_SET_ENDPOINT_STALL_STATE \
                                           SetEndpointStallState;
    EFI_USBFN_IO_EVENTHANDLER             EventHandler;
    EFI_USBFN_IO_TRANSFER                 Transfer;
    EFI_USBFN_IO_GET_MAXTRANSFER_SIZE    \
                                           GetMaxTransferSize;
    EFI_USBFN_IO_ALLOCATE_TRANSFER_BUFFER AllocateTransferBuffer;
    EFI_USBFN_IO_FREE_TRANSFER_BUFFER     FreeTransferBuffer;
    EFI_USBFN_IO_START_CONTROLLER         StartController;
    EFI_USBFN_IO_STOP_CONTROLLER          StopController;
    EFI_USBFN_IO_SET_ENDPOINT_POLICY      SetEndpointPolicy;
    EFI_USBFN_IO_GET_ENDPOINT_POLICY     GetEndpointPolicy;
} EFI_USBFN_IO_PROTOCOL;
```

Parameters

Revision

The revision to which the **EFI_USBFN_IO_PROTOCOL** adheres. All future revisions must be backwards compatible. If a future version is not backwards compatible, a different GUID must be used.

<i>DetectPort</i>	Returns information about the USB port type. See EFI USBFN IO PROTOCOL.DetectPort() , "Related Definitions" for more details.
<i>ConfigureEnableEndpoints</i>	Initializes all endpoints based on supplied device and configuration descriptors. Enables the device by setting the run/stop bit.
<i>GetEndpointMaxPacketSize</i>	Returns the maximum packet size of the specified endpoint.
<i>GetDeviceInfo</i>	Returns device specific information based on the supplied identifier as a Unicode string.
<i>GetVendorIdProductId</i>	Returns the vendor-id and product-id of the device.
<i>AbortTransfer</i>	Aborts the transfer on the specified endpoint.
<i>GetEndpointStallState</i>	Returns the stall state on the specified endpoint.
<i>SetEndpointStallState</i>	Sets or clears the stall state on the specified endpoint.
<i>EventHandler</i>	This function is called repeatedly to get information on USB bus states, receive-completion and transmit-completion events on the endpoints, and notification on setup packet on endpoint 0.
<i>Transfer</i>	This function handles transferring data to or from the host on the specified endpoint, depending on the direction specified.
<i>GetMaxTransferSize</i>	The maximum supported transfer size in bytes.
<i>AllocateTransferBuffer</i>	Allocates a transfer buffer of the specified size that satisfies the controller requirements.
<i>FreeTransferBuffer</i>	Deallocates the memory allocated for the transfer buffer by EFI USBFN IO PROTOCOL.AllocateTransferBuffer() function.
<i>StartController</i>	This function initializes the hardware and the internal data structures. The port must not be activated by this function.
<i>StopController</i>	This function disables the device by deactivating the port.
<i>SetEndpointPolicy</i>	This function sets the configuration policy for the specified non-control endpoint. There are a few calling restrictions for this function. See the EFI USBFN IO PROTOCOL.SetEndpointPolicy() function definition for more details.
<i>GetEndpointPolicy</i>	This functions retrieves the configuration policy for the specified non-control endpoint.

Description

This protocol provides basic data transactions and USB controller management for a USB Function port. It provides a lightweight communication mechanism between a USB Host and a USB Function in the UEFI environment.

Like other UEFI device drivers, the entry point for a USB function driver attaches **EFI_DRIVER_BINDING_PROTOCOL** to image handle of **EFI_USBFN_IO_PROTOCOL** driver.

The driver binding protocol contains three services, *Supported*, *Start* and *Stop*.

The *Supported* function must test to see if this driver supports a given controller.

The *Start* function must supply power to the USB controller if needed, initialize hardware and internal data structures, and then return. The port must not be activated by this function.

The *Stop* function must disable the USB controller and power it off if needed.

EFI_USBFN_IO_PROTOCOL.DetectPort()

Summary

Returns information about what USB port type was attached.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_DETECT_PORT) (
    IN EFI_USBFN_IO_PROTOCOL *This,
    OUT EFI_USBFN_PORT_TYPE *PortType
);
```

Parameters

This A pointer to the **EFI_USBFN_IO_PROTOCOL** instance.

PortType Returns the USB port type. Refer to the Related Definitions.

for this function below for details.

Description

Returns information about the USB port type attached. Refer to the "Related Definitions" below for further details.

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request or there is no USB port attached to the device.

Related Definitions

```
typedef enum _EFI_USBFN_PORT_TYPE {
    EfiUsbUnknownPort = 0,
    EfiUsbStandardDownstreamPort,
    EfiUsbChargingDownstreamPort,
    EfiUsbDedicatedChargingPort,
    EfiUsbInvalidDedicatedChargingPort
} EFI_USBFN_PORT_TYPE;
```

Unknown Port Driver internal default port type, this is never returned by the driver with a success status code.

Standard Downstream Port Standard USB host; refer to *USB Battery Charging Specification, Revision 1.2* in [Section Q.1](#) for details and the link.

Charging Downstream Port

Standard USB host with special charging properties; refer to *USB Battery Charging Specification, Revision 1.2* in [Section Q.1](#) for the details and link.

Dedicated Charging Port

A wall-charger, not USB host; refer to *USB Battery Charging Specification, Revision 1.2*, [Section Q.1](#) for details and the link.

Invalid Dedicated Charging Port –

Neither a USB host nor a dedicated charging port as defined by the *USB Battery Charging Specification, Revision 1.2*. (See [Section Q.1](#) for details and the link.) An example is a USB charger that raises the voltages on D+/D-, causing the charger to look like an SDP even though it will never issue a setup packet to the upstream facing port.

EFI_USBFN_IO_PROTOCOL.ConfigureEnableEndpoints()

Summary

Configures endpoints based on supplied device and configuration descriptors.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_CONFIGURE_ENABLE_ENDPOINTS) (
    IN EFI_USBFN_IO_PROTOCOL          *This,
    IN EFI_USB_DEVICE_INFO            *DeviceInfo
);
```

Parameters

This A pointer to the **EFI_USBFN_IO_PROTOCOL** instance.

DeviceInfo A pointer to **EFI_USB_DEVICE_INFO** instance. Refer to the "Related Definitions" for this function below for details.

Description

Assuming that the hardware has already been initialized, this function configures the endpoints using the device information supplied by *DeviceInfo*, activates the port, and starts receiving USB events.

This function must ignore the **bMaxPacketSize0** field of the *Standard Device Descriptor* and the **wMaxPacketSize** field of the *Standard Endpoint Descriptor* that are made available through *DeviceInfo*.

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.
EFI_OUT_OF_RESOURCES	The request could not be completed due to lack of resources.

Related Definitions

```
typedef struct {
    EFI_USB_INTERFACE_DESCRIPTOR *InterfaceDescriptor;
    EFI_USB_ENDPOINT_DESCRIPTOR **EndpointDescriptorTable;
} EFI_USB_INTERFACE_INFO;
```

```
typedef struct {
    EFI_USB_CONFIG_DESCRIPTOR          *ConfigDescriptor;
    EFI_USB_INTERFACE_INFO             **InterfaceInfoTable;
} EFI_USB_CONFIG_INFO;

typedef struct {
    EFI_USB_DEVICE_DESCRIPTOR          *DeviceDescriptor;
    EFI_USB_CONFIG_INFO                **ConfigInfoTable;
} EFI_USB_DEVICE_INFO;
```

USB_DEVICE_DESCRIPTOR, USB_CONFIG_DESCRIPTOR, USB_INTERFACE_DESCRIPTOR, and USB_ENDPOINT_DESCRIPTOR are defined in [Section 16.2.4](#).

EFI_USBFN_IO_PROTOCOL.GetEndpointMaxPacketSize()

Summary

Returns the maximum packet size of the specified endpoint type for the supplied bus speed.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_GET_ENDPOINT_MAXPACKET_SIZE) (
    IN EFI_USBFN_IO_PROTOCOL      *This,
    IN EFI_USB_ENDPOINT_TYPE      EndpointType,
    IN EFI_USB_BUS_SPEED          BusSpeed,
    OUT UINT16                    *MaxPacketSize
);
```

Parameters

<i>This</i>	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
<i>EndpointType</i>	Endpoint type as defined as EFI_USB_ENDPOINT_TYPE in the "Related Definitions" for this function below for details.
<i>BusSpeed</i>	Bus speed as defined as EFI_USB_BUS_SPEED in the "Related Definitions" for the <i>EventHandle</i> function for details.
<i>MaxPacketSize</i>	The maximum packet size, in bytes, of the specified endpoint type.

Description

Returns the maximum packet size of the specified endpoint type for the supplied bus speed. If the *BusSpeed* is *UsbBusSpeedUnknown*, the maximum speed the underlying controller supports is assumed.

This protocol currently does not support isochronous or interrupt transfers. Future revisions of this protocol may eventually support it.

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

Related Definitions

```
typedef enum _EFI_USB_ENDPOINT_TYPE
{
    UsbEndpointControl = 0x00,
    // UsbEndpointIsochronous = 0x01,
    UsbEndpointBulk = 0x02,
```

```
// UsbEndpointInterrupt = 0x03  
} EFI_USB_ENDPOINT_TYPE;
```

EFI_USBFN_IO_PROTOCOL.GetDeviceInfo()

Summary

Returns device specific information based on the supplied identifier as a Unicode string.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_GET_DEVICE_INFO) (
    IN EFI_USBFN_IO_PROTOCOL      *This,
    IN EFI_USBFN_DEVICE_INFO_ID   Id,
    IN OUT UINTN                  *BufferSize,
    OUT VOID                       *Buffer OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
<i>Id</i>	The requested information id. Refer to the "Related Definitions" for this function below for details.
<i>BufferSize</i>	On input, the size of the <i>Buffer</i> in bytes. On output, the amount of data returned in <i>Buffer</i> in bytes.
<i>Buffer</i>	A pointer to a buffer to return the requested information as a Unicode string.

Description

Returns device specific information based on the supplied identifier as a Unicode string. If the supplied *Buffer* isn't large enough, or is NULL, the method fails with **EFI_BUFFER_TOO_SMALL** and the required size is returned through *BufferSize*. All returned strings are in Unicode format.

An *Id* of *EfiUsbDeviceInfoUnknown* is treated as an invalid parameter.

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.
EFI_BUFFER_TOO_SMALL	Supplied buffer isn't large enough to hold the request string.

Related Definitions

```
typedef enum _EFI_USBFN_DEVICE_INFO_ID
{
    EfiUsbDeviceInfoUnknown = 0,
    EfiUsbDeviceInfoSerialNumber,
}
```

```
    EfiUsbDeviceInfoManufacturerName,  
    EfiUsbDeviceInfoProductName  
} EFI_USBFN_DEVICE_INFO_ID;
```

EFI_USBFN_IO_PROTOCOL.GetVendorIdProductId()

Summary

Returns the vendor-id and product-id of the device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_GET_VENDOR_ID_PRODUCT_ID) (
    IN EFI_USBFN_IO_PROTOCOL      *This,
    OUT UINT16                    *Vid,
    OUT UINT16                    *Pid
);
```

Parameters

<i>This</i>	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
<i>Vid</i>	Returned vendor-id of the device.
<i>Pid</i>	Returned product-id of the device.

Description

Returns vendor-id and product-id of the device.

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_NOT_FOUND	Unable to return the vendor-id or the product-id

Related Definitions

Vendor IDs (VIDs) are 16-bit numbers that represent the device's vendor company and are assigned and maintained by the USB-IF. Product IDs (PIDs) are 16-bit numbers assigned by each vendor to the device.

EFI_USBFN_IO_PROTOCOL.AbortTransfer()

Summary

Aborts the transfer on the specified endpoint.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_ABORT_TRANSFER) (
    IN EFI_USBFN_IO_PROTOCOL          *This,
    IN UINT8                          EndpointIndex,
    IN EFI_USBFN_ENDPOINT_DIRECTION  Direction
);
```

Parameters

<i>This</i>	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
<i>EndpointIndex</i>	Indicates the endpoint on which the ongoing transfer needs to be canceled.
<i>Direction</i>	Direction of the endpoint. Refer to the "Related Definitions" for this function (below) for details.

Description

Aborts the transfer on the specified endpoint. This function should fail with **EFI_INVALID_PARAMETER** if the specified direction is incorrect for the endpoint.

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

Related Definitions

```
typedef enum _EFI_USBFN_ENDPOINT_DIRECTION
{
    EfiUsbEndpointDirectionHostOut = 0,
    EfiUsbEndpointDirectionHostIn,
    EfiUsbEndpointDirectionDeviceTx =
EfiUsbEndpointDirectionHostIn,
    EfiUsbEndpointDirectionDeviceRx =
EfiUsbEndpointDirectionHostOut
} EFI_USBFN_ENDPOINT_DIRECTION;
```

EFI_USBFN_IO_PROTOCOL.GetEndpointStallState()

Summary

Returns the stall state on the specified endpoint.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_GET_ENDPOINT_STALL_STATE) (
    IN EFI_USBFN_IO_PROTOCOL      *This,
    IN UINT8                      EndpointIndex,
    IN EFI_USBFN_ENDPOINT_DIRECTION Direction,
    IN OUT BOOLEAN                *State
);
```

Parameters

<i>This</i>	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
<i>EndpointIndex</i>	Indicates the endpoint.
<i>Direction</i>	Direction of the endpoint. Refer to the "Related Definitions" for EFI_USBFN_IO_PROTOCOL.AbortTransfer() for details.
<i>State</i>	Boolean, true value indicates that the endpoint is in a stalled state, false otherwise.

Description

Returns the stall state on the specified endpoint. This function would fail with **EFI_INVALID_PARAMETER** if the specified direction is incorrect for the endpoint.

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

EFI_USBFN_IO_PROTOCOL.SetEndpointStallState()

Summary

Sets or clears the stall state on the specified endpoint.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_SET_ENDPOINT_STALL_STATE) (
    IN EFI_USBFN_IO_PROTOCOL      *This,
    IN UINT8                      EndpointIndex,
    IN EFI_USBFN_ENDPOINT_DIRECTION Direction,
    IN BOOLEAN                    State
);
```

Parameters

<i>This</i>	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
<i>EndpointIndex</i>	Indicates the endpoint.
<i>Direction</i>	Direction of the endpoint. Refer to the "Related Definitions" for the EFI_USBFN_IO_PROTOCOL.AbortTransfer() function for details.
<i>State</i>	Requested stall state on the specified endpoint. True value causes the endpoint to stall; false value clears an existing stall.

Description

Sets or clears the stall state on the specified endpoint. This function would fail with **EFI_INVALID_PARAMETER** if the specified direction is incorrect for the endpoint.

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

EFI_USBFN_IO_PROTOCOL.EventHandler()

Summary

This function is called repeatedly to get information on USB bus states, receive-completion and transmit-completion events on the endpoints, and notification on setup packet on endpoint 0.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_EVENTHANDLER) (
    IN EFI_USBFN_IO_PROTOCOL          *This,
    OUT EFI_USBFN_MESSAGE             *Message,
    IN OUT UINTN                      *PayloadSize,
    OUT EFI_USBFN_MESSAGE_PAYLOAD     *Payload
);
```

Parameters

<i>This</i>	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
<i>Message</i>	Indicates the event that initiated this notification. Refer to the "Related Definitions" for this function (below) for all possible types.
<i>PayloadSize</i>	On input, the size of the memory pointed by <i>Payload</i> . On output, the amount of data returned in <i>Payload</i> .
<i>Payload</i>	A pointer to EFI_USBFN_MESSAGE_PAYLOAD instance to return additional payload for current message. Refer to the "Related Definitions" for this function (below) for details on the type.

Description

This function is called repeatedly to get information on USB bus states, receive-completion and transmit-completion events on the endpoints, and notification on setup packet on endpoint 0. A class driver must call **EFI_USBFN_IO_PROTOCOL.EventHandler()** repeatedly to receive updates on the transfer status and number of bytes transferred on various endpoints. Refer to [Figure 54](#) for details.

A few messages have an associated payload that is returned in the supplied buffer. The following table describes various messages and their payload:

Message	Payload	Description
EfiUsbMsgSetupPacket	EFI_USB_DEVICE_REQUE ST	SETUP packet was received.

EfiUsbMsgEndpointStatusChangedRx	EFI_USBFN_TRANSFER_RESULT	Some of the requested data has been transmitted to the host. It is the responsibility of the class driver to determine if any remaining data needs to be re-sent. The <i>Buffer</i> supplied to EFI USBFN IO PROTOCOL .Transfer() must be same as the <i>Buffer</i> field of the payload.
EfiUsbMsgEndpointStatusChangedTx	EFI_USBFN_TRANSFER_RESULT	Some of the requested data has been received from the host. It is the responsibility of the class driver to determine if it needs to wait for any remaining data. The <i>Buffer</i> supplied to EFI USBFN IO PROTOCOL .Transfer() must be same as the <i>Buffer</i> field of the payload.
EfiUsbMsgBusEventReset	None	A RESET bus event was signaled.
EfiUsbMsgBusEventDetach	None	A DETACH bus event was signaled.
EfiUsbMsgBusEventAttach	None	An ATTACH bus event was signaled.
EfiUsbMsgBusEventSuspend	None	A SUSPEND bus event was signaled.
EfiUsbMsgBusEventResume	None	A RESUME bus event was signaled.
EfiUsbMsgBusEventSpeed	EFI_USB_BUS_SPEED	A Bus speed update was signaled.

Table 139. Payload-associated Messages and Descriptions

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.
EFI_BUFFER_TOO_SMALL	The Supplied buffer is not large enough to hold the message payload.

Related Definitions

    EFI_USB_BUS_SPEED                  uds;
} EFI_USBFN_MESSAGE_PAYLOAD;

```

EFI_USBFN_IO_PROTOCOL.Transfer()

Summary

This function handles transferring data to or from the host on the specified endpoint, depending on the direction specified.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USBFN_IO_TRANSFER) (
    IN EFI_USBFN_IO_PROTOCOL          *This,
    IN UINT8                          EndpointIndex,
    IN EFI_USBFN_ENDPOINT_DIRECTION  Direction,
    IN OUT UINTN                       *BufferSize,
    IN OUT VOID                        *Buffer
);
```

Parameters

This	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
EndpointIndex	Indicates the endpoint on which TX or RX transfer needs to take place.
Direction	Direction of the endpoint. Refer to the "Related Definitions" of the EFI_USBFN_IO_PROTOCOL.AbortTransfer() function for details.
BufferSize	If <i>Direction</i> is EfiUsbEndpointDirectionDeviceRx: On input, the size of the <i>Buffer</i> in bytes. On output, the amount of data returned in <i>Buffer</i> in bytes. If <i>Direction</i> is EfiUsbEndpointDirectionDeviceTx: On input, the size of the <i>Buffer</i> in bytes. On output, the amount of data transmitted in bytes.
Buffer	If <i>Direction</i> is EfiUsbEndpointDirectionDeviceRx: The <i>Buffer</i> to return the received data. If <i>Direction</i> is EfiUsbEndpointDirectionDeviceTx: The Buffer that contains the data to be transmitted.

Note: This buffer is allocated and freed using the [EFI_USBFN_IO_PROTOCOL.AbortTransfer\(\)](#) and [EFI_USBFN_IO_PROTOCOL.FreeTransferBuffer\(\)](#) functions. The caller of this function must not free or reuse the buffer until EfiUsbMsgEndpointStatusChangedRx or EfiUsbMsgEndpointStatusChangedTx message was received along with the address of the transfer buffer as part of the message payload. Refer to the function definition for [EFI_USBFN_IO_PROTOCOL.EventHandler\(\)](#) for more information on various messages and their payloads.

Description

This function handles transferring data to or from the host on the specified endpoint, depending on the direction specified.

Direction	Description
EfiUsbEndpointDirectionDeviceTx	Start a transmit transfer on the specified endpoint and return immediately.
EfiUsbEndpointDirectionDeviceRx	Start a receive transfer on the specified endpoint and return immediately with available data.

A class driver must call [EFI USBFN IO PROTOCOL.EventHandler\(\)](#) repeatedly to receive updates on the transfer status and the number of bytes transferred on various endpoints. Upon an update of the transfer status, the *Buffer* field of the **EFI_USBFN_TRANSFER_RESULT** structure (as described in the function description for [EFI USBFN IO PROTOCOL.EventHandler\(\)](#)) must be initialized with the *Buffer* pointer that was supplied to this method.

The overview of the call sequence is illustrated in the [Figure 54](#).

This function should fail with **EFI_INVALID_PARAMETER** if the specified direction is incorrect for the endpoint.

Status codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

EFI_USBFN_IO_PROTOCOL.GetMaxTransferSize()

Summary

Returns the maximum supported transfer size.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_GET_MAXTRANSFER_SIZE) (
    IN EFI_USBFN_IO_PROTOCOL      *This,
    OUT UINTN                      *MaxTransferSize
);
```

Parameters

This A pointer to the **EFI_USBFN_IO_PROTOCOL** instance.

MaxTransferSize The maximum supported transfer size, in bytes.

Description

Returns the maximum number of bytes that the underlying controller can accommodate in a single transfer.

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

EFI_USBFN_IO_PROTOCOL.AllocateTransferBuffer()

Summary

Allocates a transfer buffer of the specified size that satisfies the controller requirements.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_ALLOCATE_TRANSFER_BUFFER) (
    IN EFI_USBFN_IO_PROTOCOL    *This,
    IN UINTN                     Size,
    OUT VOID                     **Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
<i>Size</i>	The number of bytes to allocate for the transfer buffer.
<i>Buffer</i>	A pointer to a pointer to the allocated buffer if the call succeeds; undefined otherwise.

Description

The **AllocateTransferBuffer()** function allocates a memory region of *Size* bytes and returns the address of the allocated memory that satisfies the underlying controller requirements in the location referenced by *Buffer*.

The allocated transfer buffer must be freed using a matching call to [EFI_USBFN_IO_PROTOCOL.FreeTransferBuffer\(\)](#) function.

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_OUT_OF_RESOURCES	The requested transfer buffer could not be allocated.

EFI_USBFN_IO_PROTOCOL.FreeTransferBuffer()

Summary

Deallocates the memory allocated for the transfer buffer by the [EFI_USBFN_IO_PROTOCOL.AllocateTransferBuffer\(\)](#) function.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_FREE_TRANSFER_BUFFER) (
    IN EFI_USBFN_IO_PROTOCOL    *This,
    IN VOID                     *Buffer
);
```

Parameters

This A pointer to the **EFI_USBFN_IO_PROTOCOL** instance.

Buffer A pointer to the transfer buffer to deallocate.

Description

The [EFI_USBFN_IO_PROTOCOL.FreeTransferBuffer\(\)](#) function deallocates the memory specified by *Buffer*. The Buffer that is freed must have been allocated by [EFI_USBFN_IO_PROTOCOL.AllocateTransferBuffer\(\)](#).

Status Codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.

EFI_USBFN_IO_PROTOCOL.StartController()

Summary

This function supplies power to the USB controller if needed and initializes the hardware and the internal data structures. The port must not be activated by this function

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_START_CONTROLLER) (
    IN EFI_USBFN_IO_PROTOCOL *This
);
```

Parameters

This A pointer to the **EFI_USBFN_IO_PROTOCOL** instance.

Description

This function starts the hardware by supplying power to the USB controller if needed, and initializing the hardware and internal data structures. The port must not be activated by this function.

Status codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.

EFI_USBFN_IO_PROTOCOL.StopController()

Summary

This function stops the USB hardware device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_STOP_CONTROLLER) (
    IN EFI_USBFN_IO_PROTOCOL *This
);
```

Parameters

This A pointer to the **EFI_USBFN_IO_PROTOCOL** instance.

Description

This function stops the USB hardware device

Status codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.

EFI_USBFN_IO_PROTOCOL.SetEndpointPolicy()

Summary

This function sets the configuration policy for the specified non-control endpoint. Refer to the description for calling restrictions.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_SET_ENDPOINT_POLICY) (
    IN EFI_USBFN_IO_PROTOCOL      *This,
    IN UINT8                      EndpointIndex
    IN EFI_USBFN_ENDPOINT_DIRECTION Direction,
    IN EFI_USBFN_POLICY_TYPE      PolicyType,
    IN UINTN                      BufferSize,
    IN VOID                       *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
<i>EndpointIndex</i>	Indicates the non-control endpoint for which the policy needs to be set.
<i>Direction</i>	Direction of the endpoint. Refer to the "Related Definitions" for the EFI_USBFN_IO_PROTOCOL.AbortTransfer() function for details.
<i>PolicyType</i>	Policy type the user is trying to set for the specified non-control endpoint. Refer to "Related Definitions" for this function below for details.
<i>BufferSize</i>	The size of the <i>Buffer</i> in bytes.
<i>Buffer</i>	The new value for the policy parameter that <i>PolicyType</i> specifies. Refer to "Related Definitions" for this function below for details.

Description

This function sets the configuration policy for the specified non-control endpoint. This function can only be called before [EFI_USBFN_IO_PROTOCOL.StartController\(\)](#) or after [EFI_USBFN_IO_PROTOCOL.StopController\(\)](#) has been called.

Status codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_UNSUPPORTED	Changing this policy value is not supported.

Related Definitions

```
typedef enum _EFI_USBFN_POLICY_TYPE
{
    EfiUsbPolicyUndefined = 0,
    EfiUsbPolicyMaxTransactionSize,
    EfiUsbPolicyZeroLengthTerminationSupport,
    EfiUsbPolicyZeroLengthTermination
} EFI_USBFN_POLICY_TYPE;
```

EfiUsbPolicyUndefined

Invalid policy value that must never be used across driver boundary. If used, the function must not return a success status code.

EfiUsbPolicyMaxTransactionSize

EfiUsbPolicyMaxTransactionSize is only used with [EFI_USBFN_IO_PROTOCOL.GetEndpointPolicy\(\)](#). It provides the size of the largest single transaction (delivery of service to an endpoint) supported by a controller. It must be greater than or equal to the maximum transfer size that can be retrieved by calling [EFI_USBFN_IO_PROTOCOL.GetMaxTransferSize\(\)](#).

	GetEndpointPolicy	SetEndpointPolicy
BufferSize	4 bytes, sizeof(UINT32)	Not applicable
Return Status	EFI_STATUS	EFI_UNSUPPORTED

EfiUsbPolicyZeroLengthTerminationSupport

EfiUsbPolicyZeroLengthTerminationSupport is only used with [EFI_USBFN_IO_PROTOCOL.GetEndpointPolicy\(\)](#). It is TRUE if the USB controller is capable of automatically handling zero length packets when the transfer size is a multiple of USB maximum packet size and FALSE if it is not supported by the controller.

	GetEndpointPolicy	SetEndpointPolicy
BufferSize	1 byte, sizeof(BOOLEAN)	Not applicable
Return Status	EFI_STATUS	EFI_UNSUPPORTED

EfiUsbPolicyZeroLengthTermination

When used with [EFI USBFN IO PROTOCOL.GetEndpointPolicy\(\)](#), a TRUE value is returned if the USB controller hardware is configured to automatically handle zero length packets when the transfer size is a multiple of USB maximum packet size; a FALSE value is returned if the controller hardware is not configured to do this.

Using [EFI USBFN IO PROTOCOL.SetEndpointPolicy\(\)](#) to set the EfiUsbPolicyZeroLengthTermination policy is only applicable to USB controller hardware capable of supporting automatic zero length packet termination. When this value is set to TRUE, the controller must be configured to handle zero length termination for the specified endpoint. When this value is set to FALSE, the controller must be configured to not handle zero length termination for the specified endpoint.

The USB controller’s default policy must not enable automatic zero length packet termination, even if the hardware is capable of supporting it.

	GetEndpointPolicy	SetEndpointPolicy
BufferSize	1 byte, sizeof (BOOLEAN)	1 byte, sizeof (BOOLEAN)
Return Status	EFI_STATUS	EFI_STATUS

EFI_USBFN_IO_PROTOCOL.GetEndpointPolicy()

Summary

This function retrieves the configuration policy for the specified non-control endpoint. There are no associated calling restrictions for this function.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_GET_ENDPOINT_POLICY) (
    IN EFI_USBFN_IO_PROTOCOL      *This,
    IN UINT8                      EndpointIndex
    IN EFI_USBFN_ENDPOINT_DIRECTION Direction,
    IN EFI_USBFN_POLICY_TYPE      PolicyType,
    IN OUT UINTN                  *BufferSize,
    IN OUT VOID                   *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_USBFN_IO_PROTOCOL instance.
<i>EndpointIndex</i>	Indicates the non-control endpoint for which the policy needs to be set.
<i>Direction</i>	Direction of the endpoint. Refer to the "Related Definitions" for the EFI_USBFN_IO_PROTOCOL.AbortTransfer() function for details.
<i>PolicyType</i>	Policy type the user is trying to retrieve for the specified non-control endpoint. Refer to the "Related Definitions" for the EFI_USBFN_IO_PROTOCOL.SetEndpointPolicy() function for details.
<i>BufferSize</i>	On input, the size of <i>Buffer</i> in bytes. On output, the amount of data returned in <i>Buffer</i> in bytes.
<i>Buffer</i>	A pointer to a buffer to return requested endpoint policy value. Refer to the "Related Definitions" for the EFI_USBFN_IO_PROTOCOL.SetEndpointPolicy() function for size requirements of various policy types.

Description

This function retrieves the configuration policy for the specified non-control endpoint. This function has no calling restrictions.

Status codes

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.

EFI_UNSUPPORTED	The specified policy value is not supported.
EFI_BUFFER_TOO_SMALL	Supplied buffer is not large enough to hold requested policy value.

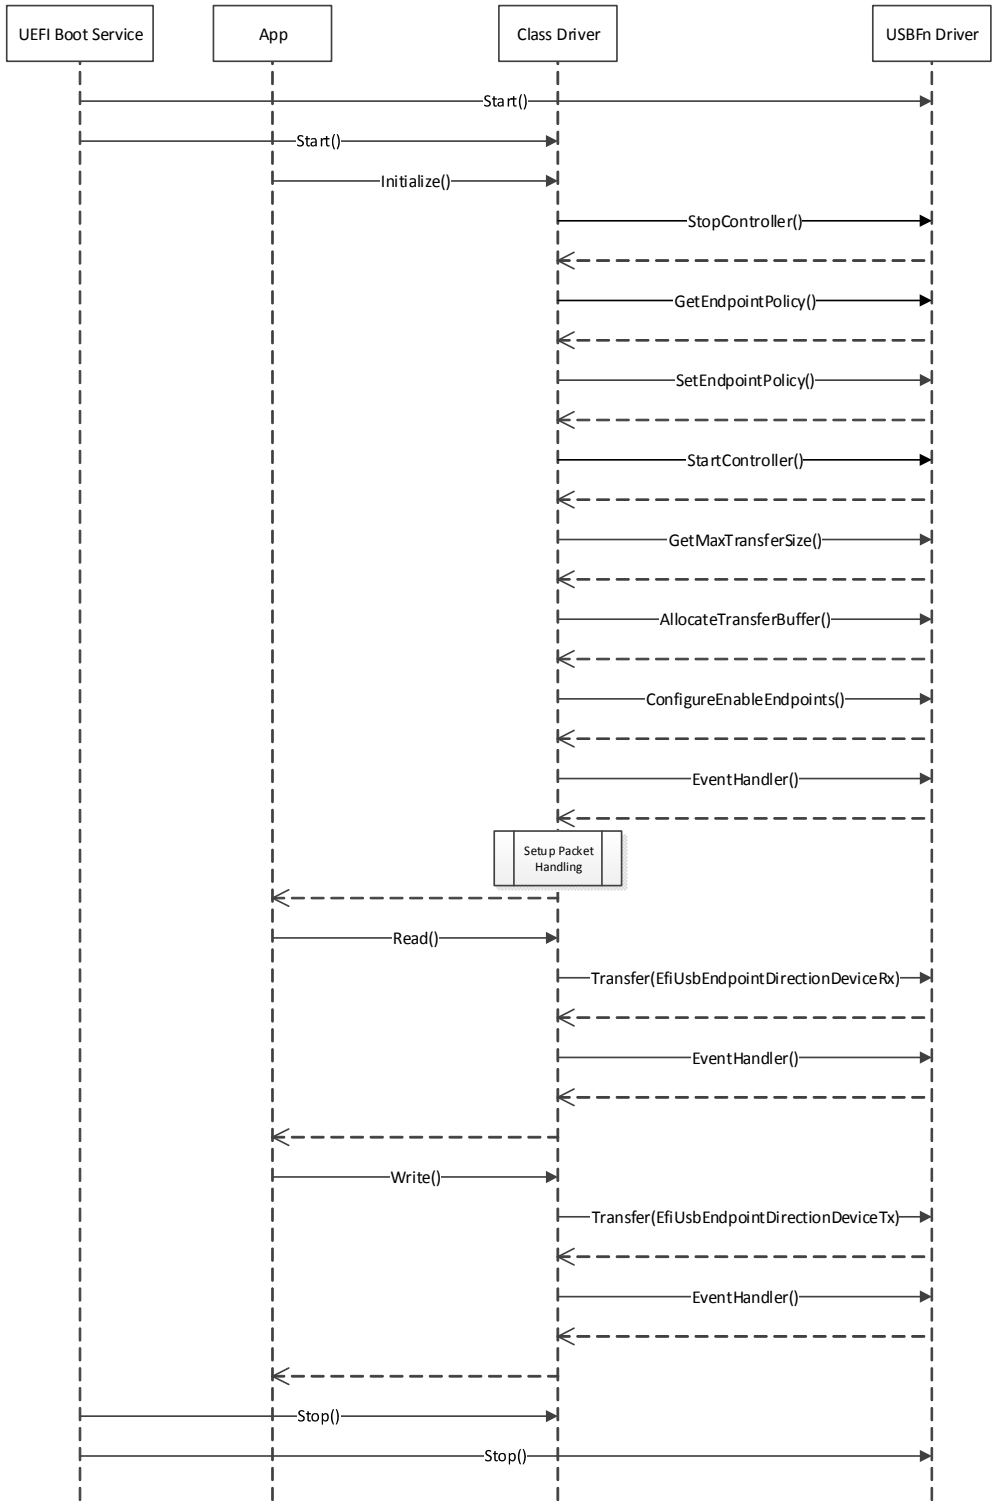

Figure 54. Sequence of Operations with Endpoint Policy Changes

Protocols — Debugger Support

This chapter describes a minimal set of protocols and associated data structures necessary to enable the creation of source level debuggers for EFI. It does not fully define a debugger design. Using the services described in this document, it should also be possible to implement a variety of debugger solutions.

17.1 Overview

Efficient UEFI driver and application development requires the availability of source level debugging facilities. Although completely on-target debuggers are clearly possible, UEFI debuggers are generally expected to be remotely hosted. That is to say, the debugger itself will be split between two machines, which are the host and target. A majority of debugger code runs on the host that is typically responsible for disassembly, symbol management, source display, and user interface. Similarly, a smaller piece of code runs on the target that establishes the communication to the host and proxies requests from the host. The on-target code is known as the “debug agent.”

The debug agent design is subdivided further into two parts, which are the processor/platform abstraction and the debugger host specific communication grammar. This specification describes architectural interfaces for the former only. Specific implementations for various debugger host communication grammars can be created that make use of the facilities described in this specification.

The processor/platform abstraction is presented as a pair of protocol interfaces, which are the Debug Support protocol and the Debug Port protocol.

The Debug Support protocol abstracts the processor’s debugging facilities, namely a mechanism to manage the processor’s context via caller-installable exception handlers.

The Debug Port protocol abstracts the device that is used for communication between the host and target. Typically this will be a 16550 serial port, 1394 device, or other device that is nominally a serial stream.

Furthermore, a table driven, quiescent, memory-only mechanism for determining the base address of PE32+ images is provided to enable the debugger host to determine where images are located in memory.

Aside from timing differences that occur because of running code associated with the debug agent and user initiated changes to the machine context, the operation of the on-target debugger component must be transparent to the rest of the system. In addition, no portion of the debug agent that runs in interrupt context may make any calls to EFI services or other protocol interfaces.

The services described in this document do not comprise a complete debugger, rather they provide a minimal abstraction required to implement a wide variety of debugger solutions.

17.2 EFI Debug Support Protocol

This section defines the EFI Debug Support protocol which is used by the debug agent.

17.2.1 EFI Debug Support Protocol Overview

The debug-agent needs to be able to gain control of the machine when certain types of events occur; i.e., breakpoints, processor exceptions, etc. Additionally, the debug agent must also be able to periodically gain control during operation of the machine to check for asynchronous commands from the host. The EFI Debug Support protocol services enable these capabilities.

The EFI Debug Support protocol interfaces produce callback registration mechanisms which are used by the debug agent to register functions that are invoked either periodically or when specific processor exceptions. When they are invoked by the Debug Support driver, these callback functions are passed the current machine context record. The debug agent may modify this context record to change the machine context which is restored to the machine after the callback function returns. The debug agent does not run in the same context as the rest of UEFI and all modifications to the machine context are deferred until after the callback function returns.

It is expected that there will typically be two instances of the EFI Debug Support protocol in the system. One associated with the native processor instruction set (IA-32, x64, ARM, or Itanium processor family), and one for the EFI virtual machine that implements EFI byte code (EBC).

While multiple instances of the EFI Debug Support protocol are expected, there must never be more than one for any given instruction set.

EFI_DEBUG_SUPPORT_PROTOCOL

Summary

This protocol provides the services to allow the debug agent to register callback functions that are called either periodically or when specific processor exceptions occur.

GUID

```
#define EFI_DEBUG_SUPPORT_PROTOCOL_GUID \
    { 0x2755590C, 0x6F3C, 0x42FA, \
      0x9E, 0xA4, 0xA3, 0xBA, 0x54, 0x3C, 0xDA, 0x25 }
```

Protocol Interface Structure

```
typedef struct {
    EFI_INSTRUCTION_SET_ARCHITECTURE    Isa;
    EFI_GET_MAXIMUM_PROCESSOR_INDEX     GetMaximumProcessorIndex;
    EFI_REGISTER_PERIODIC_CALLBACK      RegisterPeriodicCallback;
    EFI_REGISTER_EXCEPTION_CALLBACK     RegisterExceptionCallback;
    EFI_INVALIDATE_INSTRUCTION_CACHE    InvalidateInstructionCache;
} EFI_DEBUG_SUPPORT_PROTOCOL;
```

Parameters

- Isa* Declares the processor architecture for this instance of the EFI Debug Support protocol.
- GetMaximumProcessorIndex* Returns the maximum processor index value that may be used with [EFI_DEBUG_SUPPORT_PROTOCOL.RegisterPeriodicCallback\(\)](#) and [EFI_DEBUG_SUPPORT_PROTOCOL.RegisterExceptionCallback\(\)](#). See the [EFI_DEBUG_SUPPORT_PROTOCOL.GetMaximumProcessorIndex\(\)](#) function description.
- RegisterPeriodicCallback* Registers a callback function that will be invoked periodically and asynchronously to the execution of EFI. See the [RegisterPeriodicCallback\(\)](#) function description.
- RegisterExceptionCallback* Registers a callback function that will be called each time the specified processor exception occurs. See the [RegisterExceptionCallback\(\)](#) function description.
- InvalidateInstructionCache* Invalidate the instruction cache of the processor. This is required by processor architectures where instruction and data caches are not coherent when instructions in the code under debug has been modified by the debug agent. See the [EFI_DEBUG_SUPPORT_PROTOCOL.InvalidateInstructionCache\(\)](#) function description.

Related Definitions

Refer to the Microsoft PE/COFF Specification revision 6.2 or later for **IMAGE_FILE_MACHINE** definitions.

Note: *At the time of publication of this specification, the latest revision of the PE/COFF specification was 6.2. The definition of `IMAGE_FILE_MACHINE_EBC` is not included in revision 6.2 of the PE/COFF specification. It will be added in a future revision of the PE/COFF specification.*

```
//
// Machine type definition
//
typedef enum {
    IsaIa32 = IMAGE_FILE_MACHINE_I386,           // 0x014C
    IsaX64  = IMAGE_FILE_MACHINE_X64,           // 0x8664
    IsaIpf  = IMAGE_FILE_MACHINE_IA64,          // 0x0200
    IsaEbc  = IMAGE_FILE_MACHINE_EBC,           // 0x0EBC
    IsaArm  = IMAGE_FILE_MACHINE_ARMTHUMB_MIXED // 0x1C2
    IsaAArch64 = IMAGE_FILE_MACHINE_AARCH64     // 0xAA64
} EFI_INSTRUCTION_SET_ARCHITECTURE;
```

Description

The EFI Debug Support protocol provides the interfaces required to register debug agent callback functions and to manage the processor's instruction stream as required. Registered callback functions are invoked in interrupt context when the specified event occurs.

The driver that produces the EFI Debug Support protocol is also responsible for saving the machine context prior to invoking a registered callback function and restoring it after the callback function returns prior to returning to the code under debug. If the debug agent has modified the context record, the modified context must be used in the restore operation.

Furthermore, if the debug agent modifies any of the code under debug (to set a software breakpoint for example), it must call the `InvalidateInstructionCache()` function for the region of memory that has been modified.

EFI_DEBUG_SUPPORT_PROTOCOL.GetMaximumProcessorIndex()

Summary

Returns the maximum value that may be used for the *ProcessorIndex* parameter in [EFI_DEBUG_SUPPORT_PROTOCOL.RegisterPeriodicCallback\(\)](#) and [EFI_DEBUG_SUPPORT_PROTOCOL.RegisterExceptionCallback\(\)](#).

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_GET_MAXIMUM_PROCESSOR_INDEX) (
    IN EFI_DEBUG_SUPPORT_PROTOCOL  *This,
    OUT UINTN                       *MaxProcessorIndex
);
```

Parameters

<i>This</i>	A pointer to the EFI_DEBUG_SUPPORT_PROTOCOL instance. Type EFI_DEBUG_SUPPORT_PROTOCOL is defined in this section.
<i>MaxProcessorIndex</i>	Pointer to a caller-allocated UINTN in which the maximum supported processor index is returned.

Description

The **GetMaximumProcessorIndex()** function returns the maximum processor index in the output parameter *MaxProcessorIndex*. This value is the largest value that may be used in the *ProcessorIndex* parameter for both **RegisterPeriodicCallback()** and **RegisterExceptionCallback()**. All values between 0 and *MaxProcessorIndex* must be supported by **RegisterPeriodicCallback()** and **RegisterExceptionCallback()**.

It is the responsibility of the caller to insure all parameters are correct. There is no provision for parameter checking by **GetMaximumProcessorIndex()**. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
-------------	--------------------------------------

EFI_DEBUG_SUPPORT_PROTOCOL.RegisterPeriodicCallback()**Summary**

Registers a function to be called back periodically in interrupt context.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_REGISTER_PERIODIC_CALLBACK) (
    IN EFI_DEBUG_SUPPORT_PROTOCOL  *This,
    IN UINTN                       ProcessorIndex,
    IN EFI_PERIODIC_CALLBACK       PeriodicCallback
);
```

Parameters

<i>This</i>	A pointer to the EFI_DEBUG_SUPPORT_PROTOCOL instance. Type EFI_DEBUG_SUPPORT_PROTOCOL is defined in Section 17.2 .
<i>ProcessorIndex</i>	Specifies which processor the callback function applies to.
<i>PeriodicCallback</i>	A pointer to a function of type PERIODIC_CALLBACK that is the main periodic entry point of the debug agent. It receives as a parameter a pointer to the full context of the interrupted execution thread.

Related Definitions

```
typedef
VOID (*EFI_PERIODIC_CALLBACK) (
    IN OUT EFI_SYSTEM_CONTEXT    SystemContext
);

// Universal EFI_SYSTEM_CONTEXT definition

typedef union {
    EFI_SYSTEM_CONTEXT_EBC        *SystemContextEbc;
    EFI_SYSTEM_CONTEXT_IA32      *SystemContextIa32;

```

Description

The **RegisterPeriodicCallback()** function registers and enables the on-target debug agent’s periodic entry point. To unregister and disable calling the debug agent’s periodic entry point, call **RegisterPeriodicCallback()** passing a **NULL** *PeriodicCallback* parameter.

The implementation must handle saving and restoring the processor context to/from the system context record around calls to the registered callback function.

If the interrupt is also used by the firmware for the EFI time base or some other use, two rules must be observed. First, the registered callback function must be called before any EFI processing takes place. Second, the Debug Support implementation must perform the necessary steps to pass control to the firmware’s corresponding interrupt handler in a transparent manner.

There is no quality of service requirement or specification regarding the frequency of calls to the registered *PeriodicCallback* function. This allows the implementation to mitigate a potential adverse impact to EFI timer based services due to the latency induced by the context save/restore and the associated callback function.

It is the responsibility of the caller to insure all parameters are correct. There is no provision for parameter checking by **RegisterPeriodicCallback()**. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_ALREADY_STARTED	Non- NULL <i>PeriodicCallback</i> parameter when a callback function was previously registered.
EFI_OUT_OF_RESOURCES	System has insufficient memory resources to register new callback function.

EFI_DEBUG_SUPPORT_PROTOCOL.RegisterExceptionCallback()**Summary**

Registers a function to be called when a given processor exception occurs.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *REGISTER_EXCEPTION_CALLBACK) (
    IN EFI_DEBUG_SUPPORT_PROTOCOL *This,
    IN UINTN ProcessorIndex,
    IN EFI_EXCEPTION_CALLBACK ExceptionCallback,
    IN EFI_EXCEPTION_TYPE ExceptionType
);
```

Parameters

<i>This</i>	A pointer to the EFI_DEBUG_SUPPORT_PROTOCOL instance. Type EFI_DEBUG_SUPPORT_PROTOCOL is defined in Section 17.2 .
<i>ProcessorIndex</i>	Specifies which processor the callback function applies to.
<i>ExceptionCallback</i>	A pointer to a function of type EXCEPTION_CALLBACK that is called when the processor exception specified by <i>ExceptionType</i> occurs. Passing NULL unregisters any previously registered function associated with <i>ExceptionType</i> .
<i>ExceptionType</i>	Specifies which processor exception to hook.

```

Description

The `RegisterExceptionCallback()` function registers and enables an exception callback function for the specified exception. The specified exception must be valid for the instruction set architecture. To unregister the callback function and stop servicing the exception, call `RegisterExceptionCallback()` passing a `NULL` *ExceptionCallback* parameter.

The implementation must handle saving and restoring the processor context to/from the system context record around calls to the registered callback function. No chaining of exception handlers is allowed.

It is the responsibility of the caller to insure all parameters are correct. There is no provision for parameter checking by **RegisterExceptionCallback()**. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_ALREADY_STARTED	Non- NULL <i>ExceptionCallback</i> parameter when a callback function was previously registered.
EFI_OUT_OF_RESOURCES	System has insufficient memory resources to register new callback function.

EFI_DEBUG_SUPPORT_PROTOCOL.InvalidateInstructionCache()

Summary

Invalidates processor instruction cache for a memory range. Subsequent execution in this range causes a fresh memory fetch to retrieve code to be executed.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INVALIDATE_INSTRUCTION_CACHE) (
    IN EFI_DEBUG_SUPPORT_PROTOCOL  *This,
    IN UINTN                       ProcessorIndex,
    IN VOID                         *Start,
    IN UINT64                       Length
);
```

Parameters

<i>This</i>	A pointer to the EFI_DEBUG_SUPPORT_PROTOCOL instance. Type EFI_DEBUG_SUPPORT_PROTOCOL is defined in Section 17.2 .
<i>ProcessorIndex</i>	Specifies which processor's instruction cache is to be invalidated.
<i>Start</i>	Specifies the physical base of the memory range to be invalidated.
<i>Length</i>	Specifies the minimum number of bytes in the processor's instruction cache to invalidate.

Description

Typical operation of a debugger may require modifying the code image that is under debug. This can occur for many reasons, but is typically done to insert/remove software break instructions. Some processor architectures do not have coherent instruction and data caches so modifications to the code image require that the instruction cache be explicitly invalidated in that memory region.

The **InvalidateInstructionCache()** function abstracts this operation from the debug agent and provides a general purpose capability to invalidate the processor's instruction cache.

It is the responsibility of the caller to insure all parameters are correct. There is no provision for parameter checking by

[EFI_DEBUG_SUPPORT_PROTOCOL.RegisterExceptionCallback\(\)](#). The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
-------------	--------------------------------------

17.3 EFI Debugport Protocol

This section defines the EFI Debugport protocol. This protocol is used by debug agent to communicate with the remote debug host.

17.3.1 EFI Debugport Overview

Historically, remote debugging has typically been done using a standard UART serial port to connect the host and target. This is obviously not possible in a legacy reduced system that does not have a UART. The Debugport protocol solves this problem by providing an abstraction that can support many different types of debugport hardware. The debug agent should use this abstraction to communicate with the host.

The interface is minimal with only reset, read, write, and poll abstractions. Since these functions are called in interrupt context, none of them may call any EFI services or other protocol interfaces.

Debugport selection and configuration is handled by setting defaults via an environment variable which contains a full device path to the debug port. This environment variable is used during the debugport driver's initialization to configure the debugport correctly. The variable contains a full device path to the debugport, with the last node (prior to the terminal node) being a debugport messaging node. See [Section 17.3.2](#) for details.

The driver must also produce an instance of the EFI Device Path protocol to indicate what hardware is being used for the debugport. This may be used by the OS to maintain the debugport across a call to [EFI_BOOT_SERVICES.ExitBootServices\(\)](#).

EFI_DEBUGPORT_PROTOCOL

Summary

This protocol provides the communication link between the debug agent and the remote host.

GUID

```
#define EFI_DEBUGPORT_PROTOCOL_GUID \
    {0xEBA4E8D2, 0x3858, 0x41EC, \
     {0xA2, 0x81, 0x26, 0x47, 0xBA, 0x96, 0x60, 0xD0}}
```

Protocol Interface Structure

```
typedef struct {
    EFI_DEBUGPORT_RESET           Reset;
    EFI_DEBUGPORT_WRITE          Write;
    EFI_DEBUGPORT_READ           Read;
    EFI_DEBUGPORT_POLL           Poll;
} EFI_DEBUGPORT_PROTOCOL;
```

Parameters

<i>Reset</i>	Resets the debugport hardware.
<i>Write</i>	Send a buffer of characters to the debugport device.
<i>Read</i>	Receive a buffer of characters from the debugport device.
<i>Poll</i>	Determine if there is any data available to be read from the debugport device.

Description

The Debugport protocol is used for byte stream communication with a debugport device. The debugport can be a standard UART Serial port, a USB-based character device, or potentially any character-based I/O device.

The attributes for all UART-style debugport device interfaces are defined in the DEBUGPORT variable (see [Section 17.3.2](#)).

EFI_DEBUGPORT_PROTOCOL.Reset()

Summary

Resets the debugport.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DEBUGPORT_RESET) (
    IN EFI_DEBUGPORT_PROTOCOL      *This
);
```

Parameters

This A pointer to the [EFI_DEBUGPORT_PROTOCOL](#) instance. Type [EFI_DEBUGPORT_PROTOCOL](#) is defined in [Section 17.3](#).

Description

The **Reset()** function resets the debugport device.

It is the responsibility of the caller to insure all parameters are valid. There is no provision for parameter checking by **Reset()**. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The debugport device was reset and is in usable state.
EFI_DEVICE_ERROR	The debugport device could not be reset and is unusable.

EFI_DEBUGPORT_PROTOCOL.Write()

Summary

Writes data to the debugport.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DEBUGPORT_WRITE) (
    IN EFI_DEBUGPORT_PROTOCOL      *This,
    IN UINT32                       Timeout,
    IN OUT UINTN                    *BufferSize,
    IN VOID                          *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_DEBUGPORT_PROTOCOL instance. Type EFI_DEBUGPORT_PROTOCOL is defined in Section 17.3 .
<i>Timeout</i>	The number of microseconds to wait before timing out a write operation.
<i>BufferSize</i>	On input, the requested number of bytes of data to write. On output, the number of bytes of data actually written.
<i>Buffer</i>	A pointer to a buffer containing the data to write.

Description

The **Write()** function writes the specified number of bytes to a debugport device. If a timeout error occurs while data is being sent to the debugport, transmission of this buffer will terminate, and **EFI_TIMEOUT** will be returned. In all cases the number of bytes actually written to the debugport device is returned in *BufferSize*.

It is the responsibility of the caller to insure all parameters are valid. There is no provision for parameter checking by **Write()**. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The data was written.
EFI_DEVICE_ERROR	The device reported an error.
EFI_TIMEOUT	The data write was stopped due to a timeout.

EFI_DEBUGPORT_PROTOCOL.Read()

Summary

Reads data from the debugport.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DEBUGPORT_READ) (
    IN EFI_DEBUGPORT_PROTOCOL      *This,
    IN UINT32                       Timeout,
    IN OUT UINTN                    *BufferSize,
    OUT VOID                        *Buffer
);
```

Parameters

<i>This</i>	A pointer to the EFI_DEBUGPORT_PROTOCOL instance. Type EFI_DEBUGPORT_PROTOCOL is defined in Section 17.3 .
<i>Timeout</i>	The number of microseconds to wait before timing out a read operation.
<i>BufferSize</i>	A pointer to an integer which, on input contains the requested number of bytes of data to read, and on output contains the actual number of bytes of data read and returned in <i>Buffer</i> .
<i>Buffer</i>	A pointer to a buffer into which the data read will be saved.

Description

The **Read()** function reads a specified number of bytes from a debugport. If a timeout error or an overrun error is detected while data is being read from the debugport, then no more characters will be read, and **EFI_TIMEOUT** will be returned. In all cases the number of bytes actually read is returned in **BufferSize*.

It is the responsibility of the caller to insure all parameters are valid. There is no provision for parameter checking by **Read()**. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The data was read.
EFI_DEVICE_ERROR	The debugport device reported an error.
EFI_TIMEOUT	The operation was stopped due to a timeout or overrun.

EFI_DEBUGPORT_PROTOCOL.Poll()

Summary

Checks to see if any data is available to be read from the debugport device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DEBUGPORT_POLL) (
    IN EFI_DEBUGPORT_PROTOCOL          *This
);
```

Parameters

This A pointer to the [EFI_DEBUGPORT_PROTOCOL](#) instance. Type [EFI_DEBUGPORT_PROTOCOL](#) is defined in [Section 17.3](#).

Description

The `Poll()` function checks if there is any data available to be read from the debugport device and returns the result. No data is actually removed from the input stream. This function enables simpler debugger design since buffering of reads is not necessary by the caller.

Status Codes Returned

EFI_SUCCESS	At least one byte of data is available to be read.
EFI_NOT_READY	No data is available to be read.
EFI_DEVICE_ERROR	The debugport device is not functioning correctly.

17.3.2 Debugport Device Path

The debugport driver must establish and maintain an instance of the EFI Device Path protocol for the debugport. A graceful handoff of debugport ownership between the EFI Debugport driver and an OS debugport driver requires that the OS debugport driver can determine the type, location, and configuration of the debugport device.

The Debugport Device Path is a vendor-defined messaging device path with no data, only a GUID. It is used at the end of a conventional device path to tag the device for use as the debugport. For example, a typical UART debugport would have the following fully qualified device path:

```
PciRoot(0)/Pci(0x1f,0)/ACPI(PNP0501,0)/UART(115200,N,8,1)/
DebugPort()
```

The Vendor_GUID that defines the debugport device path is the same as the debugport protocol GUID, as defined below.

```
#define DEVICE_PATH_MESSAGING_DEBUGPORT \
    EFI_DEBUGPORT_PROTOCOL_GUID
```

[Table 140](#) shows all fields of the debugport device path.

Table 140. Debugport Messaging Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path.
Sub Type	1	1	Sub Type 10 – Vendor.
Length	2	2	Length of this structure in bytes. Length is 20 bytes.
Vendor_GUID	4	16	DEVICE_PATH_MESSAGING_DEBUGPORT.

17.3.3 EFI Debugport Variable

Even though there may be more than one hardware device that could function as a debugport in a system, only one debugport may be active at a time. The DEBUGPORT variable is used to declare which hardware device will act as the debugport, and what communication parameters it should assume.

Like all EFI variables, the DEBUGPORT variable has both a name and a GUID. The name is “DEBUGPORT.” The GUID is the same as the **EFI_DEBUGPORT_PROTOCOL_GUID**:

```
#define EFI_DEBUGPORT_VARIABLE_NAME L"DEBUGPORT"
#define EFI_DEBUGPORT_VARIABLE_GUID EFI_DEBUGPORT_PROTOCOL_GUID
```

The data contained by the DEBUGPORT variable is a fully qualified debugport device path (see [Section 17.3.2](#)).

The desired communication parameters for the debugport are declared in the DEBUGPORT variable. The debugport driver must read this variable during initialization to determine how to configure the debug port.

To reduce the required complexity of the debugport driver, the debugport driver is not required to support all possible combinations of communication parameters. What combinations of parameters are possible is implementation specific.

Additionally debugport drivers implemented for PNP0501 devices, that is debugport devices with a PNP0501 ACPI node in the device path, must support the following defaults. These defaults must be used in the absence of a DEBUGPORT variable, or when the communication parameters specified in the DEBUGPORT variable are not supported by the driver.

- Baud : 115200
- 8 data bits
- No parity
- 1 stop bit
- No flow control (See Appendix A for flow control details)

In the absence of the DEBUGPORT variable, the selection of which port to use as the debug port is implementation specific.

Future revisions of this specification may define new defaults for other debugport types.

The debugport device path must be constructed to reflect the actual settings for the debugport. Any code needing to know the state of the debug port must reference the device path rather than the

DEBUGPORT variable, since the debugport may have assumed a default setting in spite of the existence of the DEBUGPORT variable.

If it is not possible to configure the debug port using either the settings declared in the DEBUGPORT variable or the default settings for the particular debugport type, the driver initialization must not install any protocol interfaces and must exit with an error.

17.4 EFI Debug Support Table

This chapter defines the EFI Debug Support Table which is used by the debug agent or an external debugger to determine loaded image information in a quiescent manner.

17.4.1 Overview

Every executable image loaded in EFI is represented by an EFI handle populated with an instance of the [EFI LOADED IMAGE PROTOCOL](#). This handle is known as an “image handle.” The associated Loaded Image protocol provides image information that is of interest to a source level debugger. Normal EFI executables can access this information by using EFI services to locate all instances of the Loaded Image protocol.

A debugger has two problems with this scenario. First, if it is an external hardware debugger, the location of the EFI system table is not known. Second, even if the location of the EFI system table is known, the services contained therein are generally unavailable to a debugger either because it is an on-target debugger that is running in interrupt context, or in the case of an external hardware debugger there is no debugger code running on the target at all.

Since a source level debugger must be capable of determining image information for all loaded images, an alternate mechanism that does not use EFI services must be provided. Two features are added to the EFI system software to enable this capability.

First, an alternate mechanism of locating the EFI system table is required. A check-summed structure containing the physical address of the EFI system table is created and located on a 4M aligned memory address. A hardware debugger can search memory for this structure to determine the location of the EFI system table.

Second, an [EFI_CONFIGURATION_TABLE](#) is published that leads to a database of pointers to all instances of the Loaded Image protocol. Several layers of indirection are used to allow dynamically managing the data as images are loaded and unloaded. Once the address of the EFI system table is known, it is possible to discover a complete and accurate list of EFI images. (Note that the EFI core itself must be represented by an instance of the Loaded Image protocol.)

[Figure 55](#) illustrates the table indirection and pointer usage.

Figure 55. Debug Support Table Indirection and Pointer Usage

17.4.2 EFI System Table Location

The EFI system table can be located by an off-target hardware debugger by searching for the **EFI_SYSTEM_TABLE_POINTER** structure. The **EFI_SYSTEM_TABLE_POINTER** structure is located on a 4M boundary as close to the top of physical memory as feasible. It may be found searching for the **EFI_SYSTEM_TABLE_SIGNATURE** on each 4M boundary starting at the top of memory and scanning down. When the signature is found, the entire structure must be verified using the *Crc32* field. The 32-bit CRC of the entire structure is calculated assuming the *Crc32* field is zero. This value is then written to the *Crc32* field.

```

typedef struct _EFI_SYSTEM_TABLE_POINTER {
    UINT64          Signature;
    EFI_PHYSICAL_ADDRESS EfiSystemTableBase;
    UINT32          Crc32;
} EFI_SYSTEM_TABLE_POINTER;
  
```

- Signature* A constant **UINT64** that has the value **EFI_SYSTEM_TABLE_SIGNATURE** (see the EFI 1.0 specification).
- EfiSystemTableBase* The physical address of the EFI system table.
- Crc32* A 32-bit CRC value that is used to verify the **EFI_SYSTEM_TABLE_POINTER** structure is valid.

17.4.3 EFI Image Info

The **EFI_DEBUG_IMAGE_INFO_TABLE** is an array of pointers to **EFI_DEBUG_IMAGE_INFO** unions. Each member of an **EFI_DEBUG_IMAGE_INFO** union is a pointer to a data structure representing a particular image type. For each image that has been loaded, there is an appropriate

image data structure with a pointer to it stored in the **EFI_DEBUG_IMAGE_INFO_TABLE**. Data structures for normal images and SMM images are defined. All other image types are reserved for future use.

The process of locating the **EFI_DEBUG_IMAGE_INFO_TABLE** begins with an EFI configuration table.

```
//
// EFI_DEBUG_IMAGE_INFO_TABLE configuration table
//     GUID declaration - {49152E77-1ADA-4764-B7A2-7AFEFED95E8B}
//
#define EFI_DEBUG_IMAGE_INFO_TABLE_GUID \
    {0x49152E77,0x1ADA,0x4764,\
     {0xB7,0xA2,0x7A,0xFE,0xFE,0xD9,0x5E,0x8B } }
```

The configuration table leads to an **EFI_DEBUG_IMAGE_INFO_TABLE_HEADER** structure that contains a pointer to the **EFI_DEBUG_IMAGE_INFO_TABLE** and some status bits that are used to control access to the **EFI_DEBUG_IMAGE_INFO_TABLE** when it is being updated.

```
//
// UpdateStatus bits
//
#define EFI_DEBUG_IMAGE_INFO_UPDATE_IN_PROGRESS  0x01
#define EFI_DEBUG_IMAGE_INFO_TABLE_MODIFIED      0x02

typedef struct {
    volatile UINT32      UpdateStatus;
    UINT32               TableSize;
    EFI_DEBUG_IMAGE_INFO *EfiDebugImageInfoTable;
} EFI_DEBUG_IMAGE_INFO_TABLE_HEADER;
```

UpdateStatus *UpdateStatus* is used by the system to indicate the state of the debug image info table.

The **EFI_DEBUG_IMAGE_INFO_UPDATE_IN_PROGRESS** bit must be set when the table is being modified. Software consuming the table must qualify the access to the table with this bit.

The **EFI_DEBUG_IMAGE_INFO_TABLE_MODIFIED** bit is always set by software that modifies the table. It may be cleared by software that consumes the table once the entire table has been read. It is essentially a sticky version of the **EFI_DEBUG_IMAGE_INFO_UPDATE_IN_PROGRESS** bit and is intended to provide an efficient mechanism to minimize the number of times the table must be scanned by the consumer.

TableSize The number of **EFI_DEBUG_IMAGE_INFO** elements in the array pointed to by *EfiDebugImageInfoTable*.

EfiDebugImageInfoTable A pointer to the first element of an array of **EFI_DEBUG_IMAGE_INFO** structures.

```
#define EFI_DEBUG_IMAGE_INFO_TYPE_NORMAL 0x01
```

```
typedef union {
    UINT32 *ImageInfoType;
    EFI_DEBUG_IMAGE_INFO_NORMAL *NormalImage;
} EFI_DEBUG_IMAGE_INFO;
```

```
typedef struct {
    UINT32 ImageInfoType;
    EFI_LOADED_IMAGE_PROTOCOL *LoadedImageProtocolInstance;
    EFI_HANDLE ImageHandle;
} EFI_DEBUG_IMAGE_INFO_NORMAL;
```

ImageInfoType Indicates the type of image info structure. For PE32 EFI images, this is set to **EFI_DEBUG_IMAGE_INFO_TYPE_NORMAL**.

LoadedImageProtocolInstance A pointer to an instance of the loaded image protocol for the associated image.

ImageHandle Indicates the image handle of the associated image.

Protocols — Compression Algorithm Specification

In EFI firmware storage, binary codes/data are often compressed to save storage space. These compressed codes/data are extracted into memory for execution at boot time. This demands an efficient lossless compression/decompression algorithm. The compressor must produce small compressed images, and the decompressor must operate fast enough to avoid delays at boot time.

This chapter describes in detail the UEFI compression/decompression algorithm, as well as the EFI Decompress Protocol. The EFI Decompress Protocol provides a standard decompression interface for use at boot time.

18.1 Algorithm Overview

In this chapter the term “**character**” denotes a single byte and the term “**string**” denotes a series of concatenated characters.

The compression/decompression algorithm used in EFI firmware storage is a combination of the LZ77 algorithm and Huffman Coding. The LZ77 algorithm replaces a repeated string with a pointer to the previous occurrence of the string. Huffman Coding encodes symbols in a way that the more frequently a symbol appears in a text, the shorter the code that is assigned to it.

The compression process contains two steps:

- The first step is to find repeated strings (using LZ77 algorithm) and produce intermediate data. Beginning with the first character, the compressor scans the source data and determines if the characters starting at the current position can form a string previously appearing in the text. If a long enough matching string is found, the compressor will output a pointer to the string. If the pointer occupies more space than the string itself, the compressor will output the original character at the current position in the source data. Then the compressor advances to the next position and repeats the process. To speed up the compression process, the compressor dynamically maintains a **String Info Log** to record the positions and lengths of strings encountered, so that string comparisons are performed quickly by looking up the String Info Log.

Because a compressor cannot have unlimited resources, as the compression continues the compressor removes “old” string information. This prevents the String Info Log from becoming too large. As a result, the algorithm can only look up repeated strings within the range of a fixed-sized “sliding window” behind the current position.

In this way, a stream of intermediate data is produced which contains two types of symbols: the **Original Characters** (to be preserved in the decompressed data), and the **Pointers** (representing a previous string). A Pointer consists of two elements: the **String Position** and the **String Length**, representing the location and the length of the target string, respectively.

- To improve the compression ratio further, Huffman Coding is utilized as the second step.

The intermediate data (consisting of original characters and pointers) is divided into **Blocks** so that the compressor can perform Huffman Coding on a Block immediately after it is generated; eliminating the need for a second pass from the beginning after the intermediate data has been generated. Also, since symbol frequency distribution may differ in different parts of the intermediate data, Huffman Coding can be optimized for each specific Block. The compressor determines Block Size for each Block according to the specifications defined in [Section 18.2](#).

In each Block, two symbol sets are defined for Huffman Coding. The **Char&Len Set** consists of the Original Characters plus the String Lengths and the **Position Set** consists of String Positions (Note that the two elements of a Pointer belong to separate symbol sets). The Huffman Coding schemes applied on these two symbol sets are independent.

The algorithm uses “canonical” Huffman Coding so a Huffman tree can be represented as an array of code lengths in the order of the symbols in the symbol set. This code length array represents the Huffman Coding scheme for the symbol set. Both the Char&Len Set code length array and the Position Set code length array appear in the Block Header.

Huffman coding is used on the code length array of the Char&Len Set to define a third symbol set. The **Extra Set** is defined based on the code length values in the Char&Len Set code length array. The code length array for the Huffman Coding of Extra Set also appears in the Block Header together with the other two code length arrays. For exact format of the Block Header, see [Section 18.2.3.1](#).

The decompression process is straightforward given that the compression process is known. The decompressor scans the compressed data and decodes the symbols one by one, according to the Huffman code mapping tables generated from code length arrays. Along the process, if it encounters an original character, it outputs it; if it encounters a pointer, it looks it up in the already decompressed data and outputs the associated string.

18.2 Data Format

This section describes in detail the format of the compressed data produced by the compressor. The compressed data serves as input to the decompressor and can be fully extracted to the original source data.

18.2.1 Bit Order

In computer data representation, a byte is the minimum unit and there is no differentiation in the order of bits within a byte. However, the compressed data is a sequence of bits rather than a sequence of bytes and as a result the order of bits in a byte needs to be defined. In a compressed data stream, the higher bits are defined to precede the lower bits in a byte. [Figure 56](#) illustrates a compressed data sequence written as bytes from left to right. For each byte, the bits are written in an order with bit 7 (the highest bit) at the left and bit 0 (the lowest bit) at the right. Concatenating the bytes from left to right forms a bit sequence.

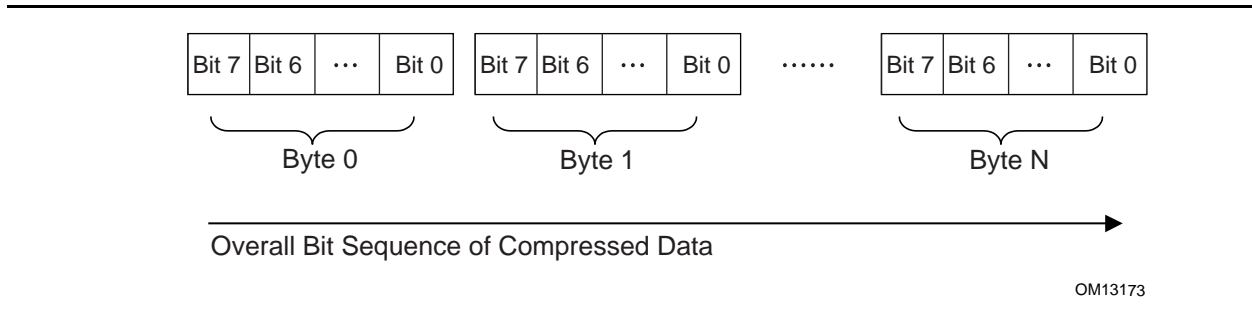

Figure 56. Bit Sequence of Compressed Data

The bits of the compressed data are actually formed by a sequence of data units. These data units have variable bit lengths. The bits of each data unit are arranged so that the higher bit of the data unit precedes the lower bit of the data unit.

18.2.2 Overall Structure

The compressed data begins with two 32-bit numerical fields: the compressed size and the original size. The compressed data following these two fields is composed of one or more Blocks. Each Block is a unit for Huffman Coding with a coding scheme independent of the other Blocks. Each Block is composed of a Block Header containing the Huffman code trees for this Block and a Block Body with the data encoded using the coding scheme defined by the Huffman trees. The compressed data is terminated by an additional byte of zero.

The overall structure of the compressed data is shown in [Figure 57](#).

Figure 57. Compressed Data Structure

Note the following:

- Blocks are of variable lengths.
- Block lengths are counted by bits and not necessarily divisible by 8. Blocks are tightly packed (there are no padding bits between blocks). Neither the starting position nor ending position of a Block is necessarily at a byte boundary. However, if the last Block is not terminated at a byte boundary, there should be some bits of 0 to fill up the remaining bits of the last byte of the block, before the terminator byte of 0.
- Compressed Size =
Size in bytes of (Block 0 + Block 1 + ... + Block N + Filling Bits (if any) + Terminator).
- Original Size is the size in bytes of original data.

- Both Compressed Size and Original Size are “little endian” (starting from the least significant byte).

18.2.3 Block Structure

A Block is composed of a Block Header and a Block Body, as shown in [Figure 58](#). These two parts are packed tightly (there are no padding bits between them). The lengths in bits of Block Header and Block Body are not necessarily divisible by eight.

OM13175

Figure 58. Block Structure

18.2.3.1 Block Header

The Block Header contains the Huffman encoding information for this block. Since “canonical” Huffman Coding is being used, a Huffman tree is represented as an array of code lengths in increasing order of the symbols in the symbol set. Code lengths are limited to be less than or equal to 16 bits. This requires some extra handling of Huffman codes in the compressor, which is described in [Section 18.3](#).

There are three code length arrays for three different symbol sets in the Block Header: one for the Extra Set, one for the Char&Len Set, and one for the Position Set.

The Block Header is composed of the tightly packed (no padding bits) fields described in [Table 141](#).

Table 141. Block Header Fields

Field Name	Length (bits)	Description
Block Size	16	The size of this Block. Block Size is defined as the number of original characters plus the number of pointers that appear in the Block Body: Block Size = Number of Original Characters in the Block Body + Number of Pointers in the Block Body.
Extra Set Code Length Array Size	5	The number of code lengths in the Extra Set Code Length Array. The Extra Set Code Length Array contains code lengths of the Extra Set in increasing order of the symbols, and if all symbols greater than a certain symbol have zero code length, the Extra Set Code Length Array terminates at the last nonzero code length symbol. Since there are 19 symbols in the Extra Set (see the description of the Char&Len Set Code Length Array), the maximum Extra Set Code Length Array Size is 19.

Field Name	Length (bits)	Description
Extra Set Code Length Array	Variable	<p>If Extra Set Code Length Array Size is 0, then this field is a 5-bit value that represents the only Huffman code used.</p> <p>If Extra Set Code Length Array Size is not 0, then this field is an encoded form of a concatenation of code lengths in increasing order of the symbols.</p> <p>The concatenation of Code lengths are encoded as follows: If a code length is less than 7, then it is encoded as a 3-bit value; If a code length is equal to or greater than 7, then it is encoded as a series of “1”s followed by a terminating “0.” The number of “1”s = Code length – 4. For example, code length “ten” is encoded as “1111110”; code length “seven” is encoded as “1110.”</p> <p>After the third length of the code length concatenation, a 2-bit value is used to indicate the number of consecutive zero lengths immediately after the third length. (Note this 2-bit value only appears once after the third length, and does NOT appear multiple times after every 3rd length.) This 2-bit value ranges from 0 to 3. For example, if the 2-bit value is “00,” then it means there are no zero lengths at the point, and following encoding starts from the fourth code length; if the 2-bit value is “10” then it means the fourth and fifth length are zero and following encoding starts from the sixth code length.</p>
Position Set Code Length Array Size	4	<p>The number of code lengths in the Position Set Code Length Array. The Position Set Code Length Array contains code lengths of Position Set in increasing order of the symbols in the Position Set, and if all symbols greater than a certain symbol have zero code length, the Position Set Code Length Array terminates at the last nonzero code length symbol. Since there are 14 symbols in the Position Set (see 3.3.2), the maximum Position Set Code Length Array Size is 14.</p>

Field Name	Length (bits)	Description
Char&Len Set Code Length Array	Variable	<p>If Char&Len Set Code Length Array Size is 0, then this field is a 9-bit value that represents the only Huffman code used.</p> <p>If Char&Len Set Code Length Array Size is not 0, then this field is an encoded form of a concatenation of code lengths in increasing order of the symbols.</p> <p>The concatenation of Code lengths are two-step encoded:</p> <p>Step 1:</p> <p>If a code length is not zero, then it is encoded as “code length + 2”;</p> <p>If a code length is zero, then the number of consecutive zero lengths starting from this code length is counted -- If the count is equal to or less than 2, then the code “0” is used for each zero length; if the count is greater than 2 and less than 19, then the code “1” followed by a 4-bit value of “count – 3” is used for these consecutive zero lengths; if the count is equal to 19, then it is treated as “1 + 18,” and a code “0” and a code “1” followed by a 4-bit value of “15” are used for these consecutive zero lengths; if the count is greater than 19, then the code “2” followed by a 9-bit value of “count – 20” is used for these consecutive zero lengths.</p> <p>Step 2:</p> <p>The second step encoding is a Huffman encoding of the codes produced by first step. (While encoding codes “1” and “2,” their appended values are not encoded and preserved in the resulting text). The code lengths of generated Huffman tree are just the contents of the Extra Set Code Length Array.</p>
Position Set Code Length Array Size	4	<p>The number of code lengths in the Position Set Code Length Array. The Position Set Code Length Array contains code lengths of Position Set in increasing order of the symbols in the Position Set, and if all symbols greater than a certain symbol have zero code length, the Position Set Code Length Array terminates at the last nonzero code length symbol. Since there are 14 symbols in the Position Set (see 3.3.2), the maximum Position Set Code Length Array Size is 14.</p>
Position Set Code Length Array	Variable	<p>If Position Set Code Length Array Size is 0, then this field is a 5-bit value that represents the only Huffman code used.</p> <p>If Position Set Code Length Array Size is not 0, then this field is an encoded form of a concatenation of code lengths in increasing order of the symbols.</p> <p>The concatenation of Code lengths are encoded as follows:</p> <p>If a code length is less than 7, then it is encoded as a normal 3-bit value;</p> <p>If a code length is equal to or greater than 7, then it is encoded as a series of “1”s followed by a terminating “0.” The number of “1”s = Code length – 4. For example, code length “10” is encoded as “111110”; code length “7” is encoded as “1110.”</p>

18.2.3.2 Block Body

The Block Body is simply a mixture of Original Characters and Pointers, while each Pointer has two elements: String Length preceding String Position. All these data units are tightly packed together.

Figure 59. Block Body

The Original Characters, String Lengths and String Positions are all Huffman coded using the Huffman trees presented in the Block Header, with some additional variations. The exact format is described below:

An Original Character is a byte in the source data. A String Length is a value that is greater than 3 and less than 257 (this range should be ensured by the compressor). By calculating “(String Length – 3) | 0x100,” a value set is obtained that ranges from 256 to 509. By combining this value set with the value set of Original Characters (0 ~ 255), the Char&Len Set (ranging from 0 to 509) is generated for Huffman Coding.

A String Position is a value that indicates the distance between the current position and the target string. The String Position value is defined as “Current Position – Starting Position of the target string - 1.” The String Position value ranges from 0 to 8190 (so 8192 is the “sliding window” size, and this range should be ensured by the compressor). The lengths of the String Position values (in binary form) form a value set ranging from 0 to 13 (it is assumed that value 0 has length of 0). This value set is the Position Set for Huffman Coding. The full representation of a String Position value is composed of two consecutive parts: one is the Huffman code for the value length; the other is the actual String Position value of “length - 1” bits (excluding the highest bit since the highest bit is always “1”). For example, String Position value 18 is represented as: Huffman code for “5” followed by “0010.” If the value length is 0 or 1, then no value is appended to the Huffman code. This kind of representation favors small String Position values, which is a hint for compressor design.

18.3 Compressor Design

The compressor takes the source data as input and produces a compressed image. This section describes the design used in one possible implementation of a compressor that follows the UEFI Compression Algorithm. The source code that illustrates an implementation of this specific design is listed in Appendix H.

18.3.1 Overall Process

The compressor scans the source data from the beginning, character by character. As the scanning proceeds, the compressor generates Original Characters or Pointers and outputs the compressed data packed in a series of Blocks representing individual Huffman coding units.

The compressor maintains a String Info Log containing data that facilitates string comparison. Old data items are deleted and new data items are inserted regularly.

The compressor does not output a Pointer immediately after it sees a matching string for the current position. Instead, it delays its decision until it gets the matching string for the next position. The compressor has two criteria at hand: one is that the former match length should be no shorter than three characters; the other is that the former match length should be no shorter than the latter match length. Only when these two criteria are met does the compressor output a Pointer to the former matching string.

The overall process of compression can be described by following pseudo code:

```

Set the Current Position at the beginning of the source data;
Delete the outdated string info from the String Info Log;
Search the String Info Log for matching string;
Add the string info of the current position into the String Info Log;
WHILE not end of source data DO
    Remember the last match;
    Advance the Current Position by 1;
    Delete the outdated String Info from the String Info Log;
    Search the String Info Log for matching string;
    Add the string info of the Current Position into the String Info Log;
    IF the last match is shorter than 3 characters or this match is longer than
    the last match THEN
        Call Output()* to output the character at the previous position as an
        Original Character;
    ELSE
        Call Output()* to output a Pointer to the last matching string;
    WHILE (--last match length) > 0 DO
        Advance the Current Position by 1;
        Delete the outdated piece of string info from the String Info Log;
        Add the string info of the current position into the String Info Log;
    ENDWHILE
ENDIF
ENDWHILE

```

The *Output()* is the function that is responsible for generating Huffman codes and Blocks. It accepts an Original Character or a Pointer as input and maintains a Block Buffer to temporarily store data units that are to be Huffman coded. The following pseudo code describes the function:

```

FUNCTION NAME: Output
INPUT: an Original Character or a Pointer

Put the Original Character or the Pointer into the Block Buffer;
Advance the Block Buffer position pointer by 1;
IF the Block Buffer is full THEN
    Encode the Char&Len Set in the Block buffer;
    Encode the Position Set in the Block buffer;
    Encode the Extra Set;
    Output the Block Header containing the code length arrays;
    Output the Block Body containing the Huffman encoded Original Characters and
    Pointers;
    Reset the Block Buffer position pointer to point to the beginning of the
    Block buffer;
ENDIF

```

18.3.2 String Info Log

The provision of the String Info Log is to speed up the process of finding matching strings. The design of this has significant impact on the overall performance of the compressor. This section describes in detail how String Info Log is implemented and the typical operations on it.

18.3.2.1 Data Structures

The String Info Log is implemented as a set of search trees. These search trees are dynamically updated as the compression proceeds through the source data. The structure of a typical search tree is depicted in [Figure 60](#).

OM13177

Figure 60. String Info Log Search Tree

There are three types of nodes in a search tree: the root node, internal nodes, and leaves. The root node has a “character” attribute, which represents the starting character of a string. Each edge also has a “character” attribute, which represents the next character in the string. Each internal node has a “level” attribute, which indicates the character on any edge that leads to its child nodes is the “level + 1”th character in the string. Each internal node or leaf has a “position” attribute that indicates the string’s starting position in the source data.

To speed up the tree searching, a hash function is used. Given the parent node and the edge-character, the hash function will quickly find the expected child node.

18.3.2.2 Searching the Tree

Traversing the search tree is performed as follows:

The following example uses the search tree shown in [Figure 60](#) above. Assume that the current position in the source data contains the string “camxrsxpj...”

1. The starting character “c” is used to find the root of the tree. The next character “a” is used to follow the edge from node 1 to node 2. The “position” of node 2 is 500, so a string starting with

“ca” can be found at position 500. The string at the current position is compared with the string starting at position 500.

2. Node 2 is at Level 3; so at most three characters are compared. Assume that the three-character comparison passes.
3. The fourth character “x” is used to follow the edge from Node 2 to Node 5. The position value of node 5 is 400, which means there is a string located in position 400 that starts with “cam” and the character at position 403 is an “x.”
4. Node 5 is at Level 8, so the fifth to eighth characters of the source data are compared with the string starting at position 404. Assume the strings match.
5. At this point, the ninth character “p” has been reached. It is used to follow the edge from Node 5 to Node 7.
6. This process continues until a mismatch occurs, or the length of the matching strings exceeds the predefined `MAX_MATCH_LENGTH`. The most recent matching string (which is also the longest) is the desired matching string.

18.3.2.3 Adding String Info

String info needs to be added to the String Info Log for each position in the source data. Each time a search for a matching string is performed, the new string info is inserted for the current position. There are several cases that can be discussed:

1. No root is found for the first character. A new tree is created with the root node labeled with the starting character and a child leaf node with its edge to the root node labeled with the second character in the string. The “position” value of the child node is set to the current position.
2. One root node matches the first character, but the second character does not match any edge extending from the root node. A new child leaf node is created with its edge labeled with the second character. The “position” value of the new leaf child node is set to the current position.
3. A string comparison succeeds with an internal node, but a matching edge for the next character does not exist. This is similar to (2) above. A new child leaf node is created with its edge labeled with the character that does not exist. The “position” value of the new leaf child node is set to the current position.
4. A string comparison exceeds `MAX_MATCH_LENGTH`. Note: This only happens with leaf nodes. For this case, the “position” value in the leaf node is updated with the current position.
5. If a string comparison with an internal node or leaf node fails (mismatch occurs before the “Level + 1”th character is reached or `MAX_MATCH_LENGTH` is exceeded), then a “split” operation is performed as follows:

Suppose a comparison is being performed with a level 9 Node, at position 350, and the current position is 1005. If the sixth character at position 350 is an “x” and the sixth character at position 1005 is a “y,” then a mismatch will occur. In this case, a new internal node and a new child node are inserted into the tree, as depicted in [Figure 61](#).

OM13178

Figure 61. Node Split

The b) portion of [Figure 61](#) has two new inserted nodes, which reflects the new string information that was found at the current position. The process splits the old node into two child nodes, and that is why this operation is called a “split.”

18.3.2.4 Deleting String Info

The String Info Log will grow as more and more string information is logged. The size of the String Info Log must be limited, so outdated information must be removed on a regular basis. A sliding window is maintained behind the current position, and the searches are always limited within the range of the sliding window. Each time the current position is advanced, outdated string information that falls outside the sliding window should be removed from the tree. The search for outdated string information is simplified by always updating the nodes’ “position” attribute when searching for matching strings.

18.3.3 Huffman Code Generation

Another major component of the compressor design is generation of the Huffman Code.

Huffman Coding is applied to the Char&Len Set, the Position Set, and the Extra Set. The Huffman Coding used here has the following features:

- The Huffman tree is represented as an array of code lengths (“canonical” Huffman Coding);

- The maximum code length is limited to 16 bits.

The Huffman code generation process can be divided into three steps. These are the generation of Huffman tree, the adjustment of code lengths, and the code generation.

18.3.3.1 Huffman Tree Generation

This process generates a typical Huffman tree. First, the frequency of each symbol is counted, and a list of nodes is generated with each node containing a symbol and the symbol's frequency. The two nodes with the lowest frequency values are merged into a single node. This new node becomes the parent node of the two nodes that are merged. The frequency value of this new parent node is the sum of the two child nodes' frequency values. The node list is updated to include the new parent node but exclude the two child nodes that are merged. This process is repeated until there is a single node remaining that is the root of the generated tree.

18.3.3.2 Code Length Adjustment

The leaf nodes of the tree generated by the previous step represent all the symbols that were generated. Traditionally the code for each symbol is found by traversing the tree from the root node to the leaf node. Going down a left edge generates a "0," and going down a right edge generates a "1." However, a different approach is used here. The number of codes of each code length is counted. This generates a 16-element *LengthCount* array, with *LengthCount[i]* = Number Of Codes whose Code Length is *i*. Since a code length may be longer than 16 bits, the sixteenth entry of the *LengthCount* array is set to the Number Of Codes whose Code Length is greater than or equal to 16.

The *LengthCount* array goes through further adjustment described by following code:

```

INT32 i, k;
UINT32 cum;

cum = 0;
for (i = 16; i > 0; i--) {
    cum += LengthCount[i] << (16 - i);
}
while (cum != (1U << 16)) {
    LengthCount[16]--;
    for (i = 15; i > 0; i--) {
        if (LengthCount[i] != 0) {
            LengthCount[i]--;
            LengthCount[i+1] += 2;
            break;
        }
    }
    cum--;
}

```

18.3.3.3 Code Generation

In the previous step, the count of each length was obtained. Now, each symbol is going to be assigned a code. First, the length of the code for each symbol is determined. Naturally, the code lengths are assigned in such a way that shorter codes are assigned to more frequently appearing

symbols. A *CodeLength* array is generated with $CodeLength[i] =$ the code length of symbol i . Given this array, a code is assigned to each symbol using the algorithm described by the pseudo code below (the resulting codes are stored in array *Code* such that $Code[i] =$ the code assigned to symbol i):

```

INT32    i;
UINT16   Start[18];

Start[1] = 0;

for (i = 1; i <= 16; i++) {
    Start[i + 1] = (UINT16) ((Start[i] + LengthCount[i]) << 1);
}

for (i = 0; i < NumberOfSymbols; i++) {
    Code[i] = Start[CodeLength[i]]++;
}

```

The code length adjustment process ensures that no code longer than the designated length will be generated. As long as the decompressor has the *CodeLength* array at hand, it can regenerate the codes.

18.4 Decompressor Design

The decompressor takes the compressed data as input and produces the original source data. The main tasks for the decompressor are decoding Huffman codes and restoring Pointers to the strings to which they point.

The following pseudo code describes the algorithm used in the design of a decompressor. The source code that illustrates an implementation of this design is listed in Appendix I.

```

WHILE not end of data DO
  IF at block boundary THEN
    Read in the Extra Set Code Length Array;
    Generate the Huffman code mapping table for the Extra Set;
    Read in and decode the Char&Len Set Code Length Array;
    Generate the Huffman code mapping table for the Char&Len Set;
    Read in the Position Set Code Length Array;
    Generate the Huffman code mapping table for the Position Set;
  ENDIF
  Get next code;
  Look the code up in the Char&Len Set code mapping table.
  Store the result as C;
  IF C < 256 (it represents an Original Character) THEN
    Output this character;
  ELSE (it represents a String Length)
    Transform C to be the actual String Length value;
    Get next code and look it up in the Position Set code mapping table, and
    with some additional transformation, store the result as P;
    Output C characters starting from the position "Current Position - P";
  ENDIF
ENDWHILE

```

18.5 Decompress Protocol

This section provides a detailed description of the `EFI_DECOMPRESS_PROTOCOL`.

EFI_DECOMPRESS_PROTOCOL

Summary

Provides a decompression service.

GUID

```
#define EFI_DECOMPRESS_PROTOCOL_GUID \
  {0xd8117cfe,0x94a6,0x11d4, \
   {0x9a,0x3a,0x00,0x90,0x27,0x3f,0xc1,0x4d}}
```

Protocol Interface Structure

```
typedef struct _EFI_DECOMPRESS_PROTOCOL {
  EFI_DECOMPRESS_GET_INFO      GetInfo;
  EFI_DECOMPRESS_DECOMPRESS    Decompress;
} EFI_DECOMPRESS_PROTOCOL;
```

Parameters

GetInfo

Given the compressed source buffer, this function retrieves the size of the uncompressed destination buffer and the size of the scratch buffer required to perform the decompression. It is the caller's responsibility to allocate the destination buffer and the scratch buffer prior to calling [EFI_DECOMPRESS_PROTOCOL.Decompress\(\)](#). See the [EFI_DECOMPRESS_PROTOCOL.GetInfo\(\)](#) function description.

Decompress

Decompresses a compressed source buffer into an uncompressed destination buffer. It is the caller's responsibility to allocate the destination buffer and a scratch buffer prior to making this call. See the [Decompress\(\)](#) function description.

Description

The `EFI_DECOMPRESS_PROTOCOL` provides a decompression service that allows a compressed source buffer in memory to be decompressed into a destination buffer in memory. It also requires a temporary scratch buffer to perform the decompression. The `GetInfo()` function retrieves the size of the destination buffer and the size of the scratch buffer that the caller is required to allocate. The `Decompress()` function performs the decompression. The scratch buffer can be freed after the decompression is complete.

EFI_DECOMPRESS_PROTOCOL.GetInfo()

Summary

Given a compressed source buffer, this function retrieves the size of the uncompressed buffer and the size of the scratch buffer required to decompress the compressed source buffer.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DECOMPRESS_GET_INFO) (
    IN  EFI_DECOMPRESS_PROTOCOL  *This,
    IN  VOID                      *Source,
    IN  UINT32                    SourceSize,
    OUT UINT32                    *DestinationSize,
    OUT UINT32                    *ScratchSize
);
```

Parameters

<i>This</i>	A pointer to the EFI_DECOMPRESS_PROTOCOL instance. Type EFI_DECOMPRESS_PROTOCOL is defined in Section 18.5 .
<i>Source</i>	The source buffer containing the compressed data.
<i>SourceSize</i>	The size, in bytes, of the source buffer.
<i>DestinationSize</i>	A pointer to the size, in bytes, of the uncompressed buffer that will be generated when the compressed buffer specified by <i>Source</i> and <i>SourceSize</i> is decompressed.
<i>ScratchSize</i>	A pointer to the size, in bytes, of the scratch buffer that is required to decompress the compressed buffer specified by <i>Source</i> and <i>SourceSize</i> .

Description

The **GetInfo()** function retrieves the size of the uncompressed buffer and the temporary scratch buffer required to decompress the buffer specified by *Source* and *SourceSize*. If the size of the uncompressed buffer or the size of the scratch buffer cannot be determined from the compressed data specified by *Source* and *SourceData*, then **EFI_INVALID_PARAMETER** is returned. Otherwise, the size of the uncompressed buffer is returned in *DestinationSize*, the size of the scratch buffer is returned in *ScratchSize*, and **EFI_SUCCESS** is returned.

The **GetInfo()** function does not have scratch buffer available to perform a thorough checking of the validity of the source data. It just retrieves the “Original Size” field from the beginning bytes of the source data and output it as *DestinationSize*. And *ScratchSize* is specific to the decompression implementation.

Status Codes Returned

EFI_SUCCESS	The size of the uncompressed data was returned in <i>DestinationSize</i> and the size of the scratch buffer was returned in <i>ScratchSize</i> .
EFI_INVALID_PARAMETER	The size of the uncompressed data or the size of the scratch buffer cannot be determined from the compressed data specified by <i>Source</i> and <i>SourceSize</i> .

EFI_DECOMPRESS_PROTOCOL.Decompress()

Summary

Decompresses a compressed source buffer.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DECOMPRESS_DECOMPRESS) (
    IN    EFI_DECOMPRESS_PROTOCOL  *This,
    IN    VOID                      *Source,
    IN    UINT32                    SourceSize,
    IN OUT VOID                     *Destination,
    IN    UINT32                    DestinationSize,
    IN OUT VOID                     *Scratch,
    IN    UINT32                    ScratchSize
);
```

Parameters

<i>This</i>	A pointer to the EFI_DECOMPRESS_PROTOCOL instance. Type EFI_DECOMPRESS_PROTOCOL is defined in Section 18.5 .
<i>Source</i>	The source buffer containing the compressed data.
<i>SourceSize</i>	The size of source data.
<i>Destination</i>	On output, the destination buffer that contains the uncompressed data.
<i>DestinationSize</i>	The size of the destination buffer. The size of the destination buffer needed is obtained from EFI_DECOMPRESS_PROTOCOL.GetInfo() .
<i>Scratch</i>	A temporary scratch buffer that is used to perform the decompression.
<i>ScratchSize</i>	The size of scratch buffer. The size of the scratch buffer needed is obtained from GetInfo() .

Description

The **Decompress()** function extracts decompressed data to its original form.

This protocol is designed so that the decompression algorithm can be implemented without using any memory services. As a result, the **Decompress()** function is not allowed to call [EFI_BOOT_SERVICES.AllocatePool\(\)](#) or [EFI_BOOT_SERVICES.AllocatePages\(\)](#) in its implementation. It is the caller's responsibility to allocate and free the *Destination* and *Scratch* buffers.

If the compressed source data specified by *Source* and *SourceSize* is successfully decompressed into *Destination*, then **EFI_SUCCESS** is returned. If the compressed source

data specified by *Source* and *SourceSize* is not in a valid compressed data format, then **EFI_INVALID_PARAMETER** is returned.

Status Codes Returned

EFI_SUCCESS	Decompression completed successfully, and the uncompressed buffer is returned in <i>Destination</i> .
EFI_INVALID_PARAMETER	The source buffer specified by <i>Source</i> and <i>SourceSize</i> is corrupted (not in a valid compressed format).

Protocols — ACPI Protocols

EFI_ACPI_TABLE_PROTOCOL

Summary

This protocol may be used to install or remove an ACPI table from a platform.

GUID

```
#define EFI_ACPI_TABLE_PROTOCOL_GUID \
  {0xffe06bdd, 0x6107, 0x46a6, \
   {0x7b, 0xb2, 0x5a, 0x9c, 0x7e, 0xc5, 0x27, 0x5c}}
```

Protocol Interface Structure

```
typedef struct _EFI_ACPI_TABLE_PROTOCOL {
  EFI_ACPI_TABLE_INSTALL_ACPI_TABLE   InstallAcpiTable;
  EFI_ACPI_TABLE_UNINSTALL_ACPI_TABLE UninstallAcpiTable;
} EFI_ACPI_TABLE_PROTOCOL;
```

Parameters

InstallAcpiTable Installs an ACPI table into the system.

UninstallAcpiTable Removes a previously installed ACPI table from the system.

Description

The **EFI_ACPI_TABLE_PROTOCOL** provides the ability for a component to install and uninstall ACPI tables from a platform.

EFI_ACPI_TABLE_PROTOCOL.InstallAcpiTable()

Summary

Installs an ACPI table into the RSDT/XSDT.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_ACPI_TABLE_INSTALL_ACPI_TABLE) (
    IN EFI_ACPI_TABLE_PROTOCOL *This,
    IN VOID *AcpiTableBuffer,
    IN UINTN AcpiTableBufferSize,
    OUT UINTN *TableKey,
);
```

Parameters

This A pointer to a [EFI ACPI TABLE PROTOCOL](#).

AcpiTableBuffer A pointer to a buffer containing the ACPI table to be installed.

AcpiTableBufferSize Specifies the size, in bytes, of the *AcpiTableBuffer* buffer.

TableKey Returns a key to refer to the ACPI table.

Description

The **InstallAcpiTable()** function allows a caller to install an ACPI table. The ACPI table may either be a System Description Table or the FACS. For all tables except for the DSDT and FACS, a copy of the table will be linked by the RSDT/XSDT. For the FACS and DSDT, the pointer to a copy of the table will be updated in the FADT, if present.

To prevent namespace collision, ACPI tables may be created using UEFI ACPI table format. See [Appendix O](#). If this protocol is used to install a table with a signature already present in the system, the new table will not replace the existing table. It is a platform implementation decision to add a new table with a signature matching an existing table or disallow duplicate table signatures and return **EFI_ACCESS_DENIED**.

On successful output, *TableKey* is initialized with a unique key. Its value may be used in a subsequent call to **UninstallAcpiTable** to remove an ACPI table.

On successful output, the **EFI_ACPI_TABLE_PROTOCOL** will ensure that the checksum field is correct for both the RSDT/XSDT table and the copy of the table being installed that is linked by the RSDT/XSDT.

If an EFI application is running at the time of this call, the relevant **EFI_CONFIGURATION_TABLE** pointer to the RSDT is no longer considered valid.

Status Codes Returned

EFI_SUCCESS	The table was successfully inserted
-------------	-------------------------------------

EFI_INVALID_PARAMETER	The <i>AcpiTableBuffer</i> is NULL , the <i>TableKey</i> is NULL ;the <i>AcpiTableBufferSize</i> , and the size field embedded in the ACPI table pointed to by <i>AcpiTableBuffer</i> are not in sync.
EFI_OUT_OF_RESOURCES	Insufficient resources exist to complete the request.
EFI_ACCESS_DENIED	The table signature matches a table already present in the system and platform policy does not allow duplicate tables of this type.

EFI_ACPI_TABLE_PROTOCOL.UninstallAcpiTable()

Summary

Removes an ACPI table from the RSDT/XSDT.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_ACPI_TABLE_UNINSTALL_ACPI_TABLE) (
    IN EFI_ACPI_TABLE_PROTOCOL    *This,
    IN UINTN                       TableKey,
);
```

Parameters

This A pointer to a [EFI ACPI TABLE PROTOCOL](#).

TableKey Specifies the table to uninstall. The key was returned from **InstallAcpiTable()**.

Description

The **UninstallAcpiTable()** function allows a caller to remove an ACPI table. The routine will remove its reference from the RSDT/XSDT. A table is referenced by the TableKey parameter returned from a prior call to **InstallAcpiTable()**. If an EFI application is running at the time of this call, the relevant **EFI_CONFIGURATION_TABLE** pointer to the RSDT is no longer considered valid.

Status Codes Returned

EFI_SUCCESS	The table was successfully inserted
EFI_NOT_FOUND	TableKey does not refer to a valid key for a table entry.
EFI_OUT_OF_RESOURCES	Insufficient resources exist to complete the request.

Protocols — String Services

20.1 Unicode Collation Protocol

This section defines the Unicode Collation protocol. This protocol is used to allow code running in the boot services environment to perform lexical comparison functions on Unicode strings for given languages.

EFI_UNICODE_COLLATION_PROTOCOL

Summary

Is used to perform case-insensitive comparisons of strings.

GUID

```
#define EFI_UNICODE_COLLATION_PROTOCOL2_GUID \
    {0xa4c751fc, 0x23ae, 0x4c3e, \
     {0x92, 0xe9, 0x49, 0x64, 0xcf, 0x63, 0xf3, 0x49}}
```

Protocol Interface Structure

```
typedef struct {
    EFI_UNICODE_COLLATION_STRICOLL           StriColl;
    EFI_UNICODE_COLLATION_METAIMATCH        MetaiMatch;
    EFI_UNICODE_COLLATION_STRLWR           StrLwr;
    EFI_UNICODE_COLLATION_STRUPR           StrUpr;
    EFI_UNICODE_COLLATION_FATTOSTR         FatToStr;
    EFI_UNICODE_COLLATION_STRTOFAT         StrToFat;
    CHAR8                                   *SupportedLanguages;
} EFI_UNICODE_COLLATION_PROTOCOL;
```

Parameters

<i>StriColl</i>	Performs a case-insensitive comparison of two Null-terminated strings. See the StriColl() function description.
<i>MetaiMatch</i>	Performs a case-insensitive comparison between a Null-terminated pattern string and a Null-terminated string. The pattern string can use the ‘?’ wildcard to match any character, and the ‘*’ wildcard to match any substring. See the MetaiMatch() function description.
<i>StrLwr</i>	Converts all the characters in a Null-terminated string to lowercase characters. See the StrLwr() function description.
<i>StrUpr</i>	Converts all the characters in a Null-terminated string to uppercase characters. See the StrUpr() function description.

<i>FatToStr</i>	Converts an 8.3 FAT file name using an OEM character set to a Null-terminated string. See the FatToStr() function description.
<i>StrToFat</i>	Converts a Null-terminated string to legal characters in a FAT filename using an OEM character set. See the StrToFat() function description.
<i>SupportedLanguages</i>	A Null-terminated ASCII string array that contains one or more language codes. This array is specified in RFC 4646 format. See Appendix M for the format of language codes and language code arrays.

Description

The **EFI_UNICODE_COLLATION_PROTOCOL** is used to perform case-insensitive comparisons of strings.

One or more of the **EFI_UNICODE_COLLATION_PROTOCOL** instances may be present at one time. Each protocol instance can support one or more language codes. The language codes supported in the **EFI_UNICODE_COLLATION_PROTOCOL** are declared in *SupportedLanguages*.

The *SupportedLanguages* is a Null-terminated ASCII string array that contains one or more supported language codes. This is the list of language codes that this protocol supports. See [Appendix M](#) for the format of language codes and language code arrays.

The main motivation for this protocol is to help support file names in a file system driver. When a file is opened, a file name needs to be compared to the file names on the disk. In some cases, this comparison needs to be performed in a case-insensitive manner. In addition, this protocol can be used to sort files from a directory or to perform a case-insensitive file search.

EFI_UNICODE_COLLATION_PROTOCOL.StriColl()

Summary

Performs a case-insensitive comparison of two Null-terminated strings.

Prototype

```
typedef
INTN
(EFI_API *EFI_UNICODE_COLLATION_STRICOLL) (
    IN EFI_UNICODE_COLLATION_PROTOCOL  *This,
    IN CHAR16                          *s1,
    IN CHAR16                          *s2
);
```

Parameters

<i>This</i>	A pointer to the EFI_UNICODE_COLLATION_PROTOCOL instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.
<i>s1</i>	A pointer to a Null-terminated string.
<i>s2</i>	A pointer to a Null-terminated string.

Description

The **StriColl()** function performs a case-insensitive comparison of two Null-terminated strings. This function performs a case-insensitive comparison between the string *s1* and the string *s2* using the rules for the language codes that this protocol instance supports. If *s1* is equivalent to *s2*, then 0 is returned. If *s1* is lexically less than *s2*, then a negative number will be returned. If *s1* is lexically greater than *s2*, then a positive number will be returned. This function allows strings to be compared and sorted.

Status Codes Returned

0	s1 is equivalent to s2.
> 0	s1 is lexically greater than s2.
< 0	s1 is lexically less than s2.

EFI_UNICODE_COLLATION_PROTOCOL.MetaiMatch()

Summary

Performs a case-insensitive comparison of a Null-terminated pattern string and a Null-terminated string.

Prototype

```
typedef
BOOLEAN
(EFIAPI *EFI_UNICODE_COLLATION_METAIMATCH) (
    IN EFI_UNICODE_COLLATION_PROTOCOL  *This,
    IN CHAR16                          *String,
    IN CHAR16                          *Pattern
);
```

Parameters

<i>This</i>	A pointer to the EFI_UNICODE_COLLATION_PROTOCOL instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.
<i>String</i>	A pointer to a Null-terminated string.
<i>Pattern</i>	A pointer to a Null-terminated string.

Description

The **MetaiMatch()** function performs a case-insensitive comparison of a Null-terminated pattern string and a Null-terminated string.

This function checks to see if the pattern of characters described by *Pattern* are found in *String*. The pattern check is a case-insensitive comparison using the rules for the language codes that this protocol instance supports. If the pattern match succeeds, then **TRUE** is returned.

Otherwise **FALSE** is returned. The following syntax can be used to build the string *Pattern*:

*	Match 0 or more characters.
?	Match any one character.
[<char1><char2>...<charN>]	Match any character in the set.
[<char1>-<char2>]	Match any character between <char1> and <char2>.
<char>	Match the character <char>.

Following is an example pattern for English:

*.FW	Matches all strings that end in “.FW” or “.fw” or “.Fw” or “.fW.”
[a-z]	Match any letter in the alphabet.
[!@#\$\$%^&* ()]	Match any one of these symbols.
z	Match the character “z” or “Z.”
D?.*	Match the character “D” or “d” followed by any character followed by a “.” followed by any string.

Status Codes Returned

TRUE	Pattern was found in <i>String</i> .
FALSE	Pattern was not found in <i>String</i> .

EFI_UNICODE_COLLATION_PROTOCOL.StrLwr()

Summary

Converts all the characters in a Null-terminated string to lowercase characters.

Prototype

```
typedef
VOID
(EFI_API *EFI_UNICODE_COLLATION_STRLWR) (
    IN EFI_UNICODE_COLLATION_PROTOCOL *This,
    IN OUT CHAR16 *String
);
```

Parameters

<i>This</i>	A pointer to the EFI_UNICODE_COLLATION_PROTOCOL instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.
<i>String</i>	A pointer to a Null-terminated string.

Description

This function walks through all the characters in *String*, and converts each one to its lowercase equivalent if it has one. The converted string is returned in *String*.

EFI_UNICODE_COLLATION_PROTOCOL.StrUpr()

Summary

Converts all the characters in a Null-terminated string to uppercase characters.

Prototype

```
typedef
VOID
(EFIAPI *EFI_UNICODE_COLLATION_STRUPR) (
    IN EFI_UNICODE_COLLATION_PROTOCOL *This,
    IN OUT CHAR16 *String
);
```

Parameters

<i>This</i>	A pointer to the EFI_UNICODE_COLLATION_PROTOCOL instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.
<i>String</i>	A pointer to a Null-terminated string.

Description

This functions walks through all the characters in *String*, and converts each one to its uppercase equivalent if it has one. The converted string is returned in *String*.

EFI_UNICODE_COLLATION_PROTOCOL.FatToStr()

Summary

Converts an 8.3 FAT file name in an OEM character set to a Null-terminated string.

Prototype

```

typedef
VOID
(EFIAPI *EFI_UNICODE_COLLATION_FATTOSTR) (
    IN EFI_UNICODE_COLLATION_PROTOCOL  *This,
    IN UINTN                            FatSize,
    IN CHAR8                            *Fat,
    OUT CHAR16                          *String
);

```

Parameters

<i>This</i>	A pointer to the EFI_UNICODE_COLLATION_PROTOCOL instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.
<i>FatSize</i>	The size of the string <i>Fat</i> in bytes.
<i>Fat</i>	A pointer to a Null-terminated string that contains an 8.3 file name encoded using an 8-bit OEM character set.
<i>String</i>	A pointer to a Null-terminated string. The string must be allocated in advance to hold <i>FatSize</i> characters.

Description

This function converts the string specified by *Fat* with length *FatSize* to the Null-terminated string specified by *String*. The characters in *Fat* are from an OEM character set.

EFI_UNICODE_COLLATION_PROTOCOL.StrToFat()

Summary

Converts a Null-terminated string to legal characters in a FAT filename using an OEM character set.

Prototype

```
typedef
BOOLEAN
(EFIAPI *EFI_UNICODE_COLLATION_STRTOFAT) (
    IN EFI_UNICODE_COLLATION_PROTOCOL *This,
    IN CHAR16 *String,
    IN UINTN FatSize,
    OUT CHAR8 *Fat
);
```

Parameters

<i>This</i>	A pointer to the EFI_UNICODE_COLLATION_PROTOCOL instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.
<i>String</i>	A pointer to a Null-terminated string.
<i>FatSize</i>	The size of the string <i>Fat</i> in bytes.
<i>Fat</i>	A pointer to a string that contains the converted version of <i>String</i> using legal FAT characters from an OEM character set.

Description

This function converts the characters from *String* into legal FAT characters in an OEM character set and stores then in the string *Fat*. This conversion continues until either *FatSize* bytes are stored in *Fat*, or the end of *String* is reached. The characters ‘.’ (period) and ‘ ’ (space) are ignored for this conversion. Characters that map to an illegal FAT character are substituted with an ‘_’. If no valid mapping from a character to an OEM character is available, then it is also substituted with an ‘_’. If any of the character conversions are substituted with a ‘_’, then **TRUE** is returned. Otherwise **FALSE** is returned.

Status Codes Returned

TRUE	One or more conversions failed and were substituted with ‘_’.
FALSE	None of the conversions failed.

20.2 Regular Expression Protocol

This section defines the Regular Expression Protocol. This protocol is used to match Unicode strings against Regular Expression patterns.

EFI_REGULAR_EXPRESSION_PROTOCOL

Summary

GUID

```
#define EFI_REGULAR_EXPRESSION_PROTOCOL_GUID \
    { 0xB3F79D9A, 0x436C, 0xDC11, \
      { 0xB0, 0x52, 0xCD, 0x85, 0xDF, 0x52, 0x4C, 0xE6 } }
```

Protocol Interface Structure

```
typedef struct {
    EFI_REGULAR_EXPRESSION_MATCH    MatchString;
    EFI_REGULAR_EXPRESSION_GET_INFO GetInfo;
} EFI_REGULAR_EXPRESSION_PROTOCOL;
```

Parameters

<i>MatchString</i>	Search the input string for anything that matches the regular expression.
<i>GetInfo</i>	Returns information about the regular expression syntax types supported by the implementation.

EFI_REGULAR_EXPRESSION_PROTOCOL.MatchString()

Summary

Checks if the input string matches to the regular expression pattern.

Prototype

```
typedef
EFI_STATUS
EFI_API *EFI_REGULAR_EXPRESSION_MATCH) (
    IN      EFI_REGULAR_EXPRESSION_PROTOCOL *This,
    IN      CHAR16                          *String,
    IN      CHAR16                          *Pattern,
    IN      EFI_REGEX_SYNTAX_TYPE           *SyntaxType, OPTIONAL
    OUT     BOOLEAN                          *Result,
    OUT     EFI_REGEX_CAPTURE               **Captures, OPTIONAL
    OUT     UINTN                            *CapturesCount
);
```

Parameters

<i>This</i>	A pointer to the EFI_REGULAR_EXPRESSION_PROTOCOL instance. Type EFI_REGULAR_EXPRESSION_PROTOCOL is defined in above.
<i>String</i>	A pointer to a NULL terminated string to match against the regular expression string specified by <i>Pattern</i> .
<i>Pattern</i>	A pointer to a NULL terminated string that represents the regular expression.
<i>SyntaxType</i>	A pointer to the EFI_REGEX_SYNTAX_TYPE that identifies the regular expression syntax type to use. May be NULL in which case the function will use its default regular expression syntax type.
<i>Result</i>	On return, points to TRUE if <i>String</i> fully matches against the regular expression <i>Pattern</i> using the regular expression <i>SyntaxType</i> . Otherwise, points to FALSE .
<i>Captures</i>	A Pointer to an array of EFI_REGEX_CAPTURE objects to receive the captured groups in the event of a match. The full sub-string match is put in <i>Captures</i> [0], and the results of N capturing groups are put in <i>Captures</i> [1:N]. If <i>Captures</i> is NULL, then this function doesn't allocate the memory for the array and does not build up the elements. It only returns the number of matching patterns in <i>CapturesCount</i> . If <i>Captures</i> is not NULL, this function returns a pointer to an array and builds up the elements in the array. <i>CapturesCount</i> is also updated to the number of matching patterns found. It is the caller's responsibility to free the memory pool in <i>Captures</i> and in each <i>CapturePtr</i> in the array elements.

CapturesCount On output, *CapturesCount* is the number of matching patterns found in *String*. Zero means no matching patterns were found in the string.

Description

The **MatchString()** function performs a matching of a Null-terminated input string with the NULL terminated pattern string. The pattern string syntax type is optionally identified in *SyntaxType*.

This function checks to see if *String* fully matches against the regular expression described by *Pattern*. The pattern check is performed using regular expression rules that are supported by this implementation, as indicated in the return value of *GetInfo* function. If the pattern match succeeds, then **TRUE** is returned in *Result*. Otherwise **FALSE** is returned.

Related Definitions

```
typedef struct {
    CONST CHAR16    *CapturePtr;
    UINTN          Length;
} EFI_REGEX_CAPTURE;
```

**CapturePtr* Pointer to the start of the captured sub-expression within matched *String*.

Length Length of captured sub-expression.

Status Codes Returned

EFI_SUCCESS	The regular expression string matching completed successfully.
EFI_UNSUPPORTED	The regular expression syntax specified by <i>SyntaxType</i> is not supported by this driver.
EFI_DEVICE_ERROR	The regular expression string matching failed due to a hardware or firmware error.
EFI_INVALID_PARAMETER	<i>String</i> , <i>Pattern</i> , <i>Result</i> , or <i>CapturesCount</i> is NULL.

EFI_REGULAR_EXPRESSION_PROTOCOL.GetInfo()

Summary

Returns information about the regular expression syntax types supported by the implementation.

Prototype

```
typedef
EFI_STATUS
EFI_API *EFI_REGULAR_EXPRESSION_GET_INFO) (
    IN      EFI_REGULAR_EXPRESSION_PROTOCOL *This,
    IN OUT UINTN                               *RegExSyntaxTypeListSize,
    OUT     EFI_REGEX_SYNTAX_TYPE             *RegExSyntaxTypeList
);
```

Parameters

This A pointer to the **EFI_REGULAR_EXPRESSION_PROTOCOL** instance.

RegExSyntaxTypeListSize

On input, the size in bytes of *RegExSyntaxTypeList*. On output with a return code of **EFI_SUCCESS**, the size in bytes of the data returned in *RegExSyntaxTypeList*. On output with a return code of **EFI_BUFFER_TOO_SMALL**, the size of *RegExSyntaxTypeList* required to obtain the list.

RegExSyntaxTypeList A caller-allocated memory buffer filled by the driver with one **EFI_REGEX_SYNTAX_TYPE** element for each supported regular expression syntax type. The list must not change across multiple calls to the same driver. The first syntax type in the list is the default type for the driver.

Description

This function returns information about supported regular expression syntax types. A driver implementing the **EFI_REGULAR_EXPRESSION_PROTOCOL** protocol need not support more than one regular expression syntax type, but shall support a minimum of one regular expression syntax type.

Related Definitions

```
typedef EFI_GUID EFI_REGEX_SYNTAX_TYPE;
```

Status Codes Returned

EFI_SUCCESS	The regular expression syntax types list was returned successfully.
EFI_UNSUPPORTED	The service is not supported by this driver.
EFI_DEVICE_ERROR	The list of syntax types could not be retrieved due to a hardware or firmware error.
EFI_BUFFER_TOO_SMALL	The buffer <i>RegExSyntaxTypeList</i> is too small to hold the result.
EFI_INVALID_PARAMETER	<i>RegExSyntaxTypeListSize</i> is NULL.

20.2.1 EFI Regular Expression Syntax Type Definitions

Summary

This sub-section provides **EFI_GUID** values for a selection of **EFI_REGULAR_EXPRESSION_PROTOCOL** syntax types. The types listed are optional, not meant to be exhaustive and may be augmented by vendors or other industry standards.

Prototype

For regular expression rules specified in the POSIX Extended Regular Expression (ERE) Syntax:

```
#define EFI_REGEX_SYNTAX_TYPE_POSIX_EXTENDED_GUID \
    {0x5F05B20F, 0x4A56, 0xC231, \
     { 0xFA, 0x0B, 0xA7, 0xB1, 0xF1, 0x10, 0x04, 0x1D }}
```

For regular expression rules specified in the Perl standard:

```
#define EFI_REGEX_SYNTAX_TYPE_PERL_GUID \
    {0x63E60A51, 0x497D, 0xD427, \
     { 0xC4, 0xA5, 0xB8, 0xAB, 0xDC, 0x3A, 0xAE, 0xB6 }}
```

For regular expression rules specified in the ECMA 262 Specification:

```
#define EFI_REGEX_SYNTAX_TYPE_ECMA_262_GUID \
    { 0x9A473A4A, 0x4CEB, 0xB95A, 0x41, \
     { 0x5E, 0x5B, 0xA0, 0xBC, 0x63, 0x9B, 0x2E }}
```

(See Appendix Q for more information.)

EFI Byte Code Virtual Machine

This section defines an EFI Byte Code (EBC) Virtual Machine that can provide platform- and processor-independent mechanisms for loading and executing EFI device drivers.

21.1 Overview

The current design for option ROMs that are used in personal computer systems has been in place since 1981. Attempts to change the basic design requirements have failed for a variety of reasons. The EBC Virtual Machine described in this chapter is attempting to help achieve the following goals:

- Abstract and extensible design
- Processor independence
- OS independence
- Build upon existing specifications when possible
- Facilitate the removal of legacy infrastructure
- Exclusive use of EFI Services

One way to satisfy many of these goals is to define a pseudo or virtual machine that can interpret a predefined instruction set. This will allow the virtual machine to be ported across processor and system architectures without changing or recompiling the option ROM. This specification defines a set of machine level instructions that can be generated by a C compiler.

The following sections are a detailed description of the requirements placed on future option ROMs.

21.1.1 Processor Architecture Independence

Option ROM images shall be independent of supported 32-bit and supported 64-bit architectures. In order to abstract the architectural differences between processors option ROM images shall be EBC. This model is presented below:

- 64-bit C source code
- The EFI EBC image is the flashed image
- The system BIOS implements the EBC interpreter
- The interpreter handles 32 vs. 64 bit issues

Current Option ROM technology is processor dependent and heavily reliant upon the existence of the PC-AT infrastructure. These dependencies inhibit the evolution of both hardware and software under the veil of “backward compatibility.” A solution that isolates the hardware and support infrastructure through abstraction will facilitate the uninhibited progression of technology.

21.1.2 OS Independent

Option ROMs shall not require or assume the existence of a particular OS.

21.1.3 EFI Compliant

Option ROM compliance with EFI requires (but is not limited to) the following:

- Little endian layout
- Single-threaded model with interrupt polling if needed
- Where EFI provides required services, EFI is used exclusively. These include:
 - Console I/O
 - Memory Management
 - Timer services
 - Global variable access
- When an Option ROM provides EFI services, the EFI specification is strictly followed:
 - Service/protocol installation
 - Calling conventions
 - Data structure layouts
 - Guaranteed return on services

21.1.4 Coexistence of Legacy Option ROMs

The infrastructure shall support coexistent Legacy Option ROM and EBC Option ROM images. This case would occur, for example, when a Plug and Play Card has both Legacy and EBC Option ROM images flashed. The details of the mechanism used to select which image to load is beyond the scope of this document. Basically, a legacy System BIOS would not recognize an EBC Option ROM and therefore would never load it. Conversely, an EFI Firmware Boot Manager would only load images that it supports.

The EBC Option ROM format must utilize a legacy format to the extent that a Legacy System BIOS can:

- Determine the type of the image, in order to ignore the image. The type must be incompatible with currently defined types.
- Determine the size of the image, in order to skip to the next image.

21.1.5 Relocatable Image

An EBC option ROM image shall be eligible for placement in any system memory area large enough to accommodate it.

Current option ROM technology requires images to be shadowed in system memory address range 0xC0000 to 0xEFFFF on a 2048 byte boundary. This dependency not only limits the number of Option ROMs, it results in unused memory fragments up to 2 KiB.

21.1.6 Size Restrictions Based on Memory Available

EBC option ROM images shall not be limited to a predetermined fixed maximum size.

Current option ROM technology limits the size of a preinitialization option ROM image to 128 KiB (126 KiB actual). Additionally, in the DDIM an image is not allowed to grow during initialization. It is inevitable that 64-bit solutions will increase in complexity and size. To avoid revisiting this issue, EBC option ROM size is only limited by available system memory. EFI memory allocation services allow device drivers to claim as much memory as they need, within limits of available system memory.

The PCI specification limits the size of an image stored in an option ROM to 16 MB. If the driver is stored on the hard drive then the 16MB option ROM limit does not apply. In addition, the PE/COFF object format limits the size of images to 2 GB.

21.2 Memory Ordering

The term memory ordering refers to the order in which a processor issues reads (loads) and writes (stores) out onto the bus to system memory. The EBC Virtual Machine enforces strong memory ordering, where reads and writes are issued on the system bus in the order they occur in the instruction stream under all circumstances.

21.3 Virtual Machine Registers

The EBC virtual machine utilizes a simple register set. There are two categories of VM registers: general purpose registers and dedicated registers. All registers are 64-bits wide. There are eight (8) general-purpose registers (**R0-R7**), which are used by most EBC instructions to manipulate or fetch data. [Table 142](#) lists the general-purpose registers in the VM and the conventions for their usage during execution.

Table 142. General Purpose VM Registers

Index	Register	Description
0	R0	Points to the top of the stack
1-3	R1-R3	Preserved across calls
4-7	R4-R7	Scratch, not preserved across calls

Register **R0** is used as a stack pointer and is used by the [CALL](#), [RET](#), [PUSH](#), and [POP](#) instructions. The VM initializes this register to point to the incoming arguments when an EBC image is started or entered. This register may be modified like any other general purpose VM register using EBC instructions. Register **R7** is used for function return values.

Unlike the general-purpose registers, the VM dedicated registers have specific purposes. There are two dedicated registers: the instruction pointer (**IP**), and the flags (**Flags**) register. Specialized instructions provide access to the dedicated registers. These instructions reference the particular dedicated register by its assigned index value. [Table 143](#) lists the dedicated registers and their corresponding index values.

Table 143. Dedicated VM Registers

Index	Register	Description	
0	FLAGS		
		Bit	Description
		0	C = Condition code
		1	SS = Single step
		2..63	Reserved
1	IP	Points to current instruction	
2..7	Reserved	Not defined	

The VM **Flags** register contains VM status and context flags. [Table 144](#) lists the descriptions of the bits in the **Flags** register.

Table 144. VM Flags Register

Bit	Flag	Description
0	C	Condition code. Set to 1 if the result of the last compare was true, or set to 0 if the last compare was false. Used by conditional JMP instructions.
1	S	Single-step. If set, causes the VM to generate a single-step exception after executing each instruction. The bit is not cleared by the VM following the exception.
2..63	-	Reserved

The VM **IP** register is used as an instruction pointer and holds the address of the currently executing EBC instruction. The virtual machine will update the **IP** to the address of the next instruction on completion of the current instruction, and will continue execution from the address indicated in **IP**. The **IP** register can be moved into any general-purpose register (**R0-R7**). Data manipulation and data movement instructions can then be used to manipulate the value. The only instructions that may modify the **IP** are the [JMP](#), [CALL](#), and [RET](#) instructions. Since the instruction set is designed to use words as the minimum instruction entity, the low order bit (bit 0) of **IP** is always cleared to 0. If a JMP, CALL, or RET instruction causes bit 0 of **IP** to be set to 1, then an alignment exception occurs.

21.4 Natural Indexing

The natural indexing mechanism is the critical functionality that enables EBC to be executed unchanged on 32- or 64-bit systems. Natural indexing is used to specify the offset of data relative to a base address. However, rather than specifying the offset as a fixed number of bytes, the offset is encoded in a form that specifies the actual offset in two parts: a constant offset, and an offset specified as a number of natural units (where one natural unit = sizeof(VOID *)). These two values are used to compute the actual offset to data at runtime. When the VM decodes an index during execution, the resultant offset is computed based on the natural processor size. The encoded

indexes themselves may be 16, 32, or 64 bits in size. [Table 145](#) describes the fields in a natural index encoding.

Table 145. Index Encoding

Bit #	Description
N	Sign bit (sign), most significant bit
N-3..N-1	Bits assigned to natural units (w)
A..N-4	Constant units (c)
0..A-1	Natural units (n)

As shown in [Table 145](#), for a given encoded index, the most significant bit (bit N) specifies the sign of the resultant offset after it has been calculated. The sign bit is followed by three bits (N-3..N-1) that are used to compute the width of the natural units field (n). The value (w) from this field is multiplied by the index size in bytes to determine the actual width (A) of the natural units field (n). Once the width of the natural units field has been determined, then the natural units (n) and constant units (c) can be extracted. The offset is then calculated at runtime according to the following equation:

$$\text{Offset} = (c + n * (\text{sizeof}(\text{VOID} *))) * \text{sign}$$

The following sections describe each of these fields in more detail.

21.4.1 Sign Bit

The sign bit determines the sign of the index once the offset calculation has been performed. All index computations using “n” and “c” are done with positive numbers, and the sign bit is only used to set the sign of the final offset computed.

21.4.2 Bits Assigned to Natural Units

This 3-bit field that is used to determine the width of the natural units field. The units vary based on the size of the index according to [Table 146](#). For example, for a 16-bit index, the value contained in this field would be multiplied by 2 to get the actual width of the natural-units field.

Table 146. Index Size in Index Encoding

Index Size	Units
16 bits	2 bits
32 bits	4 bits
64 bits	8 bits

21.4.3 Constant

The constant is the number of bytes in the index that do not scale with processor size. When the index is a 16-bit value, the maximum constant is 4095. This index is achieved when the bits assigned to natural units is 0.

21.4.4 Natural Units

Natural units are used when a structure has fields that can vary with the architecture of the processor. Fields that precipitate the use of natural units include pointers and EFI INTN and UINTN data types. The size of one pointer or INTN/UINTN equals one natural unit. The natural units field in an index encoding is a count of the number of natural fields whose sizes (in bytes) must be added to determine a field offset.

As an example, assume that a given EBC instruction specifies a 16-bit index of 0xA048. This breaks down into:

- Sign bit (bit 15) = 1 (negative offset)
- Bits assigned to natural units (w, bits 14-12) = 2. Multiply by index size in bytes = $2 \times 2 = 4$ (A)
- $c = \text{bits } 11-4 = 4$
- $n = \text{bits } 3-0 = 8$

On a 32-bit machine, the offset is then calculated to be:

- Offset = $(4 + 8 * 4) * -1 = -36$
- On a 64-bit machine, the offset is calculated to be:
- Offset = $(4 + 8 * 8) * -1 = -68$

21.5 EBC Instruction Operands

The VM supports an EBC instruction set that performs data movement, data manipulation, branching, and other miscellaneous operations typical of a simple processor. Most instructions operate on two operands, and have the general form:

INSTRUCTION Operand1, Operand2

Typically, instruction operands will be one of the following:

- Direct
- Indirect
- Indirect with index
- Immediate

The following subsections explain these operands.

21.5.1 Direct Operands

When a direct operand is specified for an instruction, the data to operate upon is contained in one of the VM general-purpose registers **R0-R7**. Syntactically, an example of direct operand mode could be the [ADD](#) instruction:

ADD64 R1, R2

This form of the instruction utilizes two direct operands. For this particular instruction, the VM would take the contents of register **R2**, add it to the contents of register **R1**, and store the result in register **R1**.

21.5.2 Indirect Operands

When an indirect operand is specified, a VM register contains the address of the operand data. This is sometimes referred to as register indirect, and is indicated by prefixing the register operand with “@.” Syntactically, an example of an indirect operand mode could be this form of the ADD instruction:

```
ADD32 R1, @R2
```

For this instruction, the VM would take the 32-bit value at the address specified in **R2**, add it to the contents of register **R1**, and store the result in register **R1**.

21.5.3 Indirect with Index Operands

When an indirect with index operand is specified, the address of the operand is computed by adding the contents of a register to a decoded natural index that is included in the instruction. Typically with indexed addressing, the base address will be loaded in the register and an index value will be used to indicate the offset relative to this base address. Indexed addressing takes the form

```
@R1 (+n, +c)
```

where:

- **R₁** is one of the general-purpose registers (**R0-R7**) which contains the base address
- **+n** is a count of the number of “natural” units offset. This portion of the total offset is computed at runtime as $(n * \text{sizeof}(\text{VOID} *))$
- **+c** is a byte offset to add to the natural offset to resolve the total offset

The values of **n** and **c** can be either positive or negative, though they must both have the same sign. These values get encoded in the indexes associated with EBC instructions as shown in [Table 145](#). Indexes can be 16-, 32-, or 64-bits wide depending on the instruction. An example of indirect with index syntax would be:

```
ADD32 R1, @R2 (+1, +8)
```

This instruction would take the address in register **R2**, add $(8 + 1 * \text{sizeof}(\text{VOID} *))$, read the 32-bit value at the address, add the contents of **R1** to the value, and store the result back to **R1**.

21.5.4 Immediate Operands

Some instructions support an immediate operand, which is simply a value included in the instruction encoding. The immediate value may or may not be sign extended, depending on the particular instruction. One instruction that supports an immediate operand is [MOVI](#). An example usage of this instruction is:

```
MOVIww R1, 0x1234
```

This instruction moves the immediate value 0x1234 directly into VM register **R1**. The immediate value is contained directly in the encoding for the MOVI instruction.

21.6 EBC Instruction Syntax

Most EBC instructions have one or more variations that modify the size of the instruction and/or the behavior of the instruction itself. These variations will typically modify an instruction in one or more of the following ways:

- The size of the data being operated upon
- The addressing mode for the operands
- The size of index or immediate data
- To represent these variations syntactically in this specification the following conventions are used:
 - Natural indexes are indicated with the “Index” keyword, and may take the form of “Index16,” “Index32,” or “Index64” to indicate the size of the index value supported. Sometimes the form Index16|32|64 is used here, which is simply a shorthand notation for Index16|Index32|Index64. A natural index is encoded per [Table 145](#) and is resolved at runtime.
 - Immediate values are indicated with the “Immed” keyword, and may take the form of “Immed16,” “Immed32,” or “Immed64” to indicate the size of the immediate value supported. The shorthand notation Immed16|32|64 is sometimes used when different size immediate values are supported.
 - Terms in brackets [] are required.
 - Terms in braces { } are optional.
 - Alternate terms are separated by a vertical bar |.
 - The form R₁ and R₂ represent Operand 1 register and Operand 2 register respectfully, and can typically be any VM general-purpose register **R0-R7**.
 - Within descriptions of the instructions, brackets [] enclosing a register and/or index indicate that the contents of the memory pointed to by the enclosed contents are used.

21.7 Instruction Encoding

Most EBC instructions take the form:

INSTRUCTION R₁, R₂ Index|Immed

For those instructions that adhere to this form, the binary encoding for the instruction will typically consist of an opcode byte, followed by an operands byte, followed by two or more bytes of immediate or index data. Thus the instruction stream will be:

(1 Byte Opcode) + (1 Byte Operands) + (Immediate data|Index data)

21.7.1 Instruction Opcode Byte Encoding

The first byte of an instruction is the opcode byte, and an instruction’s actual opcode value consumes 6 bits of this byte. The remaining two bits will typically be used to indicate operand sizes and/or presence or absence of index or immediate data. [Table 147](#) defines the bits in the opcode byte for most instructions, and their usage.

Table 147. Opcode Byte Encoding

Bit	Sym	Description
6..7	Modifiers	One or more of: Index or immediate data present/absent Operand size Index or immediate data size
0..5	Op	Instruction opcode

For those instructions that use bit 7 to indicate the presence of an index or immediate data and bit 6 to indicate the size of the index or immediate data, if bit 7 is 0 (no immediate data), then bit 6 is ignored by the VM. Otherwise, unless otherwise specified for a given instruction, setting unused bits in the opcode byte results in an instruction encoding exception when the instruction is executed. Setting the modifiers field in the opcode byte to reserved values will also result in an instruction encoding exception.

21.7.2 Instruction Operands Byte Encoding

The second byte of most encoded instructions is an operand byte, which encodes the registers for the instruction operands and whether the operands are direct or indirect. [Table 148](#) defines the encoding for the operand byte for these instructions. Unless otherwise specified for a given instruction, setting unused bits in the operand byte results in an instruction encoding exception when the instruction is executed. Setting fields in the operand byte to reserved values will also result in an instruction encoding exception.

Table 148. Operand Byte Encoding

Bit	Description
7	0 = Operand 2 is direct 1 = Operand 2 is indirect
4..6	Operand 2 register
3	0 = Operand 1 is direct 1 = Operand 1 is indirect
0..2	Operand 1 register

21.7.3 Index/Immediate Data Encoding

Following the operand bytes for most instructions is the instruction's immediate data. The immediate data is, depending on the instruction and instruction encoding, either an unsigned or signed literal value, or an index encoded using natural encoding. In either case, the size of the immediate data is specified in the instruction encoding.

For most instructions, the index/immediate value in the instruction stream is interpreted as a signed immediate value if the register operand is direct. This immediate value is then added to the contents of the register to compute the instruction operand. If the register is indirect, then the data is usually interpreted as a natural index (see [Section 21.4](#)) and the computed index value is added to the contents of the register to get the address of the operand.

21.8 EBC Instruction Set

The following sections describe each of the EBC instructions in detail. Information includes an assembly-language syntax, a description of the instruction functionality, binary encoding, and any limitations or unique behaviors of the instruction.

ADD

Syntax

ADD[32|64] {**@**}R₁, {**@**}R₂ {**Index16|Immed16**}

Description

Adds two signed operands and stores the result to Operand 1. The operation can be performed on either 32-bit (ADD32) or 64-bit (ADD64) operands.

Operation

Operand 1 <= **Operand 1** + **Operand 2**

Table 149. ADD Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x0C
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index and the Operand 2 value is fetched from memory as a signed value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the R₂ register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is ADD32 and Operand 1 is direct, then the result is stored back to the Operand 1 register with the upper 32 bits cleared.

AND

Syntax

AND [32|64] {**@**}R₁, {**@**}R₂ {**Index16|Immed16**}

Description

Performs a logical AND operation on two operands and stores the result to Operand 1. The operation can be performed on either 32-bit (AND32) or 64-bit (AND64) operands.

Operation

Operand 1 <= **Operand 1 AND Operand 2**

Table 150. AND Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x14
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as an unsigned value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is AND32 and Operand 1 is direct, then the result is stored to the Operand 1 register with the upper 32 bits cleared.

ASHR

Syntax

ASHR[32|64] {**@**}R₁, {**@**}R₂ {**Index16|Immed16**}

Description

Performs an arithmetic right-shift of a signed 32-bit (ASHR32) or 64-bit (ASHR64) operand and stores the result back to Operand 1

Operation

Operand 1 <= **Operand 1** **SHIFT-RIGHT** **Operand 2**

Table 151. ASHR Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x19
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as a signed value at address [R₂+ Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is ASHR32, and Operand 1 is direct, then the result is stored back to the Operand 1 register with the upper 32 bits cleared.

BREAK

Syntax

BREAK [**break code**]

Description

The BREAK instruction is used to perform special processing by the VM. The break code specifies the functionality to perform.

BREAK 0 – Runaway program break. This indicates that the VM is likely executing code from cleared memory. This results in a bad break exception.

BREAK 1 – Get virtual machine version. This instruction returns the 64-bit virtual machine revision number in VM register **R7**. The encoding is shown in [Table 152](#) and [Table 153](#). A VM that conforms to this version of the specification should return a version number of 0x00010000.

Table 152. VM Version Format

Bits	Description
63-32	Reserved = 0
31..16	VM major version
15..0	VM minor version

BREAK 3 – Debug breakpoint. Executing this instruction results in a debug break exception. If a debugger is attached or available, then it may halt execution of the image.

BREAK 4 – System call. There are no system calls supported for use with this break code, so the VM will ignore the instruction and continue execution at the following instruction.

BREAK 5 – Create thunk. This causes the interpreter to create a thunk for the EBC entry point whose 32-bit IP-relative offset is stored at the 64-bit address in VM register **R7**. The interpreter then replaces the contents of the memory location pointed to by **R7** to point to the newly created thunk. Since all EBC IP-relative offsets are relative to the next instruction or data object, the original offset is off by 4, so must be incremented by 4 to get the actual address of the entry point.

BREAK 6 – Set compiler version. An EBC C compiler can insert this break instruction into an executable to set the compiler version used to build an EBC image. When the VM executes this instruction it takes the compiler version from register **R7** and may perform version compatibility checking. The compiler version number follows the same format as the VM version number returned by the BREAK 1 instruction.

Table 153. BREAK Instruction Encoding

Byte	Description
0	Opcode = 0x00

Byte	Description
1	0 = Runaway program break 1 = Get virtual machine version 3 = Debug breakpoint 4 = System call 5 = Create thunk 6 = Set compiler version

Behaviors and Restrictions

- Executing an undefined BREAK code results in a bad break exception.
- Executing BREAK 0 results in a bad break exception.

CALL

Syntax

```
CALL32{EX}{a}  {@}R1  {Immed32 | Index32}
CALL64{EX}{a}  Immed64
```

Description

The CALL instruction pushes the address of the following instruction on the stack and jumps to a subroutine. The subroutine may be either EBC or native code, and may be to an absolute or **IP**-relative address. CALL32 is used to jump directly to EBC code within a given application, whereas CALLEX is used to jump to external code (either native or EBC), which requires thinking. Functionally, the CALL does the following:

```
R0 = R0 - 8;
PUSH64 ReturnAddress
if (Opcode.ImmedData64Bit) {
  if (Operands.EbcCall) {
    IP = Immed64;
  } else {
    NativeCall (Immed64);
  }
} else {
  if (Operand1 != R0) {
    Addr = Operand1;
  } else {
    Addr = Immed32;
  }
  if (Operands.EbcCall) {
    if (Operands.RelativeAddress) {
      IP += Addr + SizeOfThisInstruction;
    } else {
      IP = Addr
    }
  } else {
    if (Operands.RelativeAddress) {
      NativeCall (IP + Addr)
    } else {
      NativeCall (Addr)
    }
  }
}
```

Operation

```
R0 <= R0 - 16
[R0] <= IP + SizeOfThisInstruction
IP <= IP + SizeOfThisInstruction + Operand 1 (relative CALL)
IP <= Operand 1 (absolute CALL)
```

Table 154. CALL Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index data absent 1 = Immediate/index data present
	6	0 = CALL32 with 32-bit immediate data/index if present 1 = CALL64 with 64-bit immediate data
	0..5	Opcode = 0x03
1	Bit	Description
	6..7	Reserved = 0
	5	0 = Call to EBC 1 = Call to native code
	4	0 = Absolute address 1 = Relative address
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..5	Optional 32-bit index/immediate for CALL32	
2..9	Required 64-bit immediate data for CALL64	

BEHAVIOR AND RESTRICTIONS

- For the CALL32 forms, if Operand 1 is indirect, then the immediate data is interpreted as an index, and the Operand 1 value is fetched from memory address $[R_1 + \text{Index}_{32}]$.
- For the CALL32 forms, if Operand 1 is direct, then the immediate data is considered a signed immediate value and is added to the Operand 1 register contents such that $\text{Operand 1} = R_1 + \text{Immed}_{32}$.
- For the CALLEX forms, the VM must fix up the stack pointer and execute a call to native code in a manner compatible with the native code such that the callee is able to access arguments passed on the VM stack..
- For the CALLEX forms, the value returned by the callee should be returned in **R7**.
- For the CALL64 forms, the Operand 1 fields are ignored.
- If $\text{Byte7:Bit6} = 1$ (CALL64), then Byte1:Bit4 is assumed to be 0 (absolute address)
- For CALL32 forms, if Operand 1 register = **R0**, then the register operand is ignored and only the immediate data is used in the calculation of the call address.
- Prior to the call, the VM will decrement the stack pointer **R0** by 16 bytes, and store the 64-bit return address on the stack.
- Offsets for relative calls are relative to the address of the instruction following the CALL instruction.

CMP

Syntax

CMP[32|64][eq|lte|gte|ulte|ugte] R₁, {@}R₂ {Index16|Immed16}

Description

The CMP instruction is used to compare Operand 1 to Operand 2. Supported comparison modes are =, <=, >=, unsigned <=, and unsigned >=. The comparison size can be 32 bits (CMP32) or 64 bits (CMP64). The effect of this instruction is to set or clear the condition code bit in the **Flags** register per the comparison results. The operands are compared as signed values except for the CMPulte and CMPugte forms.

Operation

CMPEq: **Flags.C** <= (Operand 1 == Operand 2)
CMPlte: **Flags.C** <= (Operand 1 <= Operand 2)
CMPgte: **Flags.C** <= (Operand 1 >= Operand 2)
CMPulte: **Flags.C** <= (Operand 1 <= Operand 2) (unsigned)
CMPugte: **Flags.C** <= (Operand 1 >= Operand 2) (unsigned)

Table 155. CMP Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index data absent 1 = Immediate/index data present
	6	0 = 32-bit comparison 1 = 64-bit comparison
	0..5	Opcode 0x05 = CMPEq compare equal 0x06 = CMPlte compare signed less than/equal 0x07 = CMPgte compare signed greater than/equal 0x08 = CMPulte compare unsigned less than/equal 0x09 = CMPugte compare unsigned greater than/equal
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	Reserved = 0
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory address $[R_2 + \text{Index}16]$.
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the register contents such that $\text{Operand 2} = R_2 + \text{Immed}16$.
- Only register direct is supported for Operand 1.

CMPI

Syntax

```
CMPI [32 | 64] {w | d} {eq | lte | gte | ulte | ugte} {@}R1 {Index16},
    Immed16 | Immed32
```

Description

Compares two operands, one of which is an immediate value, for =, <=, >=, unsigned <=, or unsigned >=, and sets or clears the condition flag bit in the **Flags** register accordingly. Comparisons can be performed on a 32-bit (CMPI32) or 64-bit (CMPI64) basis. The size of the immediate data can be either 16 bits (CMPIw) or 32 bits (CMPId).

Operation

```
CMPIeq: Flags.C <= (Operand 1 == Operand 2)
CMPIlte: Flags.C <= (Operand 1 <= Operand 2)
CMPIgte: Flags.C <= (Operand 1 >= Operand 2)
CMPIulte: Flags.C <= (Operand 1 <= Operand 2)
CMPIugte: Flags.C <= (Operand 1 >= Operand 2)
```

Table 156. CMPI Instruction Encoding

BYTE	Description		
0	Bit	Description	
	7	0 = 16-bit immediate data 1 = 32-bit immediate data	
	6	0 = 32-bit comparison 1 = 64-bit comparison	
	0..5	Opcode	
		0x2D = CMPIeq compare equal 0x2E = CMPIlte compare signed less than/equal 0x2F = CMPIgte compare signed greater than/equal 0x30 = CMPIulte compare unsigned less than/equal 0x31 = CMPIugte compare unsigned greater than/equal	
1	Bit	Description	
	5..7	Reserved = 0	
	4	0 = Operand 1 index absent 1 = Operand 1 index present	
	3	0 = Operand 1 direct 1 = Operand 1 indirect	
	0..2	Operand 1	
2..3	Optional 16-bit Operand 1 index		
2..3/4..5	16-bit immediate data		
2..5/4..7	32-bit immediate data		

Behaviors and Restrictions

- The immediate data is fetched as a signed value.
- If the immediate data is smaller than the comparison size, then the immediate data is sign-extended appropriately.
- If Operand 1 is direct, and an Operand 1 index is specified, then an instruction encoding exception is generated.

DIV

Syntax

DIV[32|64] {**@**}R₁, {**@**}R₂ {**Index16**|**Immed16**}

Description

Performs a divide operation on two signed operands and stores the result to Operand 1. The operation can be performed on either 32-bit (DIV32) or 64-bit (DIV64) operands.

Operation

Operand 1 <= **Operand 1** / **Operand 2**

Table 157. DIV Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x10
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as a signed value at address [R₂+ Index16].
- If Operand 2 is direct, then the immediate data is considered a signed value and is added to the register contents such that Operand 2 = R₂ + Immed16
- If the instruction is DIV32 form, and Operand 1 is direct, then the upper 32 bits of the result are set to 0 before storing to the Operand 1 register.
- A divide-by-0 exception occurs if Operand 2 = 0.

DIVU

Syntax

DIVU[32|64] {**@**}R₁, {**@**}R₂ {**Index16**|**Immed16**}

Description

Performs a divide operation on two unsigned operands and stores the result to Operand 1. The operation can be performed on either 32-bit (DIVU32) or 64-bit (DIVU64) operands.

Operation

Operand 1 <= **Operand 1** / **Operand 2**

Table 158. DIVU Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x11
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the value is fetched from memory as an unsigned value at address [R₂+ Index16].
- If Operand 2 is direct, then the immediate data is considered an unsigned value and is added to the Operand 2 register contents such that Operand 2 = R₂ + Immed16
- For the DIVU32 form, if Operand 1 is direct then the upper 32 bits of the result are set to 0 before storing back to the Operand 1 register.
- A divide-by-0 exception occurs if Operand 2 = 0.

EXTNDB

Syntax

EXTNDB[32|64] {**@**}R₁, {**@**}R₂ {**Index16|Immed16**}

Description

Sign-extend a byte value and store the result to Operand 1. The byte can be signed extended to 32 bits (EXTNDB32) or 64 bits (EXTNDB64).

Operation

Operand 1 <= (sign extended) **Operand 2**

Table 159. EXTNDB Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x1A
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the byte Operand 2 value is fetched from memory as a signed value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value, is added to the signed-extended byte from the Operand 2 register, and the byte result is sign extended to 32 or 64 bits.
- If the instruction is EXTNDB32 and Operand 1 is direct, then the 32-bit result is stored in the Operand 1 register with the upper 32 bits cleared.

EXTNDD

Syntax

EXTNDD [32|64] {**@**}R₁, {**@**}R₂ {**Index16|Immed16**}

Description

Sign-extend a 32-bit Operand 2 value and store the result to Operand 1. The Operand 2 value can be extended to 32 bits (EXTNDD32) or 64 bits (EXTNDD64).

Operation

Operand 1 <= (sign extended) **Operand 2**

Table 160. EXTNDD Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x1C
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the 32-bit value is fetched from memory as a signed value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value such that Operand 2 = R₂ + Immed16, and the value is sign extended to 32 or 64 bits accordingly.
- If the instruction is EXTNDD32 and Operand 1 is direct, then the result is stored in the Operand 1 register with the upper 32 bits cleared.

EXTNDW

Syntax

EXTNDW[32|64] {**@**}R₁, {**@**}R₂ {**Index16|Immed16**}

Description

Sign-extend a 16-bit Operand 2 value and store the result back to Operand 1. The value can be signed extended to 32 bits (EXTNDW32) or 64 bits (EXTNDW64).

Operation

Operand 1 <= (sign extended) **Operand 2**

Table 161. EXTNDW Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x1B
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the word value is fetched from memory as a signed value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value such that Operand 2 = R₂ + Immed16, and the value is sign extended to 32 or 64 bits accordingly.
- If the instruction is EXTNDW32 and Operand 1 is direct, then the 32-bit result is stored in the Operand 1 register with the upper 32 bits cleared.

JMP

Syntax

```
JMP32{cs|cc} {@}R1 {Immed32|Index32}
JMP64{cs|cc} Immed64
```

Description

The JMP instruction is used to conditionally or unconditionally jump to a relative or absolute address and continue executing EBC instructions. The condition test is done using the condition bit in the VM **Flags** register. The JMP64 form only supports an immediate value that can be used for either a relative or absolute jump. The JMP32 form adds support for indirect addressing of the JMP offset or address. The JMP is implemented as:

```
if (ConditionMet) {
    if (Operand.RelativeJump) {
        IP += Operand1 + SizeOfThisInstruction;
    } else {
        IP = Operand1;
    }
}
```

Operation

```
IP <= Operand 1 (absolute address)
IP <= IP + SizeOfThisInstruction + Operand 1 (relative address)
```

Table 162. JMP Instruction Encoding

Byte	Description	
0	Bit	Description
	7	0 = Immediate/index data absent 1 = Immediate/index data present
	6	0 = JMP32 1 = JMP64
	0..5	Opcode = 0x01
1	Bit	Description
	7	0 = Unconditional jump 1 = Conditional jump
	6	0 = Jump if Flags.C is clear (cc) 1 = Jump if Flags.C is set (cs)
	5	Reserved = 0
	4	0 = Absolute address 1 = Relative address
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1

Byte	Description
2..5	Optional 32-bit immediate data/index for JMP32
2..9	64-bit immediate data for JMP64

Behaviors and Restrictions

- Operand 1 fields are ignored for the JMP64 forms
- If the instruction is JMP32, and Operand 1 register = **R0**, then the register contents are assumed to be 0.
- If the instruction is JMP32, and Operand 1 is indirect, then the immediate data is interpreted as an index, and the jump offset or address is fetched as a 32-bit signed value from address $[R_1 + \text{Index32}]$
- If the instruction is JMP32, and Operand 1 is direct, then the immediate data is considered a signed immediate value such that $\text{Operand 1} = R_1 + \text{Immed32}$
- If the jump is unconditional, then Byte1:Bit6 (condition) is ignored
- If the instruction is JMP64, and Byte0:Bit7 is clear (no immediate data), then an instruction encoding exception is generated.
- If the instruction is JMP32, and Operand 2 is indirect, then the Operand 2 value is read as a natural value from memory address $[R_1 + \text{Index32}]$
- An alignment check exception is generated if the jump is taken and the target address is odd.

JMP8

Syntax

JMP8{cs|cc} **Immed8**

Description

Conditionally or unconditionally jump to a relative offset and continue execution. The offset is a signed one-byte offset specified in the number of words. The offset is relative to the start of the following instruction.

Operation

IP = IP + SizeOfThisInstruction + (Immed8 * 2)

Table 163. JMP8 Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Unconditional jump 1 = Conditional jump
	6	0 = Jump if Flags.C is clear (cc) 1 = Jump if Flags.C is set (cs)
	0..5	Opcode = 0x02
1	Immediate data (signed word offset)	

Behaviors and Restrictions

- If the jump is unconditional, then Byte0:Bit6 (condition) is ignored

LOADSP

Syntax

LOADSP [**Flags**], **R₂**

Description

This instruction loads a VM dedicated register with the contents of a VM general-purpose register **R0-R7**. The dedicated register is specified by its index as shown in [Table 143](#).

Operation

Operand 1 \leftarrow **R₂**

Table 164. LOADSP Instruction Encoding

BYTE	Description	
0	Bit	Description
	6..7	Reserved = 0
	0..5	Opcode = 0x29
1	7	Reserved
	4..6	Operand 2 general purpose register
	3	Reserved
	0..2	Operand 1 dedicated register index

Behaviors and Restrictions

- Attempting to load any register (Operand 1) other than the **Flags** register results in an instruction encoding exception.
- Specifying a reserved dedicated register index results in an instruction encoding exception.
- If Operand 1 is the **Flags** register, then reserved bits in the **Flags** register are not modified by this instruction.

MOD

Syntax

MOD [32|64] {@}R₁, {@}R₂ {Index16|Immed16}

Description

Perform a modulus on two signed 32-bit (MOD32) or 64-bit (MOD64) operands and store the result to Operand 1.

Operation

Operand 1 <= **Operand 1** MOD **Operand 2**

Table 165. MOD Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x12
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as a signed value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value such that Operand 2 = R₂ + Immed16, and the value is sign extended to 32 or 64 bits accordingly.
- If Operand 2 = 0, then a divide-by-zero exception is generated.

MODU

Syntax

MODU[32|64] {**@**}R₁, {**@**}R₂ {**Index16|Immed16**}

Description

Perform a modulus on two unsigned 32-bit (MODU32) or 64-bit (MODU64) operands and store the result to Operand 1.

Operation

Operand 1 <= **Operand 1** MOD **Operand 2**

Table 166. MODU Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x13
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as an unsigned value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered an unsigned immediate value such that Operand 2 = R₂ + Immed16.
- If Operand 2 = 0, then a divide-by-zero exception is generated.

MOV

Syntax

```
MOV[b|w|d|q]{w|d} {@}R1 {Index16|32}, {@}R2 {Index16|32}
MOVqq {@}R1 {Index64}, {@}R2 {Index64}
```

Description

This instruction moves data from Operand 2 to Operand 1. Both operands can be indexed, though both indexes are the same size. In the instruction syntax for the first form, the first variable character indicates the size of the data move, which can be 8 bits (b), 16 bits (w), 32 bits (d), or 64 bits (q). The optional character indicates the presence and size of the index value(s), which may be 16 bits (w) or 32 bits (d). The MOVqq instruction adds support for 64-bit indexes.

Operation

```
Operand 1 <= Operand 2
```

Table 167. MOV Instruction Encoding

Byte	Description		
0	Bit	Description	
	7	0 = Operand 1 index absent 1 = Operand 1 index present	
	6	0 = Operand 2 index absent 1 = Operand 2 index present

	4..6	Operand 2	
	3	0 = Operand 1 direct 1 = Operand 1 indirect	
	0..2	Operand 1	
	2..3	Optional Operand 1 16-bit index	
	2..3/4..5	Optional Operand 2 16-bit index	
	2..5	Optional Operand 1 32-bit index	
	2..5/6..9	Optional Operand 2 32-bit index	

Byte	Description
2..9	Optional Operand 1 64-bit index (MOVqq)
2..9/10..17	Optional Operand 2 64-bit index (MOVqq)

Behaviors and Restrictions

- If an index is specified for Operand 1, and Operand 1 is direct, then an instruction encoding exception is generated.

MOVI

Syntax

MOVI [b|w|d|q] [w|d|q] {@}R₁ {Index16}, Immed16|32|64

Description

This instruction moves a signed immediate value to Operand 1. In the instruction syntax, the first variable character specifies the width of the move, which may be 8 bits (b), 16 bits (w), 32-bits (d), or 64 bits (q). The second variable character specifies the width of the immediate data, which may be 16 bits (w), 32 bits (d), or 64 bits (q).

Operation

Operand 1 <= **Operand 2**

Table 168. MOVI Instruction Encoding

BYTE	Description	
0	Bit	Description
	6..7	0 = Reserved 1 = Immediate data is 16 bits (w) 2 = Immediate data is 32 bits (d) 3 = Immediate data is 64 bits (q)
	0..5	Opcode = 0x37
1	Bit	Description
	7	Reserved = 0
	6	0 = Operand 1 index absent 1 = Operand 1 index present
	4..5	0 = 8 bit (b) move 1 = 16 bit (w) move 2 = 32 bit (d) move 3 = 64 bit (q) move
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit index	
2..3/4..5	16-bit immediate data	
2..5/4..7	32-bit immediate data	
2..9/4..11	64-bit immediate data	

Behaviors and Restrictions

- Specifying an index value with Operand 1 direct results in an instruction encoding exception.
- If the immediate data is smaller than the move size, then the value is sign-extended to the width of the move.

Unified Extensible Firmware Interface Specification

- If Operand 1 is a register, then the value is stored to the register with bits beyond the move size cleared.

MOVIn

Syntax

MOVIn[w|d|q] {@}R₁ {Index16}, Index16|32|64

Description

This instruction moves an indexed value of form (+n,+c) to Operand 1. The index value is converted from (+n, +c) format to a signed offset per the encoding described in [Table 145](#). The size of the Operand 2 index data can be 16 (w), 32 (d), or 64 (q) bits.

Operation

Operand 1 <= Operand 2 (index value)

Table 169. MOVIn Instruction Encoding

BYTE	Description	
0	Bit	Description
	6..7	0 = Reserved 1 = Operand 2 index value is 16 bits (w) 2 = Operand 2 index value is 32 bits (d) 3 = Operand 2 index value is 64 bits (q)
	0..5	Opcode = 0x38
1	Bit	Description
	7	Reserved
	6	0 = Operand 1 index absent 1 = Operand 1 index present
	4..5	Reserved = 0
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit Operand 1 index	
2..3/4..5	16-bit Operand 2 index	
2..5/4..7	32-bit Operand 2 index	
2..9/4..11	64-bit Operand 2 index	

Behaviors and Restrictions

- Specifying an Operand 1 index when Operand 1 is direct results in an instruction encoding exception.
- The Operand 2 index is sign extended to the size of the move if necessary.
- If the Operand 2 index size is smaller than the move size, then the value is truncated.
- If Operand 1 is direct, then the Operand 2 value is sign extended to 64 bits and stored to the Operand 1 register.

MOVn

Syntax

MOVn{w|d} {@}R₁ {Index16|32}, {@}R₂ {Index16|32}

Description

This instruction loads an unsigned natural value from Operand 2 and stores the value to Operand 1. Both operands can be indexed, though both operand indexes are the same size. The operand index(s) can be 16 bits (w) or 32 bits (d).

Operation

Operand1 <= (UINTN) Operand2

Table 170. MOVn Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 1 index absent 1 = Operand 1 index present
	6	0 = Operand 2 index absent 1 = Operand 2 index present
	0..5	0x32 = MOVnw opcode 0x33 = MOVnd opcode
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional Operand 1 16-bit index	
2..3/4..5	Optional Operand 2 16-bit index	
2..5	Optional Operand 1 32-bit index	
2..5/6..9	Optional Operand 2 32-bit index	

Behaviors and Restrictions

- If an index is specified for Operand 2, and Operand 2 register is direct, then the Operand 2 index value is added to the register contents such that Operand 2 = (UINTN)(R₂ + Index).
- If an index is specified for Operand 1, and Operand 1 is direct, then an instruction encoding exception is generated.
- If Operand 1 is direct, then the Operand 2 value will be 0-extended to 64 bits on a 32-bit machine before storing to the Operand 1 register.

MOVREL

Syntax

MOVREL[w|d|q] {**@**}R₁ {**Index16**}, **Immed16|32|64**

Description

This instruction fetches data at an **IP**-relative immediate offset (Operand 2) and stores the result to Operand 1. The offset is a signed offset relative to the following instruction. The fetched data is unsigned and may be 16 (w), 32 (d), or 64 (q) bits in size.

Operation

Operand 1 <= [**IP** + **SizeOfThisInstruction** + **Immed**]

Table 171. MOVREL Instruction Encoding

BYTE	Description	
0	Bit	Description
	6..7	0 = Reserved 1 = Immediate data is 16 bits (w) 2 = Immediate data is 32 bits (d) 3 = Immediate data is 64 bits (q)
	0..5	Opcod = 0x39
1	Bit	Description
	7	Reserved = 0
	6	0 = Operand 1 index absent 1 = Operand 1 index present
	4..5	Reserved = 0
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit Operand 1 index	
2..3/4..5	16-bit immediate offset	
2..5/4..7	32-bit immediate offset	
2..9/4..11	64-bit immediate offset	

Behaviors and Restrictions

- If an Operand 1 index is specified and Operand 1 is direct, then an instruction encoding exception is generated.

MOVsn

Syntax

MOVsn{w} {@}R₁, {Index16}, {@}R₂ {Index16|Immed16}

MOVsn{d} {@}R₁ {Index32}, {@}R₂ {Index32|Immed32}

Description

Moves a signed natural value from Operand 2 to Operand 1. Both operands can be indexed, though the indexes are the same size. Indexes can be either 16 bits (MOVsnw) or 32 bits (MOVsnd) in size.

Operation

Operand 1 <= Operand 2

Table 172. MOVsn Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 1 index absent 1 = Operand 1 index present
	6	0 = Operand 2 index/immediate data absent 1 = Operand 2 index/immediate data present
	0..5	0x25 = MOVsnw opcode 0x26 = MOVsnd opcode
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit Operand 1 index (MOVsnw)	
2..3/4..5	Optional 16-bit Operand 2 index (MOVsnw)	
2..5	Optional 32-bit Operand 1 index/immediate data (MOVsnd)	
2..5/6..9	Optional 32-bit Operand 2 index/immediate data (MOVsnd)	

Behaviors and Restrictions

- If Operand 2 is direct, and Operand 2 index/immediate data is specified, then the immediate value is read as a signed immediate value and is added to the contents of Operand 2 register such that $\text{Operand 2} = R_2 + \text{Immed}$.
- If Operand 2 is indirect, and Operand 2 index/immediate data is specified, then the immediate data is interpreted as an index and the Operand 2 value is fetched from memory as a signed value at address $[R_2 + \text{Index16}]$.

- If an index is specified for Operand 1, and Operand 1 is direct, then an instruction encoding exception is generated.
- If Operand 1 is direct, then the Operand 2 value is sign-extended to 64-bits on 32-bit native machines.

MUL

Syntax

MUL[32|64] {**@**}R₁, {**@**}R₂ {**Index16**|**Immed16**}

Description

Perform a signed multiply of two operands and store the result back to Operand 1. The operands can be either 32 bits (MUL32) or 64 bits (MUL64).

Operation

Operand 1 <= **Operand** * **Operand 2**

Table 173. MUL Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 2 immediate/index absent 1 = Operand 2 immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x0E
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit Operand 2 immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as a signed value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the Operand 2 register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is MUL32, and Operand 1 is direct, then the result is stored to Operand 1 register with the upper 32 bits cleared.

MULU

Syntax

MULU[32|64] {**@**}R₁, {**@**}R₂ {**Index16**|**Immed16**}

Description

Performs an unsigned multiply of two 32-bit (MULU32) or 64-bit (MULU64) operands, and stores the result back to Operand 1.

Operation

Operand 1 <= **Operand** * **Operand 2**

Table 174. MULU Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 2 immediate/index absent 1 = Operand 2 immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x0F
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as an unsigned value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the Operand 2 register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is MULU32 and Operand 1 is direct, then the result is written to the Operand 1 register with the upper 32 bits cleared.

NEG

Syntax

NEG[32|64] {**@**}R₁, {**@**}R₂ {**Index16**|**Immed16**}

Description

Multiply Operand 2 by negative 1, and store the result back to Operand 1. Operand 2 is a signed value and fetched as either a 32-bit (NEG32) or 64-bit (NEG64) value.

Operation

Operand 1 <= -1 * **Operand 2**

Table 175. NEG Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 2 immediate/index absent 1 = Operand 2 immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x0B
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as a signed value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the Operand 2 register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is NEG32 and Operand 1 is direct, then the result is stored in Operand 1 register with the upper 32-bits cleared.

NOT

Syntax

NOT[32|64] {**@**}R₁, {**@**}R₂ {**Index16|Immed16**}

Description

Performs a logical NOT operation on Operand 2, an unsigned 32-bit (NOT32) or 64-bit (NOT64) value, and stores the result back to Operand 1.

Operation

Operand 1 <= **NOT** **Operand 2**

Table 176. NOT Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 2 immediate/index absent 1 = Operand 2 immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x0A
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as an unsigned value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the Operand 2 register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is NOT32 and Operand 1 is a register, then the result is stored in the Operand 1 register with the upper 32 bits cleared.

OR

Syntax

OR[32|64] {**@**}R₁, {**@**}R₂ {**Index16**|**Immed16**}

Description

Performs a bit-wise OR of two 32-bit (OR32) or 64-bit (OR64) operands, and stores the result back to Operand 1.

Operation

Operand 1 <= **Operand 1** OR **Operand 2**

Table 177. OR Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 2 immediate/index absent 1 = Operand 2 immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x15
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as an unsigned value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the Operand 2 register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is OR32 and Operand 1 is direct, then the result is stored to Operand 1 register with the upper 32 bits cleared.

POP

Syntax

POP [32 | 64] {@}R₁ {Index16 | Immed16}

Description

This instruction pops a 32-bit (POP32) or 64-bit (POP64) value from the stack, stores the result to Operand 1, and adjusts the stack pointer **R0** accordingly.

Operation

Operand 1 <= [R0]
R0 <= **R0** + 4 (POP32)
R0 <= **R0** + 8 (POP64)

Table 178. POP Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x2C
1	Bit	Description
	7..4	Reserved = 0
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 1 is direct, and an index/immediate data is specified, then the immediate data is read as a signed value and is added to the value popped from the stack, and the result stored to the Operand 1 register.
- If Operand 1 is indirect, then the immediate data is interpreted as an index, and the value popped from the stack is stored to address [R₁ + Index16].
- If the instruction is POP32, and Operand 1 is direct, then the popped value is sign-extended to 64 bits before storing to the Operand 1 register.

POPn

Syntax

`POPn {@}R1 {Index16|Immed16}`

Description

Read an unsigned natural value from memory pointed to by stack pointer **R0**, adjust the stack pointer accordingly, and store the value back to Operand 1.

Operation

`Operand 1 <= (UINTN) [R0]`
`R0 <= R0 + sizeof (VOID *)`

Table 179. POPn Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	Reserved = 0
	0..5	Opcode = 0x36
1	Bit	Description
	7..4	Reserved = 0
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 1 is direct, and an index/immediate data is specified, then the immediate data is fetched as a signed value and is added to the value popped from the stack and the result is stored back to the Operand 1 register.
- If Operand 1 is indirect, and an index/immediate data is specified, then the immediate data is interpreted as a natural index and the value popped from the stack is stored at [R₁ + Index16].
- If Operand 1 is direct, and the instruction is executed on a 32-bit machine, then the result is stored to the Operand 1 register with the upper 32 bits cleared.

PUSH

Syntax

PUSH[32|64] {**@**}**R**₁ {**Index16|Immed16**}

Description

Adjust the stack pointer **R0** and store a 32-bit (PUSH32) or 64-bit (PUSH64) Operand 1 value on the stack.

Operation

R0 <= **R0** - 4 (PUSH32)

R0 <= **R0** - 8 (PUSH64)

[**R0**] <= **Operand 1**

Table 180. PUSH Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x2B
1	Bit	Description
	7..4	Reserved = 0
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 1 is direct, and an index/immediate data is specified, then the immediate data is read as a signed value and is added to the Operand 1 register contents such that $\text{Operand 1} = R_1 + \text{Immed16}$.
- If Operand 1 is indirect, and an index/immediate data is specified, then the immediate data is interpreted as a natural index and the pushed value is read from $[R_1 + \text{Index16}]$.

PUSHn

Syntax

`PUSHn {@}R1 {Index16|Immed16}`

Description

Adjust the stack pointer **R0**, and store a natural value on the stack.

Operation

`R0 <= R0 - sizeof (VOID *)`
`[R0] <= Operand 1`

Table 181. PUSHn Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Immediate/index absent 1 = Immediate/index present
	6	Reserved = 0
	0..5	Opcode = 0x35
1	Bit	Description
	7..4	Reserved = 0
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 1 is direct, and an index/immediate data is specified, then the immediate data is fetched as a signed value and is added to the Operand 1 register contents such that Operand 1 = $R_1 + \text{Immed16}$.
- If Operand 1 is indirect, and an index/immediate data is specified, then the immediate data is interpreted as a natural index and the Operand 1 value pushed is fetched from $[R_1 + \text{Index16}]$.

RET

Syntax

RET

Description

This instruction fetches the return address from the stack, sets the **IP** to the value, adjusts the stack pointer register **R0**, and continues execution at the return address. If the RET is a final return from the EBC driver, then execution control returns to the caller, which may be EBC or native code.

Operation

IP <= [R0]
R0 <= R0 + 16

Table 182. RET Instruction Encoding

BYTE	Description	
0	Bit	Description
	6..7	Reserved = 0
	0..5	Opcode = 0x04
1	Reserved = 0	

Behaviors and Restrictions

- An alignment exception will be generated if the return address is not aligned on a 16-bit boundary.

SHL

Syntax

SHL[32|64] {**@**}R₁, {**@**}R₂ {**Index16**|**Immed16**}

Description

Left-shifts Operand 1 by Operand 2 bit positions and stores the result back to Operand 1. The operand sizes may be either 32-bits (SHL32) or 64 bits (SHL64).

Operation

Operand 1 <= **Operand 1** << **Operand 2**

Table 183. SHL Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 2 immediate/index absent 1 = Operand 2 immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x17
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as an unsigned value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the Operand 2 register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is SHL32, and Operand 1 is direct, then the result is stored to the Operand 1 register with the upper 32 bits cleared.

SHR

Syntax

SHR[32|64] {**@**}R₁, {**@**}R₂ {**Index16|Immed16**}

Description

Right-shifts unsigned Operand 1 by Operand 2 bit positions and stores the result back to Operand 1. The operand sizes may be either 32-bits (SHR32) or 64 bits (SHR64).

Operation

Operand 1 <= **Operand 1** >> **Operand 2**

Table 184. SHR Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 2 immediate/index absent 1 = Operand 2 immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x18
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as an unsigned value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the Operand 2 register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is SHR32, and Operand 1 is direct, then the result is stored to the Operand 1 register with the upper 32 bits cleared.

STORESP

Syntax

STORESP R_1 , [IP|Flags]

Description

This instruction transfers the contents of a dedicated register to a general-purpose register. See [Table 143](#) for the VM dedicated registers and their corresponding index values.

Operation

Operand 1 \leftarrow **Operand 2**

Table 185. STORESP Instruction Encoding

BYTE	Description	
0	Bit	Description
	6..7	Reserved = 0
	0..5	Opcode = 0x2A
1	7	Reserved = 0
	4..6	Operand 2 dedicated register index
	3	Reserved = 0
	0..2	Operand 1 general purpose register

Behaviors and Restrictions

- Specifying an invalid dedicated register index results in an instruction encoding exception.

SUB

Syntax

SUB[32|64] {**@**}R₁, {**@**}R₂ {**Index16**|**Immed16**}

Description

Subtracts a 32-bit (SUB32) or 64-bit (SUB64) signed Operand 2 value from a signed Operand 1 value of the same size, and stores the result to Operand 1.

Operation

Operand 1 <= **Operand 1** - **Operand 2**

Table 186. SUB Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 2 immediate/index absent 1 = Operand 2 immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x0D
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as a signed value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the Operand 2 register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is SUB32 and Operand 1 is direct, then the result is stored to the Operand 1 register with the upper 32 bits cleared.

XOR

Syntax

XOR[32|64] {**@**}R₁, {**@**}R₂ {**Index16**|**Immed16**}

Description

Performs a bit-wise exclusive OR of two 32-bit (XOR32) or 64-bit (XOR64) operands, and stores the result back to Operand 1.

Operation

Operand 1 <= **Operand 1 XOR Operand 2**

Table 187. XOR Instruction Encoding

BYTE	Description	
0	Bit	Description
	7	0 = Operand 2 immediate/index absent 1 = Operand 2 immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x16
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as an unsigned value at address [R₂ + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the Operand 2 register contents such that Operand 2 = R₂ + Immed16.
- If the instruction is XOR32 and Operand1 is direct, then the result is stored to the Operand 1 register with the upper 32-bits cleared.

21.9 Runtime and Software Conventions

21.9.1 Calling Outside VM

Calls can be made to routines in other modules that are native or in another VM. It is the responsibility of the calling VM to prepare the outgoing arguments correctly to make the call outside the VM. It is also the responsibility of the VM to prepare the incoming arguments correctly for the call from outside the VM. Calls outside the VM must use the [CALLEX](#) instruction.

21.9.2 Calling Inside VM

Calls inside VM can be made either directly using the [CALL](#) or [CALLEX](#) instructions. Using direct CALL instructions is an optimization.

21.9.3 Parameter Passing

Parameters are pushed on the VM stack per the CDECL calling convention. Per this convention, the last argument in the parameter list is pushed on the stack first, and the first argument in the parameter list is pushed on the stack last.

All parameters are stored or accessed as natural size (using naturally sized instruction) except 64-bit integers, which are pushed as 64-bit values. 32-bit integers are pushed as natural size (since they should be passed as 64-bit parameter values on 64-bit machines).

21.9.4 Return Values

Return values of 8 bytes or less in size are returned in general-purpose register **R7**. Return values larger than 8 bytes are not supported.

21.9.5 Binary Format

PE32+ format will be used for generating binaries for the VM. A VarBss section will be included in the binary image. All global and static variables will be placed in this section. The size of the section will be based on worst-case 64-bit pointers. Initialized data and pointers will also be placed in the VarBss section, with the compiler generating code to initialize the values at runtime.

21.10 Architectural Requirements

This section provides a high level overview of the architectural requirements that are necessary to support execution of EBC on a platform.

21.10.1 EBC Image Requirements

All EBC images will be PE32+ format. Some minor additions to the format will be required to support EBC images. See the *Microsoft Portable Executable and Common Object File Format Specification* pointed to in [Appendix Q](#) for details of this image file format.

A given EBC image must be executable on different platforms, independent of whether it is a 32- or 64-bit processor. All EBC images should be driver implementations.

21.10.2 EBC Execution Interfacing Requirements

EBC drivers will typically be designed to execute in an (usually preboot) EFI environment. As such, EBC drivers must be able to invoke protocols and expose protocols for use by other drivers or applications. The following execution transitions must be supported:

- EBC calling EBC
- EBC calling native code
- Native code calling EBC
- Native code calling native code
- Returning from all the above transitions

Obviously native code calling native code is available by default, so is not discussed in this document.

To maintain backward compatibility with existing native code, and minimize the overhead for non-EBC drivers calling EBC protocols, all four transitions must be seamless from the application perspective. Therefore, drivers, whether EBC or native, shall not be required to have any knowledge of whether or not the calling code, or the code being called, is native or EBC compiled code. The onus is put on the tools and interpreter to support this requirement.

21.10.3 Interfacing Function Parameters Requirements

To allow code execution across protocol boundaries, the interpreter must ensure that parameters passed across execution transitions are handled in the same manner as the standard parameter passing convention for the native processor.

21.10.4 Function Return Requirements

The interpreter must support standard function returns to resume execution to the caller of external protocols. The details of this requirement are specific to the native processor. The called function must not be required to have any knowledge of whether or not the caller is EBC or native code.

21.10.5 Function Return Values Requirements

The interpreter must support standard function return values from called protocols. The exact implementation of this functionality is dependent on the native processor. This requirement applies to return values of 64 bits or less. The called function must not be required to have any knowledge of whether or not the caller is EBC or native code. Note that returning of structures is not supported.

21.11 EBC Interpreter Protocol

The EFI EBC protocol provides services to execute EBC images, which will typically be loaded into option ROMs.

EFI_EBC_PROTOCOL

Summary

This protocol provides the services that allow execution of EBC images.

GUID

```
#define EFI_EBC_PROTOCOL_GUID \
    {0x13ac6dd1,0x73d0,0x11d4, \
     {0xb0,0x6b,0x00,0xaa,0x00,0xbd,0x6d,0xe7}}
```

Protocol Interface Structure

```
typedef struct _EFI_EBC_PROTOCOL {
    EFI_EBC_CREATE_THUNK           CreateThunk;
    EFI_EBC_UNLOAD_IMAGE           UnloadImage;
    EFI_EBC_REGISTER_ICACHE_FLUSH RegisterICacheFlush;
    EFI_EBC_GET_VERSION            GetVersion;
} EFI_EBC_PROTOCOL;
```

Parameters

<i>CreateThunk</i>	Creates a thunk for an EBC image entry point or protocol service, and returns a pointer to the thunk. See the CreateThunk () function description.
<i>UnloadImage</i>	Called when an EBC image is unloaded to allow the interpreter to perform any cleanup associated with the image's execution. See the UnloadImage () function description.
<i>RegisterICacheFlush</i>	Called to register a callback function that the EBC interpreter can call to flush the processor instruction cache after creating thunks. See the RegisterICacheFlush () function description.
<i>GetVersion</i>	Called to get the version of the associated EBC interpreter. See the GetVersion () function description.

Description

The EFI EBC protocol provides services to load and execute EBC images, which will typically be loaded into option ROMs. The image loader will load the EBC image, perform standard relocations, and invoke the [CreateThunk \(\)](#) service to create a thunk for the EBC image's entry point. The image can then be run using the standard EFI start image services.

EFI_EBC_PROTOCOL.CreateThunk()

Summary

Creates a thunk for an EBC entry point, returning the address of the thunk.

Prototype

```
typedef
EFI_STATUS
(EFI_API *EFI_EBC_CREATE_THUNK) (
    IN  EFI_EBC_PROTOCOL      *This,
    IN  EFI_HANDLE            ImageHandle,
    IN  VOID                  *EbcEntryPoint,
    OUT VOID                  **Thunk
);
```

Parameters

<i>This</i>	A pointer to the EFI EBC PROTOCOL instance. This protocol is defined in Section 21.11 .
<i>ImageHandle</i>	Handle of image for which the thunk is being created.
<i>EbcEntryPoint</i>	Address of the actual EBC entry point or protocol service the thunk should call.
<i>Thunk</i>	Returned pointer to a thunk created.

Description

A PE32+ EBC image, like any other PE32+ image, contains an optional header that specifies the entry point for image execution. However for EBC images this is the entry point of EBC instructions, so is not directly executable by the native processor. Therefore when an EBC image is loaded, the loader must call this service to get a pointer to native code (thunk) that can be executed which will invoke the interpreter to begin execution at the original EBC entry point.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_INVALID_PARAMETER	Image entry point is not 2-byte aligned.
EFI_OUT_OF_RESOURCES	Memory could not be allocated for the thunk.

EFI_EBC_PROTOCOL.UnloadImage()

Summary

Called prior to unloading an EBC image from memory.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EBC_UNLOAD_IMAGE) (
    IN EFI_EBC_PROTOCOL      *This,
    IN EFI_HANDLE            ImageHandle
);
```

Parameters

<i>This</i>	A pointer to the EFI_EBC_PROTOCOL instance. This protocol is defined in Section 21.11 .
<i>ImageHandle</i>	Image handle of the EBC image that is being unloaded from memory.

Description

This function is called after an EBC image has exited, but before the image is actually unloaded. It is intended to provide the interpreter with the opportunity to perform any cleanup that may be necessary as a result of loading and executing the image.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_INVALID_PARAMETER	Image handle is not recognized as belonging to an EBC image that has been executed.

EFI_EBC_PROTOCOL.RegisterICacheFlush()

Summary

Registers a callback function that the EBC interpreter calls to flush the processor instruction cache following creation of thunks.

Prototype

```
typedef
EFI_STATUS
(* EFI_EBC_REGISTER_ICACHE_FLUSH) (
    IN EFI_EBC_PROTOCOL           *This,
    IN EBC_ICACHE_FLUSH          Flush
);
```

Parameters

<i>This</i>	A pointer to the EFI_EBC_PROTOCOL instance. This protocol is defined in Section 21.11 .
<i>Flush</i>	Pointer to a function of type EBC_ICACHE_FLUSH . See “Related Definitions” below for a detailed description of this type.

Related Definitions

```
typedef
EFI_STATUS
(* EBC_ICACHE_FLUSH) (
    IN EFI_PHYSICAL_ADDRESS      Start,
    IN UINT64                    Length
);
```

<i>Start</i>	The beginning physical address to flush from the processor’s instruction cache.
--------------	---

<i>Length</i>	The number of bytes to flush from the processor’s instruction cache.
---------------	--

This is the prototype for the *Flush* callback routine. A pointer to a routine of this type is passed to the EBC [EFI_EBC_REGISTER_ICACHE_FLUSH](#) protocol service.

Description

An EBC image’s original PE32+ entry point is not directly executable by the native processor. Therefore to execute an EBC image, a thunk (which invokes the EBC interpreter for the image’s original entry point) must be created for the entry point, and the thunk is executed when the EBC image is started. Since the thunks may be created on-the-fly in memory, the processor’s instruction cache may require to be flushed after thunks are created. The caller to this EBC service can provide a pointer to a function to flush the instruction cache for any thunks created after the [CreateThunk\(\)](#) service has been called. If an instruction-cache flush callback is not provided to the interpreter, then the interpreter assumes the system has no instruction cache, or that flushing the cache is not required following creation of thunks.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
-------------	--------------------------------------

EFI_EBC_PROTOCOL.GetVersion()

Summary

Called to get the version of the interpreter.

Prototype

```

typedef
EFI_STATUS
(* EFI_EBC_GET_VERSION) (
    IN EFI_EBC_PROTOCOL      *This,
    OUT UINT64                *Version
);

```

Parameters

This A pointer to the [EFI_EBC_PROTOCOL](#) instance. This protocol is defined in [Section 21.11](#).

Version Pointer to where to store the returned version of the interpreter.

Description

This function is called to get the version of the loaded EBC interpreter. The value and format of the returned version is identical to that returned by the EBC [BREAK](#) 1 instruction.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_INVALID_PARAMETER	Version pointer is NULL .

21.12 EBC Tools

21.12.1 EBC C Compiler

This section describes the responsibilities of the EBC C compiler. To fully specify these responsibilities requires that the thinking mechanisms between EBC and native code be described.

21.12.2 C Coding Convention

The EBC C compiler supports only the C programming language. There is no support for C++, inline assembly, floating point types/operations, or C calling conventions other than CDECL.

Pointer type in C is supported only as 64-bit pointer. The code should be 64-bit pointer ready (not assign pointers to integers and vice versa).

The compiler does not support user-defined sections through pragmas.

Global variables containing pointers that are initialized will be put in the uninitialized VarBss section and the compiler will generate code to initialize these variables during load time. The code

will be placed in an init text section. This compiler-generated code will be executed before the actual image entry point is executed.

21.12.3 EBC Interface Assembly Instructions

The EBC instruction set includes two forms of a [CALL](#) instruction that can be used to invoke external protocols. Their assembly language formats are:

```
CALLEX Immed64
CALLEX32 {@}R1 {Immed32}
```

Both forms can be used to invoke external protocols at an absolute address specified by the immediate data and/or register operand. The second form also supports jumping to code at a relative address. When one of these instructions is executed, the interpreter is responsible for thunking arguments and then jumping to the destination address. When the called function returns, code begins execution at the EBC instruction following the CALL instruction. The process by which this happens is called thunking. Later sections describe this operation in detail.

21.12.4 Stack Maintenance and Argument Passing

There are several EBC assembly instructions that directly manipulate the stack contents and stack pointer. These instructions operate on the EBC stack, not the interpreter stack. The instructions include the EBC [PUSH](#), [POP](#), [PUSHn](#), and [POPn](#), and all forms of the [MOV](#) instructions.

These instructions must adjust the EBC stack pointer in the same manner as equivalent instructions of the native instruction set. With this implementation, parameters pushed on the stack by an EBC driver can be accessed normally for stack-based native code. If native code expects parameters in registers, then the interpreter thunking process must transfer the arguments from EBC stack to the appropriate processor registers. The process would need to be reversed when native code calls EBC.

21.12.5 Native to EBC Arguments Calling Convention

The calling convention for arguments passed to EBC functions follows the standard CDECL calling convention. The arguments must be pushed as their native size. After the function arguments have been pushed on the stack, execution is passed to the called EBC function. The overhead of thunking the function parameters depends on the standard parameter passing convention for the host processor. The implementation of this functionality is left to the interpreter.

21.12.6 EBC to Native Arguments Calling Convention

When EBC makes function calls via function pointers, the EBC C compiler cannot determine whether the calls are to native code or EBC. It therefore assumes that the calls are to native code, and emits the appropriate EBC [CALLEX](#) instructions. To be compatible with calls to native code, the calling convention of EBC calling native code must follow the parameter passing convention of the native processor. The EBC C compiler generates EBC instructions that push all arguments on the stack. The interpreter is then responsible for performing the necessary thunking. The exact implementation of this functionality is left to the interpreter.

21.12.7 EBC to EBC Arguments Calling Convention

If the EBC C compiler is able to determine that a function call is to a local function, it can emit a standard EBC [CALL](#) instruction. In this case, the function arguments are passed as described in the other sections of this specification.

21.12.8 Function Returns

When EBC calls an external function, the thinking process includes setting up the host processor stack or registers such that when the called function returns, execution is passed back to the EBC at the instruction following the call. The implementation is left to the interpreter, but it must follow the standard function return process of the host processor. Typically this will require the interpreter to push the return address on the stack or move it to a processor register prior to calling the external function.

21.12.9 Function Return Values

EBC function return values of 8 bytes or less are returned in VM general-purpose register **R7**. Returning values larger than 8 bytes on the stack is not supported. Instead, the caller or callee must allocate memory for the return value, and the caller can pass a pointer to the callee, or the callee can return a pointer to the value in the standard return register **R7**.

If an EBC function returns to native code, then the interpreter thinking process is responsible for transferring the contents of **R7** to an appropriate location such that the caller has access to the value using standard native code. Typically the value will be transferred to a processor register. Conversely, if a native function returns to an EBC function, the interpreter is responsible for transferring the return value from the native return memory or register location into VM register **R7**.

21.12.10 Thinking

Thinking is the process by which transitions between execution of native and EBC are handled. The major issues that must be addressed for thinking are the handling of function arguments, how the external function is invoked, and how return values and function returns are handled. The following sections describe the thinking process for the possible transitions.

21.12.10.1 Thinking EBC to Native Code

By definition, all external calls from within EBC are calls to native code. The EBC [CALLEX](#) instructions are used to make these calls. A typical application for EBC calling native code would be a simple “Hello World” driver. For a UEFI driver, the code could be written as shown below.

```

EFI_STATUS EfiMain (
    IN EFI_HANDLE          ImageHandle,
    IN EFI_SYSTEM_TABLE   *ST
)
{
    ST->ConOut->OutputString(ST->ConOut, L"Hello World!");
    return EFI_SUCCESS;
}

```

This C code, when compiled to EBC assembly, could result in two [PUSHn](#) instructions to push the parameters on the stack, some code to get the absolute address of the [OutputString\(\)](#) function, then a CALLEX instruction to jump to native code. Typical pseudo assembly code for the function call could be something like the following:

```
PUSHn    _HelloString
PUSHn    _ConOut
MOVnw    R1, _OutputString
CALLEX64R1
```

The interpreter is responsible for executing the PUSHn instructions to push the arguments on the EBC stack when interpreting the PUSHn instructions. When the CALLEX instruction is encountered, it must think to external native code. The exact thinking mechanism is native processor dependent. For example, a supported 32-bit thinking implementation could simply move the system stack pointer to point to the EBC stack, then perform a [CALL](#) to the absolute address specified in VM register **R1**. However, the function calling convention for the Itanium processor family calls for the first 8 function arguments being passed in registers. Therefore, the Itanium processor family thinking mechanism requires the arguments to be copied from the EBC stack into processor registers. Then a CALL can be performed to jump to the absolute address in VM register **R1**. Note that since the interpreter is not aware of the number of arguments to the function being called, the maximum amount of data may be copied from the EBC stack into processor registers.

21.12.10.2 Thunking Native Code to EBC

An EBC driver may install protocols for use by other EBC drivers, or UEFI drivers or applications. These protocols provide the mechanism by which external native code can call EBC. Typical C code to install a generic protocol is shown below.

```
EFI_STATUS Foo(UINT32 Arg1, UINT32 Arg2);

MyProtInterface->Service1= Foo;

Status = LibInstallProtocolInterfaces (&Handle, &MyProtGUID,
MyProtInterface, NULL);
```

To support thunking native code to EBC, the EBC compiler resolves all EBC function pointers using one level of indirection. In this way, the address of an EBC function actually becomes the address of a piece of native (thunk) code that invokes the interpreter to execute the actual EBC function. As a result of this implementation, any time the address of an EBC function is taken, the EBC C compiler must generate the following:

- A 64-bit function pointer data object that contains the actual address of the EBC function
- EBC initialization code that is executed before the image entry point that will execute EBC [BREAK](#) 5 instructions to create thunks for each function pointer data object
- Associated relocations for the above

So for the above code sample, the compiler must generate EBC initialization code similar to the following. This code is executed prior to execution of the actual EBC driver's entry point.

```
MOVqq R7, Foo_pointer; get address of Foo pointer
```

```
BREAK 5 ; create a thunk for the function
```

The BREAK instruction causes the interpreter to create native thunk code elsewhere in memory, and then modify the memory location pointed to by R7 to point to the newly created thunk code for EBC function Foo. From within EBC, when the address of Foo is taken, the address of the thunk is actually returned. So for the assignment of the protocol Service1 above, the EBC C compiler will generate something like the following:

```
MOVqq R7, Foo_pointer; get address of Foo function pointer
MOVqq R7, @R7 ; one level of indirection
MOVn R6, _MyProtInterface->Service1 ; get address of variable
MOVqq @R6, R7 ; address of thunk to ->Service1
```

21.12.10.3 Thunking EBC to EBC

EBC can call EBC via function pointers or protocols. These two mechanisms are treated identically by the EBC C compiler, and are performed using EBC [CALLEX](#) instructions. For EBC to call EBC, the EBC being called must have provided the address of the function. As described above, the address is actually the address of native thunk code for the actual EBC function. Therefore, when EBC calls EBC, the interpreter assumes native code is being called so prepares function arguments accordingly, and then makes the call. The native thunk code assumes native code is calling EBC, so will basically “undo” the preparation of function arguments, and then invoke the interpreter to execute the actual EBC function of interest.

21.12.11 EBC Linker

New constants must be defined for use by the linker in processing EBC images. For EBC images, the linker must set the machine type in the PE file header accordingly to indicate that the image contains EBC.

```
#define IMAGE_FILE_MACHINE_EBC 0x0EBC
```

In addition, the linker must support EBC images with of the following subsystem types as set in a PE32+ optional header:

```
#define IMAGE_SUBSYSTEM_EFI_APPLICATION 10
#define IMAGE_SUBSYSTEM_EFI_BOOT_SERVICE_DRIVER 11
#define IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER 12
```

For EFI EBC images and object files, the following relocation types must be supported:

```
// No relocations required
#define IMAGE_REL_EBC_ABSOLUTE 0x0000
// 32-bit address w/o image base
#define IMAGE_REL_EBC_ADDR32NB 0x0001
// 32-bit relative address from byte following relocs
#define IMAGE_REL_EBC_REL32 0x0002
// Section table index
#define IMAGE_REL_EBC_SECTION 0x0003
// Offset within section
#define IMAGE_REL_EBC_SECREL 0x0004
```

The ADDR32NB relocation is used internally to the linker when RVAs are emitted. It also is used for version resources which probably will not be used. The REL32 relocation is for PC relative addressing on code. The SECTION and SECREL relocations are used for debug information.

21.12.12 Image Loader

The EFI image loader is responsible for loading an executable image into memory and applying relocation information so that an image can execute at the address in memory where it has been loaded prior to execution of the image. For EBC images, the image loader must also invoke the interpreter protocol to create a thunk for the image entry point and return the address of this thunk. After loading the image in this manner, the image can be executed in the standard manner. To implement this functionality, only minor changes will be made to EFI service [EFI_BOOT_SERVICES.LoadImage\(\)](#), and no changes should be made to [EFI_BOOT_SERVICES.StartImage\(\)](#).

After the image is unloaded, the EFI image load service must call the EBC [EFI_BOOT_SERVICES.UnloadImage\(\)](#) service to perform any cleanup to complete unloading of the image. Typically this will include freeing up any memory allocated for thunks for the image during load and execution.

21.12.13 Debug Support

The interpreter must support debugging in an EFI environment per the EFI debug support protocol.

21.13 VM Exception Handling

This section lists the different types of exceptions that the VM may assert during execution of an EBC image. If a debugger is attached to the EBC driver via the EFI debug support protocol, then the debugger should be able to capture and identify the exception type. If a debugger is not attached, then depending on the severity of the exception, the interpreter may do one of the following:

- Invoke the EFI ASSERT() macro, which will typically display an error message and halt the system
- Sit in a while(1) loop to hang the system
- Ignore the exception and continue execution of the image (minor exceptions only)

It is a platform policy decision as to the action taken in response to EBC exceptions. The following sections describe the exceptions that may be generated by the VM.

21.13.1 Divide By 0 Exception

A divide-by-0 exception can occur for the EBC instructions [DIV](#), [DIVU](#), [MOD](#), and [MODU](#).

21.13.2 Debug Break Exception

A debug break exception occurs if the VM encounters a [BREAK](#) instruction with a break code of 3.

21.13.3 Invalid Opcode Exception

An invalid opcode exception will occur if the interpreter encounters a reserved opcode during execution.

21.13.4 Stack Fault Exception

A stack fault exception can occur if the interpreter detects that function nesting within the interpreter or system interrupts was sufficient to potentially corrupt the EBC image's stack contents. This exception could also occur if the EBC driver attempts to adjust the stack pointer outside the range allocated to the driver.

21.13.5 Alignment Exception

An alignment exception can occur if the particular implementation of the interpreter does not support unaligned accesses to data or code. It may also occur if the stack pointer or instruction pointer becomes misaligned.

21.13.6 Instruction Encoding Exception

An instruction encoding exception can occur for the following:

- For some instructions, if an Operand 1 index is specified and Operand 1 is direct
- If an instruction encoding has reserved bits set to values other than 0
- If an instruction encoding has a field set to a reserved value.

21.13.7 Bad Break Exception

A bad break exception occurs if the VM encounters a [BREAK](#) instruction with a break code of 0, or any other unrecognized or unsupported break code.

21.13.8 Undefined Exception

An undefined exception can occur for other conditions detected by the VM. The cause of such an exception is dependent on the VM implementation, but will most likely include internal VM faults.

21.14 Option ROM Formats

The new option ROM capability is designed to be a departure from the legacy method of formatting an option ROM. PCI local bus add-in cards are the primary targets for this design although support for future bus types will be added as necessary. EFI EBC drivers can be stored in option ROMs or on hard drives in an EFI system partition.

The new format defined for the UEFI specification is intended to coexist with legacy format PCI Expansion ROM images. This provides the ability for IHVs to make a single option ROM binary that contains both legacy and new format images at the same time. This is important for the ability to have single add-in card SKUs that can work in a variety of systems both with and without native support for UEFI. Support for multiple image types in this way provides a smooth migration path

during the period before widespread adoption of UEFI drivers as the primary means of support for software needed to accomplish add-in card operation in the pre-OS boot timeframe.

21.14.1 EFI Drivers for PCI Add-in Cards

The location mechanism for UEFI drivers in PCI option ROM containers is described fully in [Section 10.3](#). Readers should refer to this section for complete details of the scheme and associated data structures.

21.14.2 Non-PCI Bus Support

EFI expansion ROMs are not supported on any other bus besides PCI local bus in the current revision of the UEFI specification.

This means that support for UEFI drivers in legacy ISA add-in card ROMs is explicitly excluded.

Support for UEFI drivers to be located on add-in card type devices for future bus designs other than PCI local bus will be added to future revisions of the UEFI specification. This support will depend upon the specifications that govern such new bus designs with respect to the mechanisms defined for support of driver code on devices.

Firmware Update and Reporting

The UEFI Firmware Management Protocol provides an abstraction for device to provide firmware management support. The base requirements for managing device firmware images include identifying firmware image revision level and programming the image into the device.

The protocol for managing firmware provides the following services.

- Get the attributes of the current firmware image. Attributes include revision level.
- Get a copy of the current firmware image. As an example, this service could be used by a management application to facilitate a firmware roll-back.
- Program the device with a firmware image supplied by the user.
- Label all the firmware images within a device with a single version.

When UEFI Firmware Management Protocol (FMP) instance is intended to perform the update of an option ROM loaded from a PCI or PCI Express device, it is recommended that the FMP instance be attached to the handle with **EFI_LOADED_IMAGE_PROTOCOL** for said Option ROM.

When the FMP instance is intended to update internal device firmware, or a combination of device firmware and Option ROM, the FMP instance may instead be attached to the Controller handle of the device. However in the case where multiple devices represented by multiple controller handles are served by the same firmware store, only a single Controller handle should expose FMP. In all cases a specific updatable hardware firmware store must be represented by exactly one FMP instance.

Care should be taken to ensure that the FMP instance reports current version data that accurately represents the actual contents of the firmware store of the device exposing FMP, because in some cases the device driver currently operating the device may have been loaded from another device or media.

22.1 Firmware Management Protocol

EFI_FIRMWARE_MANAGEMENT_PROTOCOL

Summary

Firmware Management application invokes this protocol to manage device firmware.

GUID

```
// {86C77A67-0B97-4633-A187-49104D0685C7}
#define EFI_FIRMWARE_MANAGEMENT_PROTOCOL_GUID \
    { 0x86c77a67, 0xb97, 0x4633, \
      {0xa1, 0x87, 0x49, 0x10, 0x4d, 0x06, 0x85, 0xc7 }}
```

Protocol

```
typedef struct _EFI_FIRMWARE_MANAGEMENT_PROTOCOL {
    EFI_FIRMWARE_MANAGEMENT_PROTOCOL_GET_IMAGE_INFO  GetImageInfo;
    EFI_FIRMWARE_MANAGEMENT_PROTOCOL_GET_IMAGE      GetImage;
    EFI_FIRMWARE_MANAGEMENT_PROTOCOL_SET_IMAGE      SetImage;
    EFI_FIRMWARE_MANAGEMENT_PROTOCOL_CHECK_IMAGE    CheckImage;

```

Members

GetImageInfo

Returns information about the current firmware image(s) of the device.

GetImage

Retrieves a copy of the current firmware image of the device.

SetImage

Updates the device firmware image of the device.

CheckImage

Checks if the firmware image is valid for the device.

GetPackageInfo

Returns information about the current firmware package.

SetPackageInfo

Updates information about the firmware package.

EFI_FIRMWARE_MANAGEMENT_PROTOCOL.GetImageInfo()

Summary

Returns information about the current firmware image(s) of the device.

Protocol

```
typedef
EFI_STATUS
(EFIAPI *EFI_FIRMWARE_MANAGEMENT_PROTOCOL_GET_IMAGE_INFO) (
    IN EFI_FIRMWARE_MANAGEMENT_PROTOCOL      *This,
    IN OUT  UINTN                             *ImageInfoSize,
    IN OUT  EFI_FIRMWARE_IMAGE_DESCRIPTOR    *ImageInfo,
    OUT     UINT32                             *DescriptorVersion
    OUT     UINT8                             *DescriptorCount,
    OUT     UINTN                             *DescriptorSize,
    OUT     UINT32                             *PackageVersion,
    OUT     CHAR16                             **PackageVersionName
) ;
```

Parameters

This

A pointer to the **EFI_FIRMWARE_MANAGEMENT_PROTOCOL** instance.

ImageInfoSize

A pointer to the size, in bytes, of the *ImageInfo* buffer. On input, this is the size of the buffer allocated by the caller. On output, it is the size of the buffer returned by the firmware if the buffer was large enough, or the size of the buffer needed to contain the image(s) information if the buffer was too small.

ImageInfo

A pointer to the buffer in which firmware places the current image(s) information. The information is an array of **EFI_FIRMWARE_IMAGE_DESCRIPTOR**s. See “Related Definitions”.

DescriptorVersion

A pointer to the location in which firmware returns the version number associated with the **EFI_FIRMWARE_IMAGE_DESCRIPTOR**. See “Related Definitions”.

DescriptorCount

A pointer to the location in which firmware returns the number of descriptors or firmware images within this device.

DescriptorSize

A pointer to the location in which firmware returns the size, in bytes, of an individual **EFI_FIRMWARE_IMAGE_DESCRIPTOR**.

PackageVersion

A version number that represents all the firmware images in the device. The format is vendor specific and new version must have a greater value than the old version. If *PackageVersion* is not supported, the value is 0xFFFFFFFF. A value of 0xFFFFFFFFE indicates that package version comparison is to be performed using *PackageVersionName*. A value of 0xFFFFFFFFD indicates that package version update is in progress.

PackageVersionName

A pointer to a pointer to a null-terminated string representing the package version name. The buffer is allocated by this function with **AllocatePool()**, and it is the caller's responsibility to free it with a call to **FreePool()**.

Related Definitions

```

//*****
// EFI_FIRMWARE_IMAGE_DESCRIPTOR
//*****
typedef struct {
    UINT8           ImageIndex;
    EFI_GUID        ImageTypeId;
    UINT64          ImageId;
    CHAR16          *ImageIdName;
    UINT32          Version;
    CHAR16          *VersionName;
    UINTN           Size;
    UINT64          AttributesSupported;
    UINT64          AttributesSetting;
    UINT64          Compatibilities;
    UINT32          LowestSupportedImageVersion; \
//Introduced with DescriptorVersion 2+
    UINT32          LastAttemptVersion; //Introduced with V3+
    UINT32          LastAttemptStatus; //Introduced with V3+
    UINT64          HardwareInstance; //Introduced with V3+
} EFI_FIRMWARE_IMAGE_DESCRIPTOR;

```

ImageIndex

A unique number identifying the firmware image within the device. The number is between 1 and *DescriptorCount*.

ImageTypeId

A unique GUID identifying the firmware image type.

ImageId

A unique number identifying the firmware image.

ImageIdName

A pointer to a null-terminated string representing the firmware image name.

Version

Identifies the version of the device firmware. The format is vendor specific and new version must have a greater value than an old version.

VersionName

A pointer to a null-terminated string representing the firmware image version name.

Size

Size of the image in bytes. If size=0, then only *ImageIndex* and *ImageTypeId* are valid.

AttributesSupported

Image attributes that are supported by this device. See “Image Attribute Definitions” for possible returned values of this parameter. A value of 1 indicates the attribute is supported and the current setting value is indicated in *AttributesSetting*. A value of 0 indicates the attribute is not supported and the current setting value in *AttributesSetting* is meaningless.

AttributesSetting

Image attributes. See “Image Attribute Definitions” for possible returned values of this parameter.

Compatibilities

Image compatibilities. See “Image Compatibility Definitions” for possible returned values of this parameter.

LowestSupportedImageVersion

Describes the lowest *ImageDescriptor* version that the device will accept. Only present in version 2 or higher.

LastAttemptVersion

Describes the version that was last attempted to update. If no update attempted the value will be 0. If the update attempted was improperly formatted and no version number was available then the value will be zero. Only present in version 3 or higher.

LastAttemptStatus

Describes the status that was last attempted to update. If no update has been attempted the value will be **LAST_ATTEMPT_STATUS_SUCCESS**. See "Related Definitions" in [Section 22.3](#) for Last Attempt Status values. Only present in version 3 or higher.

HardwareInstance

An optional number to identify the unique hardware instance within the system for devices that may have multiple instances (Example: a plug in pci network card). This number must be unique within the namespace of the *ImageTypeId* GUID and *ImageIndex*. For FMP instances that have multiple descriptors for a single hardware instance, all descriptors must have the same *HardwareInstance* value. This number must be consistent between boots and should be based on some sort of hardware identified unique id (serial number, etc) whenever possible. If a hardware based number is not available the FMP provider may use some other characteristic such as device path, bus/dev/function, slot num, etc for generating the

HardwareInstance. For implementations that will never have more than one instance a zero can be used. A zero means the FMP provider is not able to determine a unique hardware instance number or a hardware instance number is not needed. Only present in version 3 or higher.

```

//*****
// Image Attribute Definitions
//*****
#define IMAGE_ATTRIBUTE_IMAGE_UPDATABLE 0x0000000000000001
#define IMAGE_ATTRIBUTE_RESET_REQUIRED 0x0000000000000002
#define IMAGE_ATTRIBUTE_AUTHENTICATION_REQUIRED
0x0000000000000004
#define IMAGE_ATTRIBUTE_IN_USE 0x0000000000000008
#define IMAGE_ATTRIBUTE_UEFI_IMAGE 0x0000000000000010

```

The attribute **IMAGE_ATTRIBUTE_IMAGE_UPDATABLE** indicates this device supports firmware image update.

The attribute **IMAGE_ATTRIBUTE_RESET_REQUIRED** indicates a reset of the device is required for the new firmware image to take effect after a firmware update. The device is the device hosting the firmware image.

The attribute **IMAGE_ATTRIBUTE_AUTHENTICATION_REQUIRED** indicates authentication is required to perform the following image operations: **GetImage()**, **SetImage()**, and **CheckImage()**. See “Image Attribute – Authentication”.

The attribute **IMAGE_ATTRIBUTE_IN_USE** indicates the current state of the firmware image. This distinguishes firmware images in a device that supports redundant images.

The attribute **IMAGE_ATTRIBUTE_UEFI_IMAGE** indicates that this image is an EFI compatible image.

```

//*****
// Image Compatibility Definitions
//*****
#define IMAGE_COMPATIBILITY_CHECK_SUPPORTED 0x0000000000000001

```

Values from 0x0000000000000002 thru 0x000000000000FFFF are reserved for future assignments.

Values from 0x0000000000010000 thru 0xFFFFFFFFFFFFFFFF are used by firmware vendor for compatibility check.

```

//*****
// Descriptor Version exposed by GetImageInfo() function
//*****
#define EFI_FIRMWARE_IMAGE_DESCRIPTOR_VERSION 3

//*****
// Image Attribute - Authentication Required
//*****
typedef struct {
    UINT64                               MonotonicCount;
    WIN_CERTIFICATE_UEFI_GUID             AuthInfo;
} EFI_FIRMWARE_IMAGE_AUTHENTICATION;

```

MonotonicCount

It is included in the signature of *AuthInfo*. It is used to ensure freshness/no replay. It is incremented during each firmware image operation.

AuthInfo

Provides the authorization for the firmware image operations. It is a signature across the image data and the Monotonic Count value. Caller uses the private key that is associated with a public key that has been provisioned via the key exchange. Because this is defined as a signature, **WIN_CERTIFICATE_UEFI_GUID**.*CertType* must be **EFI_CERT_TYPE_PKCS7_GUID**.

Description

GetImageInfo() is the only required function. **GetImage()**, **SetImage()**, **CheckImage()**, **GetPackageInfo()**, and **SetPackageInfo()** shall return **EFI_UNSUPPORTED** if not supported by the driver.

A package can have one to many firmware images. The firmware images can have the same version naming or different version naming. *PackageVersion* may be used as the representative version for all the firmware images. *PackageVersion* can be obtained from **GetPackageInfo()**. *PackageVersion* is also available in **GetImageInfo()** as **GetPackageInfo()** is optional. It also ensures the package version is in sync with the versions of the images within the package by returning the package version and image version(s) in a single function call.

The value of *ImageTypeID* is implementation specific. This feature facilitates vendor to target a single firmware release to cover multiple products within a product family. As an example, a vendor has an initial product A and then later developed a product B that is of the same product family. Product A and product B will have the same *ImageTypeID* to indicate firmware compatibility between the two products.

To determine image attributes, software must use both *AttributesSupported* and *AttributesSetting*. An attribute setting in *AttributesSetting* is meaningless if the corresponding attribute is not supported in *AttributesSupported*.

Compatibilities are used to ensure the targeted firmware image supports the current hardware configuration. *Compatibilities* are set based on the current hardware configuration and firmware

update policy should match the current settings to those supported by the new firmware image, and only permits update to proceed if the new firmware image settings are equal or greater than the current hardware configuration settings. For example, if this function returns *Compatibilities*= 0x0000000000070001 and the new firmware image supports settings=0x0000000000030001, then the update policy should block the firmware update and notify the user that updating the hardware with the new firmware image may render the hardware inoperable. This situation usually occurs when updating the hardware with an older version of firmware.

The authentication support leverages the authentication scheme employed in variable authentication. Please reference **EFI_VARIABLE_AUTHENTICATION** in the “Variable Services” section of “Services – Runtime Services” chapter.

If **IMAGE_ATTRIBUTE_AUTHENTICATION_REQUIRED** is supported and clear, then authentication is not required to perform the firmware image operations. In firmware image operations, the image pointer points to the start of the firmware image and the image size is the firmware image.

Figure 62. Firmware Image with no Authentication Support

If **IMAGE_ATTRIBUTE_AUTHENTICATION_REQUIRED** is supported and set, then authentication is required to perform the firmware image operations. In firmware image operations, the image pointer points to the start of the **authentication data** and the image size is the size of the **authentication data** and the size of the firmware image.

Figure 63. Firmware Image with Authentication Support

Status Codes Returned

EFI_SUCCESS	The image information was successfully returned.
-------------	--

EFI_BUFFER_TOO_SMALL	The <i>ImageInfo</i> buffer was too small. The current buffer size needed to hold the image(s) information is returned in <i>ImageInfoSize</i> .
EFI_INVALID_PARAMETER	<i>ImageInfoSize</i> is NULL.
EFI_DEVICE_ERROR	Valid information could not be returned. Possible corrupted image.

EFI_FIRMWARE_MANAGEMENT_PROTOCOL.GetImage()

Summary

Retrieves a copy of the current firmware image of the device.

Protocol

```

typedef
EFI_STATUS
(EFIAPI *EFI_FIRMWARE_MANAGEMENT_PROTOCOL_GET_IMAGE) (
    IN  EFI_FIRMWARE_MANAGEMENT_PROTOCOL  *This,
    IN  UINT8                               ImageIndex,
    IN  OUT VOID                            *Image,
    IN  OUT UINTN                           *ImageSize
) ;

```

Parameters

This

A pointer to the **EFI_FIRMWARE_MANAGEMENT_PROTOCOL** instance.

ImageIndex

A unique number identifying the firmware image(s) within the device. The number is between 1 and *DescriptorCount*.

Image

Points to the buffer where the current image is copied to.

ImageSize

On entry, points to the size of the buffer pointed to by *Image*, in bytes. On return, points to the length of the image, in bytes.

Related Definitions

None

Description

This function allows a copy of the current firmware image to be created and saved. The saved copy could later be used, for example, in firmware image recovery or rollback.

Status Codes Returned

EFI_SUCCESS	The current image was successfully copied to the buffer.
EFI_BUFFER_TOO_SMALL	The buffer specified by <i>ImageSize</i> is too small to hold the image. The current buffer size needed to hold the image is returned in <i>ImageSize</i> .
EFI_INVALID_PARAMETER	The <i>Image</i> was NULL.
EFI_NOT_FOUND	The current image is not copied to the buffer.
EFI_UNSUPPORTED	The operation is not supported.
EFI_SECURITY_VIOLATION	The operation could not be performed due to an authentication failure.

EFI_FIRMWARE_MANAGEMENT_PROTOCOL.SetImage()

Summary

Updates the firmware image of the device.

Protocol

```

typedef
EFI_STATUS
(EFIAPI *EFI_FIRMWARE_MANAGEMENT_PROTOCOL_SET_IMAGE) (
    IN  EFI_FIRMWARE_MANAGEMENT_PROTOCOL      *This,
    IN  UINT8                                 ImageIndex,
    IN  CONST VOID                            *Image,
    IN  UINTN                                 ImageSize,
    IN  CONST VOID                            *VendorCode,
    IN  EFI_FIRMWARE_MANAGEMENT_UPDATE_IMAGE_PROGRESS Progress,
    OUT CHAR16                                **AbortReason
) ;

```

Parameters

This

A pointer to the `EFI_FIRMWARE_MANAGEMENT_PROTOCOL` instance.

ImageIndex

A unique number identifying the firmware image(s) within the device. The number is between 1 and *DescriptorCount*.

Image

Points to the new image.

ImageSize

Size of the new image in bytes.

VendorCode

This enables vendor to implement vendor-specific firmware image update policy. Null indicates the caller did not specify the policy or use the default policy.

Progress

A function used by the driver to report the progress of the firmware update.

AbortReason

A pointer to a pointer to a null-terminated string providing more details for the aborted operation. The buffer is allocated by this function with `AllocatePool()`, and it is the caller's responsibility to free it with a call to `FreePool()`.

Related Definitions

```
typedef
EFI_STATUS
(EFI_API *EFI_FIRMWARE_MANAGEMENT_UPDATE_IMAGE_PROGRESS) (
    IN UINTN Completion
) ;
Completion
```

A value between 1 and 100 indicating the current completion progress of the firmware update. Completion progress is reported as from 1 to 100 percent. A value of 0 is used by the driver to indicate that progress reporting is not supported.

On **EFI_SUCCESS**, **SetImage()** continues to do the callback if supported. On **NOT EFI_SUCCESS**, **SetImage()** discontinues the callback and completes the update and returns.

Description

This function updates the hardware with the new firmware image.

This function returns **EFI_UNSUPPORTED** if the firmware image is not updatable.

If the firmware image is updatable, the function should perform the following minimal validations before proceeding to do the firmware image update.

- Validate the image authentication if image has attribute **IMAGE_ATTRIBUTE_AUTHENTICATION_REQUIRED**. The function returns **EFI_SECURITY_VIOLATION** if the validation fails.
- Validate the image is a supported image for this device. The function returns **EFI_ABORTED** if the image is unsupported. The function can optionally provide more detailed information on why the image is not a supported image.
- Validate the data from *VendorCode* if not null. Image validation must be performed before *VendorCode* data validation. *VendorCode* data is ignored or considered invalid if image validation failed. The function returns **EFI_ABORTED** if the data is invalid.

VendorCode enables vendor to implement vendor-specific firmware image update policy. Null if the caller did not specify the policy or use the default policy. As an example, vendor can implement a policy to allow an option to force a firmware image update when the abort reason is due to the new firmware image version is older than the current firmware image version or bad image checksum. Sensitive operations such as those wiping the entire firmware image and render the device to be non-functional should be encoded in the image itself rather than passed with the *VendorCode*.

AbortReason enables vendor to have the option to provide a more detailed description of the abort reason to the caller.

Status Codes Returned

EFI_SUCCESS	The device was successfully updated with the new image.
EFI_ABORTED	The operation is aborted.
EFI_INVALID_PARAMETER	The <i>Image</i> was NULL.
EFI_UNSUPPORTED	The operation is not supported.

Unified Extensible Firmware Interface Specification

EFI_SECURITY_VIOLATION	The operation could not be performed due to an authentication failure.
------------------------	--

EFI_FIRMWARE_MANAGEMENT_PROTOCOL.CheckImage()

Summary

Checks if the firmware image is valid for the device.

Protocol

```
typedef
EFI_STATUS
(EFIAPI *EFI_FIRMWARE_MANAGEMENT_PROTOCOL_CHECK_IMAGE) (
    IN  EFI_FIRMWARE_MANAGEMENT_PROTOCOL  *This,
    IN  UINT8                               ImageIndex,
    IN  CONST VOID                          *Image,
    IN  UINTN                               ImageSize,
    OUT UINT32                              *ImageUpdatable
) ;
```

Parameters

This

A pointer to the **EFI_FIRMWARE_MANAGEMENT_PROTOCOL** instance.

ImageIndex

A unique number identifying the firmware image(s) within the device. The number is between 1 and *DescriptorCount*.

Image

Points to the new image.

ImageSize

Size of the new image in bytes.

ImageUpdatable

Indicates if the new image is valid for update. It also provides, if available, additional information if the image is invalid. See “Related Definitions”.

Related Definitions

```

//*****
// ImageUpdatable Definitions
//*****
#define  IMAGE_UPDATABLE_VALID            0x0000000000000001
#define  IMAGE_UPDATABLE_INVALID        0x0000000000000002
#define  IMAGE_UPDATABLE_INVALID_TYPE   0x0000000000000004
#define  IMAGE_UPDATABLE_INVALID_OLD    0x0000000000000008
#define  IMAGE_UPDATABLE_VALID_WITH_VENDOR_CODE \
0x0000000000000010
```

IMAGE_UPDATABLE_VALID indicates **SetImage ()** will accept the new image and update the device with the new image. The version of the new image could be higher or lower than the current image. **SetImage VendorCode** is optional but can be used for vendor specific action.

IMAGE_UPDATABLE_INVALID indicates **SetImage ()** will reject the new image. No additional information is provided for the rejection.

IMAGE_UPDATABLE_INVALID_TYPE indicates **SetImage ()** will reject the new image. The rejection is due to the new image is not a firmware image recognized for this device.

IMAGE_UPDATABLE_INVALID_OLD indicates **SetImage ()** will reject the new image. The rejection is due to the new image version is older than the current firmware image version in the device. The device firmware update policy does not support firmware version downgrade.

IMAGE_UPDATABLE_VALID_WITH_VENDOR_CODE indicates **SetImage ()** will accept and update the new image only if a correct *VendorCode* is provided or else image would be rejected and **SetImage** will return appropriate error.

Description

This function allows firmware update application to validate the firmware image without invoking the **SetImage ()** first. Please see **SetImage ()** for the type of image validations performed.

Status Codes Returned

EFI_SUCCESS	The image was successfully checked.
EFI_INVALID_PARAMETER	The <i>Image</i> was NULL.
EFI_UNSUPPORTED	The operation is not supported.
EFI_SECURITY_VIOLATION	The operation could not be performed due to an authentication failure.

EFI_FIRMWARE_MANAGEMENT_PROTOCOL.GetPackageInfo()

Summary

Returns information about the firmware package.

Protocol

```
typedef
EFI_STATUS
(EFIAPI *EFI_FIRMWARE_MANAGEMENT_PROTOCOL_GET_PACKAGE_INFO) (
    IN  EFI_FIRMWARE_MANAGEMENT_PROTOCOL *This,
    OUT UINT32                            *PackageVersion,
    OUT CHAR16                            **PackageVersionName,
    OUT UINT32                            *PackageVersionNameMaxLen,
    OUT UINT64                            *AttributesSupported,
    OUT UINT64                            *AttributesSetting
) ;
```

Parameters

This

A pointer to the **EFI_FIRMWARE_MANAGEMENT_PROTOCOL** instance.

PackageVersion

A version number that represents all the firmware images in the device. The format is vendor specific and new version must have a greater value than the old version. If *PackageVersion* is not supported, the value is 0xFFFFFFFF. A value of 0xFFFFFFFFE indicates that package version comparison is to be performed using *PackageVersionName*. A value of 0xFFFFFFFFD indicates that package version update is in progress.

PackageVersionName

A pointer to a pointer to a null-terminated string representing the package version name. The buffer is allocated by this function with **AllocatePool()**, and it is the caller's responsibility to free it with a call to **FreePool()**.

PackageVersionNameMaxLen

The maximum length of package version name if device supports update of package version name. A value of 0 indicates the device does not support update of package version name. Length is the number of Unicode characters, including the terminating null character.

AttributesSupported

Package attributes that are supported by this device. See “Package Attribute Definitions” for possible returned values of this parameter. A value of 1 indicates the attribute is supported and the current setting value is indicated in *AttributesSetting*. A value of 0 indicates the attribute is not supported and the current setting value in *AttributesSetting* is meaningless.

AttributesSetting

Package attributes. See “Package Attribute Definitions” for possible returned values of this parameter.

Related Definitions

```

//*****
// Package Attribute Definitions
//*****
#define PACKAGE_ATTRIBUTE_VERSION_UPDATABLE 0x0000000000000001
#define PACKAGE_ATTRIBUTE_RESET_REQUIRED 0x0000000000000002
#define PACKAGE_ATTRIBUTE_AUTHENTICATION_REQUIRED
0x0000000000000004
    
```

The attribute **PACKAGE_ATTRIBUTE_VERSION_UPDATABLE** indicates this device supports the update of the firmware package version.

The attribute **PACKAGE_ATTRIBUTE_RESET_REQUIRED** indicates a reset of the device is required for the new package info to take effect after an update.

The attribute **PACKAGE_ATTRIBUTE_AUTHENTICATION_REQUIRED** indicates authentication is required to update the package info.

Description

This function returns package information.

Status Codes Returned

EFI_SUCCESS	The package information was successfully returned.
EFI_UNSUPPORTED	The operation is not supported.

EFI_FIRMWARE_MANAGEMENT_PROTOCOL.SetPackageInfo()

Summary

Updates information about the firmware package.

Protocol

```
typedef
EFI_STATUS
(EFIAPI *EFI_FIRMWARE_MANAGEMENT_PROTOCOL_SET_PACKAGE_INFO) (
    IN  EFI_FIRMWARE_MANAGEMENT_PROTOCOL  *This,
    IN  CONST VOID                        *Image,
    IN  UINTN                             ImageSize,
    IN  CONST VOID                        *VendorCode,
    IN  UINT32                             PackageVersion,
    IN  CONST CHAR16                      *PackageVersionName
) ;
```

Parameters

This

A pointer to the `EFI_FIRMWARE_MANAGEMENT_PROTOCOL` instance.

Image

Points to the authentication image. Null if authentication is not required.

ImageSize

Size of the authentication image in bytes. 0 if authentication is not required.

VendorCode

This enables vendor to implement vendor-specific firmware image update policy. Null indicates the caller did not specify this policy or use the default policy.

PackageVersion

The new package version.

PackageVersionName

A pointer to the new null-terminated Unicode string representing the package version name. The string length is equal to or less than the value returned in *PackageVersionNameMaxLen*.

Description

This function updates package information.

This function returns `EFI_UNSUPPORTED` if the package information is not updatable.

VendorCode enables vendor to implement vendor-specific package information update policy. Null if the caller did not specify this policy or use the default policy.

Status Codes Returned

EFI_SUCCESS	The device was successfully updated with the new package information
EFI_INVALID_PARAMETER	The <i>PackageVersionName</i> length is longer than the value returned in <i>PackageVersionNameMaxLen</i> .
EFI_UNSUPPORTED	The operation is not supported.
EFI_SECURITY_VIOLATION	The operation could not be performed due to an authentication failure.

22.2 Delivering Capsules Containing Updates to Firmware Management Protocol

Summary

This section defines a method for delivery of a Firmware Management Protocol defined update using the UpdateCapsule runtime API.

22.2.1 EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID

GUID

```
// {6DCBD5ED-E82D-4C44-BDA1-7194199AD92A}
#define EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID \
    {0x6dcbd5ed, 0xe82d, 0x4c44, \
     {0xbd, 0xa1, 0x71, 0x94, 0x19, 0x9a, 0xd9, 0x2a } }
```

Description

This GUID is used in the *CapsuleGuid* field of **EFI_CAPSULE_HEADER** struct within a capsule constructed according to the definitions of section [Section 7.5.3.1](#). Use of this GUID indicates a capsule with body conforming to the additional structure defined in [Section 22.2.2](#).

When delivered to platform firmware **QueryCapsuleCapabilities ()** the capsule will be examined according to the structure defined in [Section 22.2.2](#) and if it is possible for the platform to process **EFI_SUCCESS** will be returned.

When delivered to platform firmware **UpdateCapsule ()** the capsule will be examined according to the structure defined in [Section 22.2.2](#) and if it is possible for the platform to process the update will be processed.

By definition Firmware Management protocol services are not available in EFI runtime and depending upon platform capabilities, EFI runtime delivery of this capsule may not be supported and may return an error when delivered in EFI runtime with **CAPSULE_FLAGS_PERSIST_ACROSS_RESET** bit defined. However any platform supporting this capability is required to accept this form of capsule in Boot Services, including optional use of **CAPSULE_FLAGS_PERSIST_ACROSS_RESET** bit.

22.2.2 DEFINED FIRMWARE MANAGEMENT PROTOCOL DATA CAPSULE STRUCTURE

Structure of the Capsule Body

Generic EFI Capsule Body is defined in [Section 7.5.3.1](#). When an EFI Capsule is identified by `EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID`, the internal structure of the capsule `EFI_FIRMWARE_MANAGEMENT_CAPSULE_HEADER` followed by optional EFI drivers to be loaded by the platform and optional binary payload items to be processed and passed to Firmware Management Protocol image update function. Each binary payload item is preceded by `EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER`. Internal capsule structure diagram follows.

Related Definitions

```
#pragma pack(1)
typedef struct {
    UINT32      Version;
    UINT16      EmbeddedDriverCount;
    UINT16      PayloadItemCount;
    // UINT64    ItemOffsetList[];
} EFI_FIRMWARE_MANAGEMENT_CAPSULE_HEADER;
```

Version

Version of the structure, initially 0x00000001.

EmbeddedDriverCount

The number of drivers included in the capsule and the number of corresponding offsets stored in *ItemOffsetList* array. This field may be zero in the case where no driver is required.

PayloadItemCount

The number of payload items included in the capsule and the number of corresponding offsets stored in the *ItemOffsetList* array. This field may be zero in the case where no binary payload object is required to accomplish the update.

ItemOffsetList

Variable length array of dimension [*EmbeddedDriverCount* + *PayloadItemCount*] containing offsets of each of the drivers and payload items contained within the capsule. The offsets of the items are calculated relative to the base address of the **EFI_FIRMWARE_MANAGEMENT_CAPSULE_HEADER** struct. Offset may indicate structure begins on any byte boundary. Offsets in the array must be sorted in ascending order with all drivers preceding all binary payload elements.

```
#pragma pack(1)
typedef struct {
    UINT32      Version;
    EFI_GUID    UpdateImageTypeId;
    UINT8       UpdateImageIndex;
    UINT8       reserved_bytes[3];
    UINT32      UpdateImageSize;
    UINT32      UpdateVendorCodeSize;
    UINT64      UpdateHardwareInstance; //Introduced in v2
} EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER;
```

Version

Version of the structure, initially **0x00000002**.

UpdateImageTypeId

Used to identify device firmware targeted by this update. This guid is matched by system firmware against *ImageTypeId* field within a **EFI_FIRMWARE_IMAGE_DESCRIPTOR** returned by an instance of **EFI_FIRMWARE_MANAGEMENT_PROTOCOL.GetImageInfo()** in the system.

UpdateImageIndex

Passed as *ImageIndex* in call to **EFI_FIRMWARE_MANAGEMENT_PROTOCOL.SetImage()**

UpdateImageSize

Size of the binary update image which immediately follows this structure. Passed as *ImageSize* to **EFI_FIRMWARE_MANAGEMENT_PROTOCOL.SetImage()**. This size may or may not include Firmware Image Authentication information.

UpdateVendorCodeSize

Size of the *VendorCode* bytes which optionally immediately follow binary update image in the capsule. Pointer to these bytes passed in *VendorCode* to **EFI_FIRMWARE_MANAGEMENT_PROTOCOL.SetImage()**. If *UpdateVendorCodeSize* is zero, then *VendorCode* is null in **SetImage()** call.

UpdateHardwareInstance

The *HardwareInstance* to target with this update. If value is zero it means match all *HardwareInstances*. This field allows update software to target only a single device in cases where there are more than one device with the same *ImageTypeId*

GUID. This header is outside the signed data of the Authentication Info structure and therefore can be modified without changing the Auth data.

Description

The **EFI_FIRMWARE_MANAGEMENT_CAPSULE_HEADER** structure is located at the lowest offset within the body of the capsule identified by **EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID**. The structure is variable length with the number of element offsets within of the *ItemOffsetList* array determined by the count of drivers within the capsule plus the count of binary payload elements. It is expected that drivers whose presence is indicated by non-zero *EmbeddedDriverCount* will be used to supply an implementation of **EFI_FIRMWARE_MANAGEMENT_PROTOCOL** for devices that lack said protocol within the image to be updated.

Each payload item contained within the capsule body is preceded by a **EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER** struct used to provide information required to prepare the payload item as an image for delivery to a instance of **EFI_FIRMWARE_MANAGEMENT_PROTOCOL.SetImage()** function.

Note: [Caution] The capsule identified by **EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID** uses packed structures and structure fields may not be naturally aligned within the capsule buffer as delivered. Drivers and binary payload elements may start on byte boundary with no padding. Processing firmware may need to copy content elements during capsule unpacking in order to achieve any required natural alignment.

22.2.3 Firmware Processing of the Capsule Identified by **EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID**

1. Capsule is presented to system firmware via call to **UpdateCapsule()** or using mass storage delivery procedure of [Section 7.5.5](#). The capsule must be constructed to consist of a single **EFI_FIRMWARE_MANAGEMENT_CAPSULE_HEADER** structure with the 0 or more drivers and 0 or more binary payload items. However a capsule in which driver count and payload count are both zero is not processed.
2. Capsule is recognized by **EFI_CAPSULE_HEADER** member *CapsuleGuid* equal to **EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID**. **CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE** flag must be 0.
3. If system is not in boot services and platform does not support persistence of capsule across reset when initiated within EFI Runtime, **EFI_OUT_OF_RESOURCES** error is returned.
4. If device requires hardware reset to unlock flash write protection, **CAPSULE_FLAGS_PERSIST_ACROSS_RESET** and optionally **CAPSULE_FLAGS_INITIATE_RESET** should be set to 1 in the **EFI_CAPSULE_HEADER**.
5. When reset is requested using **CAPSULE_FLAGS_PERSIST_ACROSS_RESET**, the capsule is processed in Boot Services, before the **EFI_EVENT_GROUP_READY_TO_BOOT** event.
6. All scatter-gather fragmentation is removed by the platform firmware and the capsule is processed as a contiguous buffer.
7. Examining **EFI_FIRMWARE_MANAGEMENT_CAPSULE_HEADER**, if *EmbeddedDriverCount* is non-zero, for each of the included drivers up to indicated count, the portion of the capsule body starting at the offset indicated by *ItemOffsetList[n]* and continuing for a size encompassing all bytes up to the next element's offset stored in

ItemOffsetList[n+1] or the end of the capsule, will be copied to a buffer. The driver contained within the capsule body may not be naturally aligned and the exact driver size in bytes should be respected to ensure successful security validation. In the case where a driver is last element in the *ItemOffsetList* array, the driver size may be calculated by reference to body size as calculated from *CapsuleImageSize* in **EFI_CAPSULE_HEADER**

8. Each extracted driver is placed into a buffer and passed to **LoadImage()**. The driver image passed to **LoadImage()** must successfully pass all image format, platform type, and security checks including those related to UEFI secure boot, if enabled on the platform. After **LoadImage()** returns the processing of the capsule is continued with next driver if present until all drivers have been passed to **LoadImage()**. The driver being installed must check for matching hardware and instantiate any required protocols during call to **EFI_IMAGE_ENTRY_POINT**. In case where matching hardware is not found the driver should exit with error. In case where capsule creator has preference as to which of several included drivers to be made resident, later drivers in the capsule should confirm earlier driver successfully loaded and then exit with load error.
9. After driver processing is complete the platform firmware examines *PayloadItemCount*, and if zero the capsule processing is complete. Otherwise platform firmware sequentially locates each **EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER** found within the capsule and processes according to steps 10-14.
10. For all instances of **EFI_FIRMWARE_MANAGEMENT_PROTOCOL** in the system, **GetImageInfo()** is called to return arrays of **EFI_FIRMWARE_IMAGE_DESCRIPTOR** structures.
11. Find the matching FMP instance(s):
 - a. If the **EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER** is version 1 or it is version 2 with *UpdateHardwareInstance* set to 0, then system firmware will use only the *ImageTypeId* to determine a match. For each instance of **EFI_FIRMWARE_MANAGEMENT_PROTOCOL** that returns a **EFI_FIRMWARE_IMAGE_DESCRIPTOR** containing an *ImageTypeId* GUID that matches the *UpdateImageTypeId* GUID within **EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER**, the system firmware will call **SetImage()** function within that instance. In some cases there may be more than one instance of matching **EFI_FIRMWARE_MANAGEMENT_PROTOCOL** when multiple matching devices are installed in the system and all instances will be checked for GUID match and **SetImage()** call if match is successful.
 - b. If the **EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER** is version 2 and contains a non-zero value in the *UpdateHardwareInstance* field, then system firmware will use both *ImageTypeId* and *HardwareInstance* to determine a match. For the instance of **EFI_FIRMWARE_MANAGEMENT_PROTOCOL** that returns a **EFI_FIRMWARE_IMAGE_DESCRIPTOR** containing an *ImageTypeId* GUID that matches the *UpdateImageTypeId* GUID and a *HardwareInstance* matching the *UpdateHardwareInstance* within **EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER**, the system firmware will call the **SetImage()** function within that instance. There will never be more than one instance since the *ImageId* must be unique.
12. In the situation where platform configuration or policy prohibits the processing of a capsule or individual FMP payload, the error **EFI_NOT_READY** will be returned in capsule result variable *CapsuleStatus* field. Otherwise **SetImage()** parameters are constructed using the

UpdateImageIndex, *UpdateImageSize* and *UpdateVendorCodeSize* fields within **EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER**. In the case of capsule containing multiple payloads, or a payload matching multiple FMP instances, a separate Capsule Result Variable will be created with the results of each call to **SetImage()**. If any call to **SetImage()** selected per above matching algorithm returns an error, the processing of additional FMP instances or payload items in that capsule will be skipped and **EFI_ABORTED** returned in Capsule Result Variable for each potential call to **SetImage()** that was skipped.

13. **SetImage()** performs any required image authentication as described in that functions definition within this chapter.
14. Note: if multiple separate component updates including multiple *ImageIndex* values are required then additional **EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER** structures and image binaries are included within the capsule.
15. After all items in the capsule are processed the system is restarted by the platform firmware.

22.3 EFI System Resource Table

EFI_SYSTEM_RESOURCE_TABLE

Summary

The EFI System Resource Table (ESRT) provides an optional mechanism for identifying device and system firmware resources for the purposes of targeting firmware updates to those resources. Each entry in the ESRT describes a device or system firmware resource that can be targeted by a firmware capsule update. Each entry in the ESRT will also be used to report status of the last attempted update. See [Section 4.6](#) for description of how to publish ESRT using **EFI_CONFIGURATION_TABLE**. The ESRT shall be stored in memory of type **EfiBootServicesData**. See [Section 7.5.3](#) and [Section 7.5.5](#) for details on delivery of updates to devices listed in ESRT.

GUID

```
#define EFI_SYSTEM_RESOURCE_TABLE_GUID\
    { 0xb122a263, 0x3661, 0x4f68, \
      { 0x99, 0x29, 0x78, 0xf8, 0xb0, 0xd6, 0x21, 0x80 } }
```

Table Structure

```
typedef struct {
    UINT32                FwResourceCount;
    UINT32                FwResourceCountMax;
    UINT64                FwResourceVersion;
    //EFI_SYSTEM_RESOURCE_ENTRY Entries[];
} EFI_SYSTEM_RESOURCE_TABLE;
```

Members

<i>FwResourceCount</i>	The number of firmware resources in the table, must not be zero.
<i>FwResourceCountMax</i>	The maximum number of resource array entries that can be within the table without reallocating the table, must not be zero.

FwResourceVersion The version of the **EFI_SYSTEM_RESOURCE_ENTRY** entities used in this table. This field should be set to 1. See **EFI_SYSTEM_RESOURCE_TABLE_FIRMWARE_RESOURCE_VERSION**.

Entries Array of **EFI_SYSTEM_RESOURCE_ENTRY**

Related Definitions

```
// Current Entry Version
#define EFI_SYSTEM_RESOURCE_TABLE_FIRMWARE_RESOURCE_VERSION 1

typedef struct {
    EFI_GUID          FwClass;
    UINT32            FwType;
    UINT32            FwVersion;
    UINT32            LowestSupportedFwVersion;
    UINT32            CapsuleFlags;
    UINT32            LastAttemptVersion;
    UINT32            LastAttemptStatus;
} EFI_SYSTEM_RESOURCE_ENTRY;
```

FwClass The firmware class field contains a GUID that identifies a firmware component that can be updated via **UpdateCapsule ()**. This GUID must be unique within all entries of the ESRT.

FwType Identifies the type of firmware resource. See “Firmware Type Definitions” below for possible values.

FwVersion The firmware version field represents the current version of the firmware resource, value must always increase as a larger number represents a newer version.

LowestSupportedFwVersion The lowest firmware resource version to which a firmware resource can be rolled back for the given system/device. Generally this is used to protect against known and fixed security issues.

CapsuleFlags The capsule flags field contains the *CapsuleGuid* flags (bits 0-15) as defined in the **EFI_CAPSULE_HEADER** that will be set in the capsule header.

LastAttemptVersion The last attempt version field describes the last firmware version for which an update was attempted (uses the same format as Firmware Version).
Last Attempt Version is updated each time an **UpdateCapsule ()** is attempted for an ESRT entry and is preserved across reboots (non-volatile). However, in cases where the attempt version is not recorded due to limitations in the update process, the field shall set to zero after a failed update. Similarly, in the case of a removable device, this value is set to 0

in cases where the device has not been updated since being added to the system.

LastAttemptStatus The last attempt status field describes the result of the last firmware update attempt for the firmware resource entry.

LastAttemptStatus is updated each time an **UpdateCapsule ()** is attempted for an ESRT entry and is preserved across reboots (non-volatile).

If a firmware update has never been attempted or is unknown, for example after fresh insertion of a removable device,

LastAttemptStatus must be set to Success.

```
//
// Firmware Type Definitions
//
#define ESRT_FW_TYPE_UNKNOWN          0x00000000
#define ESRT_FW_TYPE_SYSTEMFIRMWARE  0x00000001
#define ESRT_FW_TYPE_DEVICEFIRMWARE  0x00000002
#define ESRT_FW_TYPE_UEFIDRIVER      0x00000003

//
// Last Attempt Status Values
//
#define LAST_ATTEMPT_STATUS_SUCCESS   0x00000000
#define LAST_ATTEMPT_STATUS_ERROR_UNSUCCESSFUL 0x00000001
#define LAST_ATTEMPT_STATUS_ERROR_INSUFFICIENT_RESOURCES 0x00000002
#define LAST_ATTEMPT_STATUS_ERROR_INCORRECT_VERSION 0x00000003
#define LAST_ATTEMPT_STATUS_ERROR_INVALID_FORMAT 0x00000004
#define LAST_ATTEMPT_STATUS_ERROR_AUTH_ERROR 0x00000005
#define LAST_ATTEMPT_STATUS_ERROR_PWR_EVT_AC 0x00000006
#define LAST_ATTEMPT_STATUS_ERROR_PWR_EVT_BATT 0x00000007
```

22.3.1 Adding and Removing Devices from the ESRT

ESRT entries must be updated by System Firmware before handoff to the Operating System under the following conditions. Devices and systems that support hot swapping (once the OS has been loaded) will not get their ESRT entries updated until the next reboot and execution of ESRT updating logic in the UEFI space.

Required: System firmware is responsible for updating the *FirmwareVersion*, *LowestSupportedFirmwareVersion*,

LastAttemptVersion and *LastAttemptStatus* values in the ESRT any time **UpdateCapsule** is called and a firmware update attempt is made for the corresponding ESRT entry.

Required: the ESRT must be updated each time a configuration change is detected by system firmware, such as when a device is added or removed from the system.

Optional: all devices in the ESRT should be polled for any configuration changes any time **UpdateCapsule** is called.

22.3.2 ESRT and Firmware Management Protocol

Although the ESRT does not require firmware to use Firmware Management Protocol for updates it is designed to work with and extend the capabilities of FMP. The ESRT can be used to represent system and device firmware serviced by capsules that have an implementation specific format as well as devices that support Firmware Management Protocol and that are serviced by capsules formatted as described in [Section 22.2](#), Delivering Capsules Containing Updates to Firmware Management Protocol. For system expansion devices, the task of building ESRT table entries is to be performed by the system firmware based upon FMP data published by the device.

22.3.3 Mapping Firmware Management Protocol Descriptors to ESRT Entries

Firmware management Protocol descriptors define most of the information needed for an ESRT entry. The table below helps identify which members map to which fields. Some members are dependent on certain versions of FMP and it is left to system firmware to resolve any mappings when information is not present in the FMP instance. FMP descriptors should only be mapped to ESRT entries if the following are true:

- An entry with the same *ImageTypeId* is not already in the ESRT.
- *AttributesSupported* and *AttributesSetting* have the **IMAGE_ATTRIBUTE_IN_USE** bit set.
- In the case where *DescriptorCount* returned by **GetImageInfo()** is greater than one, firmware shall populate the ESRT according to system policy, noting however that multiple ESRT entries with identical FwClass values are not permitted.

ESRT Field	FMP Field	Comment
<i>FwClass</i>	<i>ImageTypeId</i>	The ImageTypeId GUID from the Firmware Management Protocol instance for a device is used as the Firmware Class GUID in the ESRT. Where there are multiple identical devices in the system, system firmware must create a mapping to ensure that the ESRT FwClass GUIDs are unique and consistent.
<i>FwVersion</i>	<i>Version</i>	Represents the current version of device firmware for an FMP instance.

ESRT Field	FMP Field	Comment
<i>LowestSupportedFwVersion</i>	<i>LowestSupportedImageVersion</i>	
<i>LastAttemptVersion</i>	<i>LastAttemptVersion</i>	To be set after the completion of a firmware update attempt. In descriptor v3+ only. Default value is 0.
<i>LastAttemptStatus</i>	<i>LastAttemptStatus</i>	To be set after the completion of a firmware update attempt. In descriptor v3+ only. Default value is SUCCESS.

Table 188. ESRT and FMP Fields

23 Network Protocols — SNP, PXE, BIS and HTTP Boot

23.1 Simple Network Protocol

This section defines the Simple Network Protocol. This protocol provides a packet level interface to a network adapter.

EFI_SIMPLE_NETWORK_PROTOCOL

Summary

The **EFI_SIMPLE_NETWORK_PROTOCOL** provides services to initialize a network interface, transmit packets, receive packets, and close a network interface.

GUID

```
#define EFI_SIMPLE_NETWORK_PROTOCOL_GUID \
    { 0xA19832B9, 0xAC25, 0x11D3, \
      { 0x9A, 0x2D, 0x00, 0x90, 0x27, 0x3f, 0xc1, 0x4d } }
```

Revision Number

```
#define EFI_SIMPLE_NETWORK_PROTOCOL_REVISION 0x00010000
```

Protocol Interface Structure

```
typedef struct _EFI_SIMPLE_NETWORK_PROTOCOL_ {
    UINT64 Revision;
    EFI_SIMPLE_NETWORK_START Start;
    EFI_SIMPLE_NETWORK_STOP Stop;
    EFI_SIMPLE_NETWORK_INITIALIZE Initialize;
    EFI_SIMPLE_NETWORK_RESET Reset;
    EFI_SIMPLE_NETWORK_SHUTDOWN Shutdown;
    EFI_SIMPLE_NETWORK_RECEIVE_FILTERS ReceiveFilters;
    EFI_SIMPLE_NETWORK_STATION_ADDRESS StationAddress;
    EFI_SIMPLE_NETWORK_STATISTICS Statistics;
    EFI_SIMPLE_NETWORK_MCAST_IP_TO_MAC MCastIpToMac;
    EFI_SIMPLE_NETWORK_NVDATA NvData;
    EFI_SIMPLE_NETWORK_GET_STATUS GetStatus;
    EFI_SIMPLE_NETWORK_TRANSMIT Transmit;
    EFI_SIMPLE_NETWORK_RECEIVE Receive;
    EFI_EVENT WaitForPacket;
    EFI_SIMPLE_NETWORK_MODE *Mode;
} EFI_SIMPLE_NETWORK_PROTOCOL;
```

Parameters

<i>Revision</i>	Revision of the EFI_SIMPLE_NETWORK_PROTOCOL . All future revisions must be backwards compatible. If a future version is not backwards compatible it is not the same GUID.
<i>Start</i>	Prepares the network interface for further command operations. No other EFI_SIMPLE_NETWORK_PROTOCOL interface functions will operate until this call is made. See the Start() function description.
<i>Stop</i>	Stops further network interface command processing. No other EFI_SIMPLE_NETWORK_PROTOCOL interface functions will operate after this call is made until another Start() call is made. See the Stop() function description.
<i>Initialize</i>	Resets the network adapter and allocates the transmit and receive buffers. See the Initialize() function description.
<i>Reset</i>	Resets the network adapter and reinitializes it with the parameters provided in the previous call to Initialize() . See the Reset() function description.

<i>Shutdown</i>	Resets the network adapter and leaves it in a state safe for another driver to initialize. The memory buffers assigned in the Initialize () call are released. After this call, only the Initialize () or Stop () calls may be used. See the Shutdown () function description.
<i>ReceiveFilters</i>	Enables and disables the receive filters for the network interface and, if supported, manages the filtered multicast HW MAC (Hardware Media Access Control) address list. See the ReceiveFilters () function description.
<i>StationAddress</i>	Modifies or resets the current station address, if supported. See the StationAddress () function description.
<i>Statistics</i>	Collects statistics from the network interface and allows the statistics to be reset. See the Statistics () function description.
<i>MCastIpToMac</i>	Maps a multicast IP address to a multicast HW MAC address. See the MCastIPtoMAC () function description.
<i>NvData</i>	Reads and writes the contents of the NVRAM devices attached to the network interface. See the NvData () function description.
<i>GetStatus</i>	Reads the current interrupt status and the list of recycled transmit buffers from the network interface. See the GetStatus () function description.
<i>Transmit</i>	Places a packet in the transmit queue. See the Transmit () function description.
<i>Receive</i>	Retrieves a packet from the receive queue, along with the status flags that describe the packet type. See the Receive () function description.
<i>WaitForPacket</i>	Event used with EFI_BOOT_SERVICES.WaitForEvent () to wait for a packet to be received.
<i>Mode</i>	Pointer to the EFI_SIMPLE_NETWORK_MODE data for the device. See “Related Definitions” below.

Related Definitions

// functions. All these fields must be discovered
// in a protocol instance of
// EFI_DRIVER_BINDING_PROTOCOL.Start().
//*****
typedef struct {
    UINT32                State;
    UINT32                HwAddressSize;
    UINT32                MediaHeaderSize;
    UINT32                MaxPacketSize;
    UINT32                NvRamSize;
    UINT32                NvRamAccessSize;
    UINT32                ReceiveFilterMask;
    UINT32                ReceiveFilterSetting;
    UINT32                MaxMCastFilterCount;
    UINT32                MCastFilterCount;
    EFI_MAC_ADDRESS       MCastFilter[MAX_MCAST_FILTER_CNT];
    EFI_MAC_ADDRESS       CurrentAddress;
    EFI_MAC_ADDRESS       BroadcastAddress;
    EFI_MAC_ADDRESS       PermanentAddress;
    UINT8                 IfType;
    BOOLEAN                MacAddressChangeable;
    BOOLEAN                MultipleTxSupported;
    BOOLEAN                MediaPresentSupported;
    BOOLEAN                MediaPresent;
} EFI_SIMPLE_NETWORK_MODE;

```

<i>State</i>	Reports the current state of the network interface (see EFI_SIMPLE_NETWORK_STATE below). When an EFI_SIMPLE_NETWORK_PROTOCOL driver initializes a network interface, the network interface is left in the EfiSimpleNetworkStopped state.
<i>HwAddressSize</i>	The size, in bytes, of the network interface’s HW address.
<i>MediaHeaderSize</i>	The size, in bytes, of the network interface’s media header.
<i>MaxPacketSize</i>	The maximum size, in bytes, of the packets supported by the network interface.
<i>NvRamSize</i>	The size, in bytes, of the NVRAM device attached to the network interface. If an NVRAM device is not attached to the network interface, then this field will be zero. This value must be a multiple of <i>NvramAccessSize</i> .

<i>NvRamAccessSize</i>	The size that must be used for all NVRAM reads and writes. The start address for NVRAM read and write operations and the total length of those operations, must be a multiple of this value. The legal values for this field are 0, 1, 2, 4, and 8. If the value is zero, then no NVRAM devices are attached to the network interface.
<i>ReceiveFilterMask</i>	The multicast receive filter settings supported by the network interface.
<i>ReceiveFilterSetting</i>	The current multicast receive filter settings. See “Bit Mask Values for <i>ReceiveFilterSetting</i> ” below.
<i>MaxMCastFilterCount</i>	The maximum number of multicast address receive filters supported by the driver. If this value is zero, then <i>ReceiveFilters()</i> cannot modify the multicast address receive filters. This field may be less than MAX_MCAST_FILTER_CNT (see below).
<i>MCastFilterCount</i>	The current number of multicast address receive filters.
<i>MCastFilter</i>	Array containing the addresses of the current multicast address receive filters.
<i>CurrentAddress</i>	The current HW MAC address for the network interface.
<i>BroadcastAddress</i>	The current HW MAC address for broadcast packets.
<i>PermanentAddress</i>	The permanent HW MAC address for the network interface.
<i>IfType</i>	The interface type of the network interface. See RFC 3232, section “Number Hardware Type.”
<i>MacAddressChangeable</i>	TRUE if the HW MAC address can be changed.
<i>MultipleTxSupported</i>	TRUE if the network interface can transmit more than one packet at a time.
<i>MediaPresentSupported</i>	TRUE if the presence of media can be determined; otherwise FALSE . If FALSE , MediaPresent cannot be used.
<i>MediaPresent</i>	TRUE if media are connected to the network interface; otherwise FALSE . This field shows the media present status as of the most recent GetStatus () call.

```

Description

The **EFI_SIMPLE_NETWORK_PROTOCOL** protocol is used to initialize access to a network adapter. Once the network adapter initializes, the **EFI_SIMPLE_NETWORK_PROTOCOL** protocol provides services that allow packets to be transmitted and received. This provides a packet level interface that can then be used by higher level drivers to produce boot services like DHCP, TFTP, and MFTFTP. In addition, this protocol can be used as a building block in a full UDP and TCP/IP implementation that can produce a wide variety of application level network interfaces. See the *Preboot Execution Environment (PXE) Specification* for more information.

Note: *The underlying network hardware may only be able to access 4 GiB (32-bits) of system memory. Any requests to transfer data to/from memory above 4 GiB with 32-bit network hardware will be double-buffered (using intermediate buffers below 4 GiB) and will reduce performance.*

Note: *The same handle can have an instance of the **EFI_ADAPTER_INFORMATION_PROTOCOL** with a **EFI_ADAPTER_INFO_MEDIA_STATE** type structure.*

EFI_SIMPLE_NETWORK.Start()

Summary

Changes the state of a network interface from “stopped” to “started.”

Prototype

```

typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_NETWORK_START) (
    IN EFI_SIMPLE_NETWORK_PROTOCOL    *This
);

```

Parameters

This

A pointer to the [EFI SIMPLE NETWORK PROTOCOL](#) instance.

Description

This function starts a network interface. If the network interface successfully starts, then **EFI_SUCCESS** will be returned.

Status Codes Returned

EFI_SUCCESS	The network interface was started.
EFI_ALREADY_STARTED	The network interface is already in the started state.
EFI_INVALID_PARAMETER	<i>This</i> parameter was NULL or did not point to a valid <code>EFI_SIMPLE_NETWORK_PROTOCOL</code> structure.
EFI_DEVICE_ERROR	The command could not be sent to the network interface.
EFI_UNSUPPORTED	This function is not supported by the network interface.

EFI_SIMPLE_NETWORK.Stop()

Summary

Changes the state of a network interface from “started” to “stopped.”

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_NETWORK_STOP) (
    IN EFI_SIMPLE_NETWORK_PROTOCOL    *This
);
```

Parameters

This A pointer to the [EFI SIMPLE NETWORK PROTOCOL](#) instance.

Description

This function stops a network interface. This call is only valid if the network interface is in the started state. If the network interface was successfully stopped, then **EFI_SUCCESS** will be returned.

Status Codes Returned

EFI_SUCCESS	The network interface was stopped.
EFI_NOT_STARTED	The network interface has not been started.
EFI_INVALID_PARAMETER	<i>This</i> parameter was NULL or did not point to a valid <code>EFI_SIMPLE_NETWORK_PROTOCOL</code> structure.
EFI_DEVICE_ERROR	The command could not be sent to the network interface.
EFI_UNSUPPORTED	This function is not supported by the network interface.

EFI_SIMPLE_NETWORK.Initialize()

Summary

Resets a network adapter and allocates the transmit and receive buffers required by the network interface; optionally, also requests allocation of additional transmit and receive buffers.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_NETWORK_INITIALIZE) (
    IN EFI_SIMPLE_NETWORK_PROTOCOL *This,
    IN UINTN                        ExtraRxBufferSize OPTIONAL,
    IN UINTN                        ExtraTxBufferSize OPTIONAL
);
```

Parameters

<i>This</i>	A pointer to the EFI_SIMPLE_NETWORK_PROTOCOL instance.
<i>ExtraRxBufferSize</i>	The size, in bytes, of the extra receive buffer space that the driver should allocate for the network interface. Some network interfaces will not be able to use the extra buffer, and the caller will not know if it is actually being used.
<i>ExtraTxBufferSize</i>	The size, in bytes, of the extra transmit buffer space that the driver should allocate for the network interface. Some network interfaces will not be able to use the extra buffer, and the caller will not know if it is actually being used.

Description

This function allocates the transmit and receive buffers required by the network interface. If this allocation fails, then **EFI_OUT_OF_RESOURCES** is returned. If the allocation succeeds and the network interface is successfully initialized, then **EFI_SUCCESS** will be returned.

Status Codes Returned

EFI_SUCCESS	The network interface was initialized.
EFI_NOT_STARTED	The network interface has not been started.
EFI_OUT_OF_RESOURCES	There was not enough memory for the transmit and receive buffers.
EFI_INVALID_PARAMETER	<i>This</i> parameter was NULL or did not point to a valid <code>EFI_SIMPLE_NETWORK_PROTOCOL</code> structure.
EFI_DEVICE_ERROR	The command could not be sent to the network interface.
EFI_UNSUPPORTED	The increased buffer size feature is not supported.

EFI_SIMPLE_NETWORK.Reset()

Summary

Resets a network adapter and reinitializes it with the parameters that were provided in the previous call to [Initialize\(\)](#).

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_NETWORK_RESET) (
    IN EFI_SIMPLE_NETWORK_PROTOCOL *This,
    IN BOOLEAN                      ExtendedVerification
);
```

Parameters

This A pointer to the [EFI SIMPLE NETWORK PROTOCOL](#) instance.

ExtendedVerification Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

This function resets a network adapter and reinitializes it with the parameters that were provided in the previous call to **Initialize()**. The transmit and receive queues are emptied and all pending interrupts are cleared. Receive filters, the station address, the statistics, and the multicast-IP-to-HW MAC addresses are not reset by this call. If the network interface was successfully reset, then **EFI_SUCCESS** will be returned. If the driver has not been initialized, **EFI_DEVICE_ERROR** will be returned.

Status Codes Returned

EFI_SUCCESS	The network interface was reset.
EFI_NOT_STARTED	The network interface has not been started.
EFI_INVALID_PARAMETER	One or more of the parameters has an unsupported value.
EFI_DEVICE_ERROR	The command could not be sent to the network interface.
EFI_UNSUPPORTED	This function is not supported by the network interface.

EFI_SIMPLE_NETWORK.Shutdown()

Summary

Resets a network adapter and leaves it in a state that is safe for another driver to initialize.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_NETWORK_SHUTDOWN) (
    IN EFI_SIMPLE_NETWORK_PROTOCOL      *This
);
```

Parameters

This A pointer to the [EFI SIMPLE NETWORK PROTOCOL](#) instance.

Description

This function releases the memory buffers assigned in the [Initialize\(\)](#) call. Pending transmits and receives are lost, and interrupts are cleared and disabled. After this call, only the [Initialize\(\)](#) and [Stop\(\)](#) calls may be used. If the network interface was successfully shutdown, then **EFI_SUCCESS** will be returned. If the driver has not been initialized, **EFI_DEVICE_ERROR** will be returned.

Status Codes Returned

EFI_SUCCESS	The network interface was shutdown.
EFI_NOT_STARTED	The network interface has not been started.
EFI_INVALID_PARAMETER	<i>This</i> parameter was NULL or did not point to a valid EFI_SIMPLE_NETWORK_PROTOCOL structure.
EFI_DEVICE_ERROR	The command could not be sent to the network interface.

EFI_SIMPLE_NETWORK.ReceiveFilters()

Summary

Manages the multicast receive filters of a network interface.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_NETWORK_RECEIVE_FILTERS) (
    IN EFI_SIMPLE_NETWORK_PROTOCOL    *This,
    IN UINT32                          Enable,
    IN UINT32                          Disable,
    IN BOOLEAN                          ResetMCastFilter,
    IN UINTN                            MCastFilterCnt OPTIONAL,
    IN EFI_MAC_ADDRESS                  *MCastFilter OPTIONAL,
);
```

Parameters

<i>This</i>	A pointer to the EFI_SIMPLE_NETWORK_PROTOCOL instance.
<i>Enable</i>	A bit mask of receive filters to enable on the network interface.
<i>Disable</i>	A bit mask of receive filters to disable on the network interface. For backward compatibility with EFI 1.1 platforms, the EFI_SIMPLE_NETWORK_RECEIVE_MULTICAST bit must be set when the <i>ResetMCastFilter</i> parameter is TRUE .
<i>ResetMCastFilter</i>	Set to TRUE to reset the contents of the multicast receive filters on the network interface to their default values.
<i>MCastFilterCnt</i>	Number of multicast HW MAC addresses in the new <i>MCastFilter</i> list. This value must be less than or equal to the <i>MCastFilterCnt</i> field of EFI_SIMPLE_NETWORK_MODE . This field is optional if <i>ResetMCastFilter</i> is TRUE .
<i>MCastFilter</i>	A pointer to a list of new multicast receive filter HW MAC addresses. This list will replace any existing multicast HW MAC address list. This field is optional if <i>ResetMCastFilter</i> is TRUE .

Description

This function is used enable and disable the hardware and software receive filters for the underlying network device.

The receive filter change is broken down into three steps:

- The filter mask bits that are set (ON) in the Enable parameter are added to the current receive filter settings.
- The filter mask bits that are set (ON) in the Disable parameter are subtracted from the updated receive filter settings.

- If the resulting receive filter setting is not supported by the hardware a more liberal setting is selected.

If the same bits are set in the Enable and Disable parameters, then the bits in the Disable parameter takes precedence.

If the ResetMCastFilter parameter is TRUE, then the multicast address list filter is disabled (irregardless of what other multicast bits are set in the Enable and Disable parameters). The Snp->Mode->MCastFilterCount field is set to zero. The Snp->Mode->MCastFilter contents are undefined.

After enabling or disabling receive filter settings, software should verify the new settings by checking the Snp->Mode->ReceiveFilterSettings, Snp->Mode->MCastFilterCount and Snp->Mode->MCastFilter fields.

Note: Some network drivers and/or devices will automatically promote receive filter settings if the requested setting can not be honored. For example, if a request for four multicast addresses is made and the underlying hardware only supports two multicast addresses the driver might set the promiscuous or promiscuous multicast receive filters instead. The receiving software is responsible for discarding any extra packets that get through the hardware receive filters.

Note: *Note: To disable all receive filter hardware, the network driver must be Shutdown() and Stopped(). Calling ReceiveFilters() with Disable set to Snp->Mode->ReceiveFilterSettings will make it so no more packets are returned by the Receive() function, but the receive hardware may still be moving packets into system memory before inspecting and discarding them. Unexpected system errors, reboots and hangs can occur if an OS is loaded and the network devices are not Shutdown() and Stopped().*

If **ResetMCastFilter** is **TRUE**, then the multicast receive filter list on the network interface will be reset to the default multicast receive filter list. If **ResetMCastFilter** is **FALSE**, and this network interface allows the multicast receive filter list to be modified, then the **MCastFilterCnt** and **MCastFilter** are used to update the current multicast receive filter list. The modified receive filter list settings can be found in the **MCastFilter** field of [EFI SIMPLE NETWORK MODE](#). If the network interface does not allow the multicast receive filter list to be modified, then **EFI_INVALID_PARAMETER** will be returned. If the driver has not been initialized, **EFI_DEVICE_ERROR** will be returned.

If the receive filter mask and multicast receive filter list have been successfully updated on the network interface, **EFI_SUCCESS** will be returned.

Status Codes Returned

EFI_SUCCESS	The multicast receive filter list was updated.
EFI_NOT_STARTED	The network interface has not been started.

Unified Extensible Firmware Interface Specification

EFI_INVALID_PARAMETER	<ul style="list-style-type: none"> • One or more of the following conditions is TRUE: • <i>This</i> is NULL • There are bits set in Enable that are not set in Snp->Mode->ReceiveFilterMask • There are bits set in Disable that are not set in Snp->Mode->ReceiveFilterMask • Multicast is being enabled (the EFI_SIMPLE_NETWORK_RECEIVE_MULTICAST bit is set in Enable, it is not set in Disable, and ResetMCastFilter is FALSE) and MCastFilterCount is zero • Multicast is being enabled and MCastFilterCount is greater than Snp->Mode->MaxMCastFilterCount • Multicast is being enabled and MCastFilter is NULL • Multicast is being enabled and one or more of the addresses in the MCastFilter list are not valid multicast MAC addresses
EFI_DEVICE_ERROR	<ul style="list-style-type: none"> • One or more of the following conditions is TRUE: • The network interface has been started but has not been initialized • An unexpected error was returned by the underlying network driver or device
EFI_UNSUPPORTED	This function is not supported by the network interface.

EFI_SIMPLE_NETWORK.StationAddress()

Summary
